Policy summary pop-up: The policy summary pop-up provides a quick and easy reference to the rule details defined in the policy and their severity. With this pop-up, it is easier to understand which policy is applied to different folders without navigating back and forth between policy and assign tabs in the policy manager. It also helps you quickly decide which policy you want to assign to a particular folder.

This policy summary pop-up is provided in the following tabs:

- Policy tab: Click the number of rules.
- Assign tab: Click either the assigned policy or the number of rules in the **Assign policy** option.

Policy behavior on folder operations

The following table describes the behavior of the policies when certain operations are performed on the folder.

Folder operation	Policy behavior
Create	Folder inherits the policy from the nearest parent folder
Rename	Folder retains the current policy
Move	Folder either retains the current policy or inherits the policy from the nearest parent folder
Delete	The policy assigned to the folder is removed

When you run code analysis on a bot, it uses the applicable policy for the folder (assigned or inherited) where the bot is located.

Code analysis rules

Rules are the foundation of code analysis. They are used to evaluate the bot logic. Rules can be simple or complex depending on the evaluation performed. Rules include coding practices that can be verified. They apply to packages and actions in the automation code.

A rule consists of a unique RULE_CODE and a description which indicates the nature of the evaluation to be done on the code. You can use the severity levels (low or high) to emphasize the criticality of the rule.

The following table lists the rules and their description that can be used with code analysis:

Rule code	Group	Title	Rule description
ACT-GEN-001	Actions, general	Action Maximum	The number of actions in the bot cannot exceed the specified maximum
ACT-GEN-002	Actions, general	Try-Catch Coverage	All the non-comment actions within the bot logic must be within a Try/Catch block.
ACT-GEN-003	Actions, general	Infinite Loop Detection	Mandates the check for infinite loops in the bot logic
VAR-NMG-001	Variables, naming	Variable Name Pattern	Variable names must match the specified naming pattern
VAR-NMG-002	Variables, naming	Variable Name Length	Variable names must be within the specified minimum and maximum character length
VAR-USG-001	Variables, usage	No Unused Variables	All the variables must be used within the bot
ACT-COM-001	Actions, comments	Mandatory Header Comment	The first action in the bot must be a Comment action
ACT-COM-002	Actions, comments	Comment Coverage	The number of Comment actions must be equal to or greater than the specified percentage of total command actions
VAL-HCV-002	Values, hard coded values	No Hard Coded Delay	The delay time in the Delay action must be set using a variable
VAL-HCV-003	Values, hard coded values	No Hard Coded File Path	The file or folder path must be set using a variable
VAL-HCV-004	Values, hard coded values	No Hard Coded Email Address	The command action field must not contain a hard-coded email address
ACT-ERR-001	Actions, error handling	No Empty Catch	The catch block cannot be empty

Rule code	Group	Title	Rule description
ACT-ERR-002	Actions, error handling	Mandatory Catch Logging	The catch block must contain a Log to File action
ACT-ERR-003	Actions, error handling	Mandatory Catch Screen Capture	The catch block must contain a Screen capture action
ACT-ERR-004	Actions, error handling	Mandatory Catch Line Reference	The catch block error must contain the reference line number
ACT-LOG-001	Actions, logs	Log to file coverage	The bot logic must contain the specified ratio of Log to file actions

Checking out code analysis results

As a Bot Creator (RPA developer) or Citizen Developer, you can use code analysis to check and fix any coding errors in your bots. You can develop automation based on configured code analysis policies and predefined rules.

With code analysis, you can improve the reliability of your bots by implementing coding best practices such as variable naming conventions, comment coverage, and error handling. Building bots conforming to the predefined guidelines or rules helps you to identify possible errors during bot development. This reduces bot failures in the production environment. You can run code analysis in both your private and public workspaces and view the results.

With code analysis (available from the Bot editor), you get the following benefits:

- Run code analysis as required.
- Get tooltip guidance for compliance with rules
- Integration with Assistant for accounting and guidance.

Code analysis results

To view the results of code analysis, go to the **Automation** page, and check the **Code Analysis results**. This column shows a summary status of the code analysis results for each automation file. The following details of each status are available:

- N/A: You will see the not applicable status for any of the following reasons:
 - Code analysis does not apply to the object because the object is not a Task Bot file.
 - There is no policy assigned to the Task Bot file or folder. When a Task Bot file or folder is in N/A status, row level actions for run code analysis option is not shown. Code analysis will not automatically run on these Task Bot files that have the N/A status.
- Not Scanned: Code analysis has not been run on the bot.
- High severity: The bot has at least one high severity violation.
- Low severity: The bot has at least one low severity violation, but no high severity violations.
- No violations: There are no code analysis violations in the bot.

The following image shows an example result from code analysis:

Automation

Automation Private Bot Store

Private bots and files cannot be viewed by other people. If a bot or file has been checked out from the Public tab, it can be viewed and run by other people, but cannot be edited.

Name Search

Files and folders (5)

Type	Name	Status	Source version	Code Analysis results	Size	Last modified	Modified by
Folder	bulk_checkin	N/A	N/A	N/A	N/A	3 minutes ago	bot_creator
Task Bot	Excel find text which is no...	New	N/A	Not scanned	16.39 KB	23 minutes ago	bot_creator
Task Bot	test_code_analysis	Checked out	3	High severity	2.75 KB	21 hours ago	bot_creator
Task Bot	test_migration	New	N/A	Low severity	1.27 KB	24 minutes ago	bot_creator
Task Bot	test1	New	N/A	Not scanned	2.32 KB	24 minutes ago	bot_creator

100 per page

Note: The status of the bots in the code analysis results column is set to not scanned for the following scenarios:

- The bot is edited in the private workspace.
- Code analysis is disabled by the administrator or there is a change in any of the rule configuration in the applicable policy for the Task Bot file.

Reviewing results in Bot editor

When you create a bot or modify an existing bot and then save the bot in the Bot editor, code analysis is initiated in the background, and the results are displayed in the Assistant. The code analysis header shows the total count of violations in the bot. You can expand the code analysis option, select a specific object and view the following attributes:

- Applicable object: Displays the bot, variable, action, and action attribute.
- Rule code: Unique RULE_CODE ID.
- Severity: High or low.
- Rule text: Description to indicate the nature of evaluation to be performed on the code.

The following image shows an example of code analysis displayed in the Assistant:

The code analysis results are displayed in the following order:

Attribute	Rules violated
Bot	<ul style="list-style-type: none"> Mandatory header comment Comment coverage Action maximum
Variable	<ul style="list-style-type: none"> Variable name pattern Variable name length No unused variables
Action	<ul style="list-style-type: none"> No hard-coded delay No hard-coded file path No hard-coded email address No empty catch Mandatory catch logging Mandatory catch screen capture

The code analysis header displays the count of objects with a violation error within the bot. Each object can have either low or high severity. The violation is displayed with the attribute followed by the line number and the severity. All the high severity errors are displayed first. Navigate to the corresponding line in the bot that has the violation, rectify the violation, and save the bot.

You must save the bot to see the latest code analysis results in the Assistant.

Code analysis violations and policy details in Bot editor

Pro and Citizen Developers can see the code analysis violations in actions at the canvas level. A violation indicator is available for flow and list views, enabling Pro and Citizen Developers to

quickly see and correct any actions in their automations that have code analysis violations. Code quality is enhanced when developers can easily determine violations and adhere to best practices when they are developing automations.

Pro and Citizen Developers no longer need to navigate to the policies page to view the applied policy and the rules contained in the policy. They can see the current code analysis policy and their rules from directly within the Bot editor from the drop-down menu (access from the three vertical ellipses in the upper right of the Bot editor) . This helps the users who do not have **View policies** and **Manage policies** permission to view current policy and their rules while editing the automation in the Bot editor itself instead of just viewing the violation.

System-created variables

Variables created by the system such as input or output variables, package-suggested variables, or auto-generated variables (window variables) use the default variable naming case convention from code analysis or Pascal case if no format is defined in code analysis rule.

Audit log

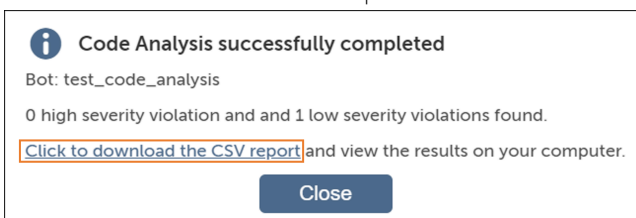

When code analysis is initiated either by saving a bot or running code analysis in the Bot editor, the information is captured in the audit log. The following details are captured:

- Bot name
- User information
- The method through which code analysis is initiated (save option or run code analysis option)
- Time taken for the code analysis to run including details such as the number of code lines if captured by code analysis process
- Total number of violations
- Details of the violations

Code analysis reports

You can access the code analysis report from the **Automation** page after running code analysis. The report is in the form of a downloadable CSV file.

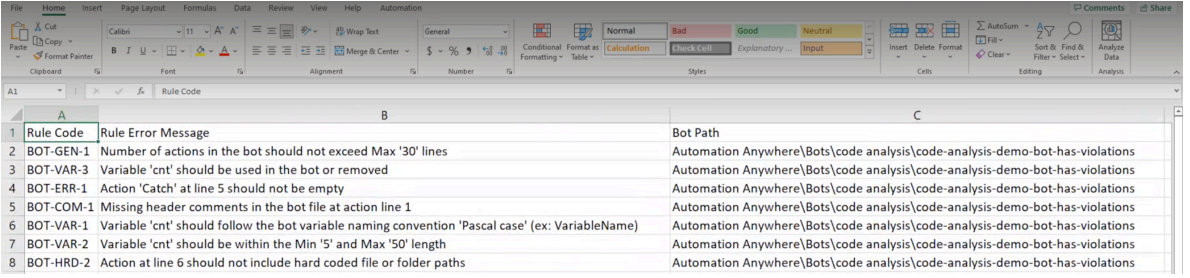

You must have **View content** permission to download the code analysis results in CSV format.

The report contains the results of the code analysis policy. It details the violation, the location of the violation, and the bot file location. The code analysis report consists of the following:

- Rule code
- Rule error message description (with location of bot file as appropriate)
- Location of the bot

The following image shows an example code analysis

Rule Code	Rule Error Message	Bot Path
BOT-GEN-1	Number of actions in the bot should not exceed Max '30' lines	Automation Anywhere\Bots\code analysis\code-analysis-demo-bot-has-violations
BOT-VAR-3	Variable 'cnt' should be used in the bot or removed	Automation Anywhere\Bots\code analysis\code-analysis-demo-bot-has-violations
BOT-ERR-1	Action 'Catch' at line 5 should not be empty	Automation Anywhere\Bots\code analysis\code-analysis-demo-bot-has-violations
BOT-COM-1	Missing header comments in the bot file at action line 1	Automation Anywhere\Bots\code analysis\code-analysis-demo-bot-has-violations
BOT-VAR-1	Variable 'cnt' should follow the bot variable naming convention 'Pascal case' (ex: VariableName)	Automation Anywhere\Bots\code analysis\code-analysis-demo-bot-has-violations
BOT-VAR-2	Variable 'cnt' should be within the Min '5' and Max '50' length	Automation Anywhere\Bots\code analysis\code-analysis-demo-bot-has-violations
BOT-HRD-2	Action at line 6 should not include hard coded file or folder paths	Automation Anywhere\Bots\code analysis\code-analysis-demo-bot-has-violations

report:

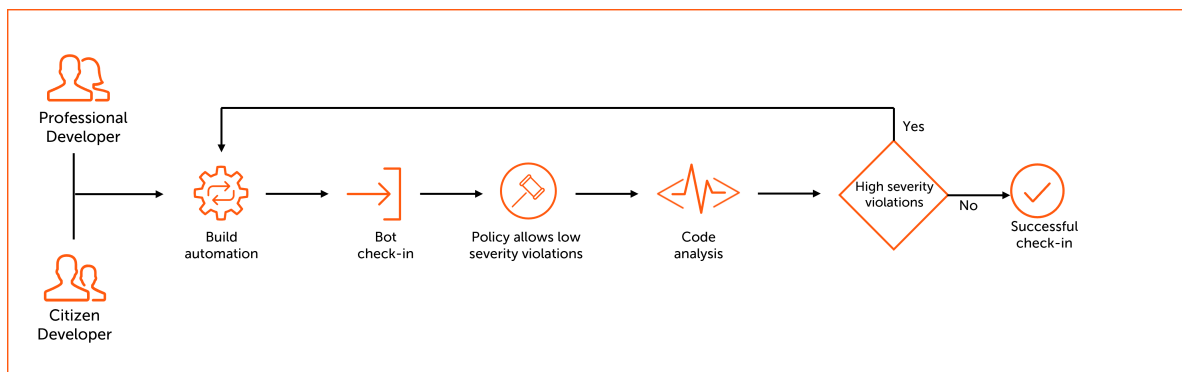

Code analysis enforcement

As an administrator, you can enforce code analysis when developers check in bots to the public workspace. You can restrict the RPA developers or Citizen Developers from checking in automations that contain code analysis violations based on permissions assigned to them in their custom role.

Code analysis enforcement is based on a combination of the following:

- Policies applied to folders
- Permissions allocated to users in their custom roles

Code analysis policies apply to files in the **Automation** tab. You can configure the same rule with two different policies but with different severity levels; one with low severity and the other with high severity. By using policies with rules configured at different severity levels, you can focus the enforcement to specific automation projects.

Code analysis enforcement permissions

The following code analysis enforcement permissions are available:

- **Enable enforcement for bot check-in:** A default permission for all roles which allows the user to check in the automation file if it has no code analysis violations.
- **Allow check-in with low severity violations:** This optional permission allows the user to check in the automation file if it has low severity code analysis violations.
- **Allow check-in with high severity violations:** This optional permission allows the user to check in the automation file if it has high severity code analysis violations.

Important: Starting with Automation 360 v.29, all the system roles (such as AAE_Basic or AAE_Admin) will have only the permissions to check in bots with no violations. All the custom roles (user-defined roles) are updated to contain both the permissions to check in with low and high severity violations. For enforcement, you should edit your custom roles to restrict check-in. If you use only system-defined roles for your users, to configure enforcement, you must create new roles to assign the appropriate permissions to check in bots with violations.

Use different roles and permissions to restrict automation file check-in based on the skill level of the developer. For example, you can have policies with low and high severity violations applied to a folder. You might have Citizen Developers who are assigned the permission to check in bots with both high and low severity violations, whereas the RPA developers might have the permission to check in bots with no violations or only low severity violations.

You can use different policies on different automation projects and set different rule severity levels for different policies and environments. For example, in the testing environment, you can have policies where all rules are set to high severity, and the RPA developers can only check in bots with low severity or no violations.

Example

The following example shows three automation files with their code analysis results::

Automation files	Code analysis results
File 1	10 rules with high severity violation
File 2	7 rules with high severity violation 20 rules with low severity violation
File 3	10 rules with low severity violation

The example includes three users with assigned roles:

User	Role assigned
Alice	Role 1
Bob	Role 2
Carol	Role 1, Role 2

- Users in role 1 can check in bots with results of high severity violation.
- Users in role 2 can check in bots with results of low severity violation.

The code analysis enforcement for these users are as follows:

- Alice can check in file 1.
- Bob can check in file 3.
- Carol can check in file 1, file 2, and file 3.

Configure and assign code analysis policy

As an administrator or a user with view and manage policy permissions, you can configure multiple named policies to define coding best practices to improve the reliability of automations by reducing errors.

Ensure that you have the following permissions:

- View policies
- Manage policies

These permissions allow you to view, edit, and assign policies that define how developers can build automations. They also allow the assignment of policies to folders for which you have access.

- Create policies in the **Policies** tab.
 - a)** In the Control Room, navigate to **Administration > Policies**.
 - b)** Select the **Policies** tab.
 - c)** Select the **Create policy** icon at the top of the policies table.
 - d)** Enter a meaningful name for the policy.
 - e)** Optional: Enter a descriptive comment for the policy.
 - f)** In the **Rules** section, use the on and off slider in the rule tiles to turn on and configure one or more rules.
 - g)** Select the **Severity** as either **Low** or **High** to highlight the criticality of the rule.
 - h)** Click **Save changes** to create the policy.
A notification appears indicating the policy details are successfully saved.

See the following video to learn how to create named policies:

- Assign a policy to multiple folders in the **Assign** tab.
 - a)** In the Control Room, navigate to **Administration > Policies**.
 - b)** Select the **Assign** tab.
 - c)** Select one or more folders.
 - d)** Select the **Assign policy for checked items** icon at the top right of the folders table.
A policy selector window appears indicating the selected folder name or the number of selected folders.
 - e)** In the policy selector window, search for a policy using the search tool at the top.

Note: Each policy has a summary of the number of rules.

- f) Select the policy to assign to the selected folders.
- g) Click **Assign** to assign the policy to the selected folders.

See the following video to learn how to assign named policies:

Run code analysis

As a Bot Creator (RPA developer) or Citizen Developer, you can run code analysis to evaluate your bots for any coding errors. You can develop automations based on the code analysis policies and predefined rules.

You must have **View content** permission to download the code analysis results in CSV format.

- You can run code analysis only on bots that are error-free. If your bots contain errors, the **Run Code Analysis** option is not enabled. Resolve the errors in your bot to see the **Run Code Analysis** option.
- Code analysis automatically runs on all the bots with the **Not Scanned** status in the public workspace, thereby providing visibility on the coding best practices for all the bots in the public repository. Code analysis runs every five minutes and scans 1000 bot files in five minutes.
- Code analysis is not invoked on API bot files.
- When you run code analysis, if there is a change in the code analysis results status, the last modified time of the bot is updated.

- Run code analysis in the private workspace:
 - a) On the **Automation** page, select the bot, click the actions menu (vertical ellipsis), and click **Run Code Analysis**.
A message is displayed indicating that code analysis is successfully completed, along with a file link with the result of the code analysis.
 - b) Click the file link to analyze the result of code analysis.
A CSV file with the result of code analysis is displayed.
 - c) Click **Close**.

- Run code analysis in the public workspace: Run code analysis by choosing one of the following options:

Option	Steps
Run Code Analysis	<ol style="list-style-type: none"> 1. On the Automation page, select the bot, click the actions menu (vertical ellipsis), and click Run Code Analysis. 2. Select the version of the bot for which to run code analysis: <ol style="list-style-type: none"> a) Latest version b) Product label 3. Click Continue. A message is displayed indicating that code analysis is successfully completed, along with a file link with the result of code analysis. 4. Click the file link to analyze the result of code analysis. A CSV file with the result of code analysis is displayed. 5. Click Close.
View history Task Bot	<ol style="list-style-type: none"> 1. On the Automation page, select the bot, click the actions menu (vertical ellipsis), and click View history Task Bot. All the versions of the selected bot are displayed on top showing the latest version. 2. Select a version of the bot, click the actions menu (vertical ellipsis), and click Run Code Analysis. A message is displayed indicating that code analysis is successfully displayed, along with a file link with the result of code analysis. 3. Click the file link to analyze the result of code analysis. A CSV file with the result of code analysis is displayed. 4. Click Close.

The following video shows the two ways of running code analysis in the public workspace:

Upgrade changes in code analysis policy for Automation 360 v.28 or later versions

For Automation 360 v.28 or later versions, there is a change in how policies are managed for code analysis. Advanced policy management provides the flexibility to gradually introduce code quality standards on existing and older projects, and apply firmer standards on newer projects.

If you have configured a code analysis policy in Automation 360 v.27 or earlier, this policy is migrated to a named policy in Automation 360 v.28 or later versions. This preserves any previously configured policy as a named policy, so you can use it with the new named policies feature in Automation 360 v.28.

See [Code analysis policy management](#) on page 2106.

The new named policy will be named default policy and will be applied to the **Automation** page root folder. This policy is applicable to all automation code in all the folders. This is similar to the single policy feature in Automation 360 v.27 and earlier. You can make edits to restrict the default policy to a few folders or automations, and make changes to the enabled rules and their severity.

Notifications

Notifications is a built-in mechanism in the Automation 360 Control Room, which notifies users about various events. It is a centralized notifications repository in Automation 360 for all users to track relevant events.

The Notifications mechanism provides simplified information about possible risks, warnings, information, and success statistics of the Automation 360 platform and automation events. With the notifications feature, you can monitor, respond, reduce, and resolve critical risks in much quicker way. It allows you enable required event categories and be notified for the enabled events.

The diagram illustrates the notification settings interface and a mobile notification bar. On the left, three yellow callout boxes with icons describe the settings:

- Enable or disable notifications for all Control Room users:** Represented by a person icon with a key.
- Enable or disable notifications for individual users:** Represented by a group of people icon.
- Get notifications for enabled event categories through enabled channels:** Represented by a bell icon.

On the right, a screenshot of the 'Notification settings' interface is shown. It includes sections for:

- Enable/disable notifications for all users:** Contains toggle switches for 'Automation events' (Off), 'Platform events' (On), and 'Process events' (Off). Below these are radio buttons for 'Allow users to control notifications settings', with 'Disable' selected.
- Notification channels:** Includes a toggle for 'Email reports' (On) and a text input field for email addresses.

At the bottom, a dark mobile notification bar is shown with icons for back, help, location, and a highlighted notification bell icon.

Benefits

Notifications provide the following benefits:

- Maintain all the notifications from a centralized repository.
- Enhance ability to respond to critical or warning notifications.
- Stay organized with automated notifications to reduce and avoid future risks, and take possible actions.
- Improve productivity of users and the platform by being notified about updates such as Bot export and add or update package.
- Save time and increase notification efficiency because of a single centralized events repository.
- Increase relevance of notifications delivery through multichannel communication.
- Notify Automation 360 users about events through email report or instant email notification.

See the following video for an overview of how notifications are configured in the Automation 360 Control Room:

Prerequisites

- The Control Room administrator must enable the **Administration > Settings > Notification settings** to receive notifications. For more information, see [Administer notifications for Control Room](#) on page 2129.
- Control Room users must enable the required settings from the **Notifications** repository to receive notifications. For more information, see [Enable or disable event categories](#) on page 2131.

Components

- Notification icons and navigation:
 -  : Indicates no new notification.
 -  : Indicates new notification.
 -  : Indicates hover over action on the notification icon.
 -  : Indicates select action on the notification icon.
- Notifications panel:

The in-app notification panel provides a comprehensive view of all the event notifications with notification summary and details. For more information, see [Getting started with Notifications](#) on page 2120.
- Notifications filter

The in-app notification panel displays all the notifications as a single list. You can enable the **Attention needed** filter to view and categorize high-risk and cautionary events such as:

 - Stop or impact execution of scheduled tasks or processes

- Tasks not running as expected or completed with minor recoverable errors.
- **Settings:**

Enable and disable the notifications for **Automation runtime events** and **Platform** events. You can also enable **Email report** channel to receive notifications through email.

Getting started with Notifications

The notifications repository provides simplified information that users can track for possible risks, warnings, and success statistics of various Automation 360 events.

When you enable required event categories, you receive notifications through the notifications repository. New notifications display with the () icon.

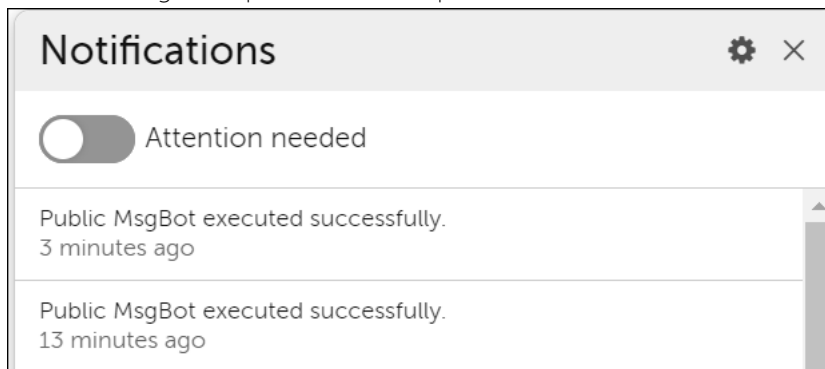

To start working with notifications, set preferences for the following event categories and notification channels:

Event categories

Events are at the core of the monitoring framework. Users must be able to monitor event continuously, and receive constant notifications. Automation 360 provides notifications for the following events:

- [Automation events](#) on page 2126
- [Platform events](#) on page 2127
- [Process events](#) on page 2128

The following example shows an export bot event notification:

Notification channels

Notifications are sent through integrated channels used to organize and manage the notifications. Automation 360 send notifications through the following channels:

Notifications panel

This is the default notification channel. The notifications panel provides a summarized view of all event notifications. It is a list of all the events across the Control Room. For more

information, see [Notification summary and details](#) on page 2124.

Note: The maximum number of days these notifications are available in the Control Room notification panel are:

- Attention needed: 4
- Other notifications: 2

Email notifications

These notifications generate emails to the opted-in users only. For more information about how to opt-in for email notification, see [Enable or disable event categories](#) on page 2131. There are two types of email notifications:

- Instant notifications: Instant email notification is sent to a user's registered email address.

The following sample shows an email sent for an instant notification:

Hello,

You have the following email from your Control Room administrator
john.doe@xyz.com

Type	Details
Information	Category: Platform events Time occurred: 19 Jul 2023 11:09:30 Your user account has been activated for informational purposes. If you have not already done so, please visit Anywhere's control room now and grant access to your account.

Bonjour,

Vous avez reçu le-mail suivant de la part de l'administrateur
john.doe@xyz.com

Type	Détails
Informations	Catégorie: Événements de la plateforme Temps écoulé: 19 Jul 2023 11:09:30 Votre compte utilisateur a été activé pour des fins informatives. Si vous ne vous êtes pas encore connecté, veuillez visiter control room Automation Anywhere et accorder l'accès à votre compte.

- Email report: Email report notification is sent to a user's registered email address twice a day at a fixed time.

The following sample shows an email sent for an email report:

Hello,

You have the following email from your Control Room administrator:

john.doe@xyz.com

Summary Report

19 Jul 2023 07:57 AM - 19 Jul 2023 07:56 AM

Attention needed: 0

Information: 8

Total notification: 8

Information

Category/Time occurred	Details
Automation events 19 Jul 2023 07:57:26	Bot execution completed successfully.
Automation events 19 Jul 2023 07:57:08	Bot execution completed successfully.
Platform events 19 Jul 2023 07:56:51	AAIN1936Z4E9 updates for Setting DeviceT
Platform events 19 Jul 2023 07:56:22	Office 365 Excel package 2.13.2 is now available
Platform events 19 Jul 2023 07:56:20	PDF package 3.9.0 is now available in the c
Platform events 19 Jul 2023 07:56:20	Office 365 Calendar package 2.13.1 is now
Platform events 19 Jul 2023 07:56:19	Microsoft 365 Outlook package 1.1.4 is now
Platform events 19 Jul 2023 07:56:18	Document-Extraction package 3.30.5 is now

Note: Notifications that are sent as Instant notifications are not included in the Email report and vice-versa. Based on the event type, notifications are sent either as Instant notifications, or Email report. You cannot configure these notifications.

Notification summary and details

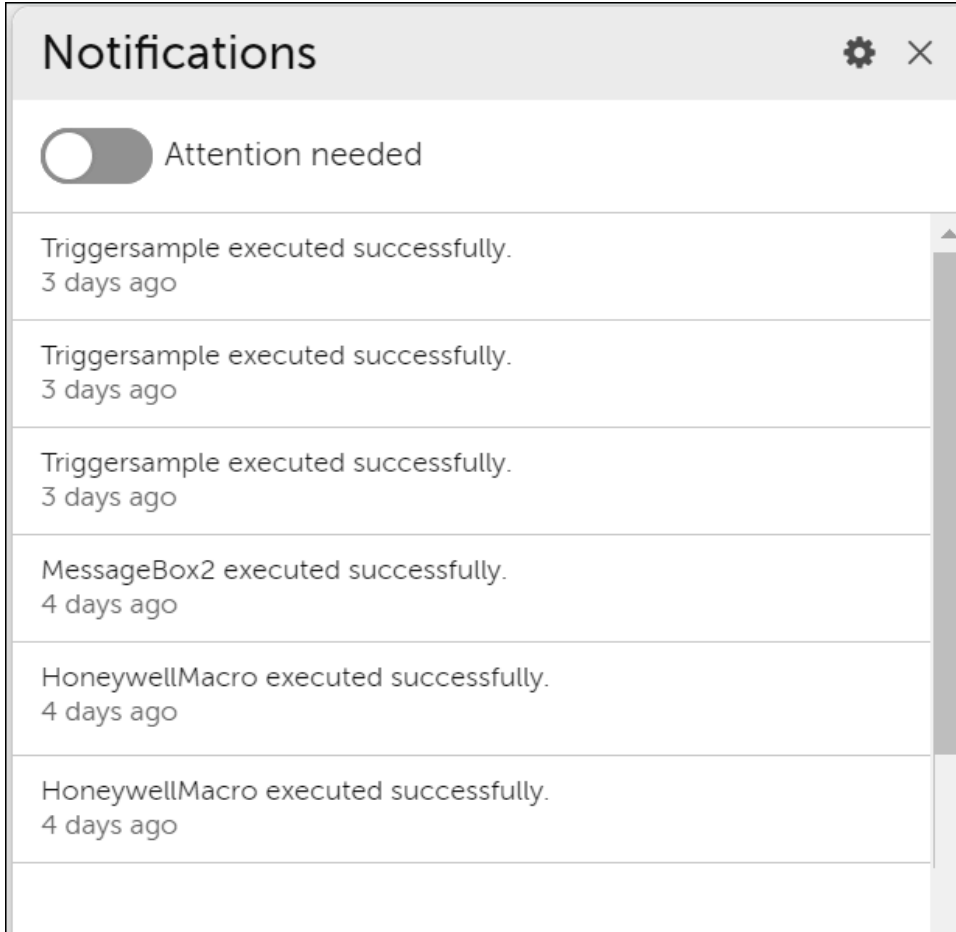

After you enable the required event category, corresponding event notifications are sent through the **Notifications** repository. The notification summary displays an event description with the call-to-action (CTA) link (if applicable) in the description. The notification summary provides information about the event such as successful or unsuccessful execution of bot, license or user related events, and on. The CTA link in notification summary redirects you to the appropriate page or wizard, thus increasing the notification's effectiveness.

Note:

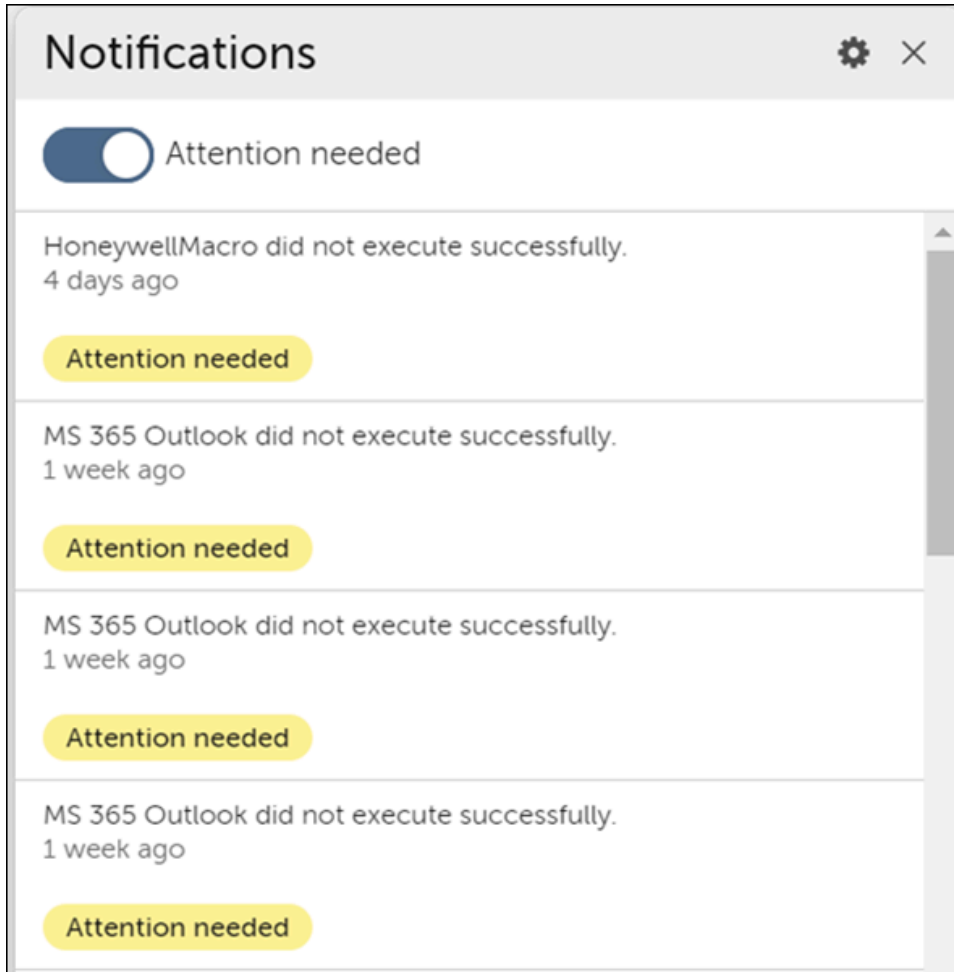

- The notification summary varies based on the event type.
 - If a notification have additional details associated with it, you can expand the notification summary by using the expand icon in the top-right corner of the notification.
-

The following images are sample event notifications for a bot execution events:

- Event notification for a successful bot execution:

- Event notification for an unsuccessful bot execution:

Automation events

The automation event category is a group of notifications that contains bot-related events such as bot execution successful or unsuccessful.

These notifications are sent to users based on the permissions defined in the Automation 360 platform, and to users who have performed specific tasks, such as export bot. Based on permissions to monitor the bot execution, notifications are sent to the following users:

- Users who starts the bot and have access to monitor the bot execution.
- Users who have access to the bot and can monitor other user's bot execution.
- Users who have access to the bot and can monitor execution based on their respective folders.

Note: If a user is common in all the preceding scenarios, only one notification is sent to the respective users for all the scenarios.

The following table lists examples of the automation event and its severity:

Event name	Users notified for the event	Type of email notification
Bot execution successful	Control Room user who started the bot execution	Email report
Bot export successful	Control Room user who exported the bot	Email report
Bot export unsuccessful	Control Room user who exported the bot	Email report
Bot execution unsuccessful (Application or Data related error, Bot start-up issue, or Bot in unknown or suspended state)	Control Room user who started and is monitoring the bot execution	Email report
Bot import successful	Control Room user who imported the bot	Email report
Bot import unsuccessful	Control Room user who imported the bot	Email report

Platform events

This category notifies you about events related to the Automation 360 and package updates, device pool, and licenses.

These event notifications are sent to users based on their role and permissions defined in the Control Room. The following table lists examples of the platform events and its severity:

Event name	Users notified for the event	Type of email notification
Add a device to, or remove a device from a device pool		
Add or update package	All Control Room users	Email report
Create or update device pool	Device pool owners	Email report
Enable or disable user account	Notifies only respective users about user account related events such as account enabled or disabled. You can take necessary actions to manage or retain your user account.	Instant notification

Event name	Users notified for the event	Type of email notification
Expired token	<p>An email notification sent to users who have the Manage connections permission. This static information notifies users about events related to expired tokens and provides steps to complete the task and re-authenticate for new set of tokens.</p> <ul style="list-style-type: none"> • Shared tokens: Notification is sent only when the token status is set to expired. • User specific tokens: Notification is sent only one time, when the token is identified as expired. 	Instant notification
Invalid login attempts	<p>Email notification sent to all users who exceeded the maximum allowed login attempts.</p> <hr/> <p>Note: A Control Room administrator configures the number of maximum allowed invalid login attempts through the Settings > Security settings. For more information about the the Lock the user out after unsuccessful login attempts option, see Security settings on page 1730.</p> <hr/>	Instant notification
License over subscription or consumption	Email notification to all users with a Manage license permission	Instant notification

Process events

The process events category notifies you about Automation Co-Pilot for Business Users (Automation Co-Pilot) events. This category includes events related to requests, tasks, and workflows.

When you work with Automation Co-Pilot forms or processes in applications such as Salesforce, Workday, browsers, and desktops for end-to-end process automation, the Control Room notifies you about the request and task events through notifications.

The following table describes various Automation Co-Pilot events:

Event name	Users notified for the event	Type of email notification
Assigned to Me	User assigned to the task	Email report
My Task Expired	User assigned to the task	Email report
Request Cancelled	<ul style="list-style-type: none"> Member of the creating team Creator of the request All previous submitters 	Email report
Request Completed	<ul style="list-style-type: none"> Member of the creating team Creator of the request All previous submitters 	Email report
Request Failed	<ul style="list-style-type: none"> Member of the creating team Creator of the request All previous submitters 	Email report

Administer notifications for Control Room

As an administrator, you can manage notifications for the Control Room by disabling various notification categories and channels.

Login to Control Room as an administrator.

You can manage notification settings for all the Control Room users and view the audit log information to track user activities.

Note: All the event categories are enabled by default.

1. Navigate to **Administration > Settings > Notification settings**.
2. To enable or disable the required event categories, click **Edit**.
3. Optional: Manage the event categories based on your requirements. For more information about which event category to enable or disable, see [Event categories](#) on page 2120.
 - When an administrator enables the event categories, those are applicable to all the Control Room users.
 - If the Control Room administrator disables one of the event categories, then individual users can view only the enabled event categories in the Control Room **Notifications settings** window.
 - If the Control Room administrator disables all the event categories, then individual users cannot view any of the event categories in the Control Room **Notifications settings** window.
4. Click **Save changes**.

Note: Notifications audit logs to track user activities are available at the **Administration > Audit log** page. For more information, see [Audit log](#) on page 2068.

Manage notification channels

As a Control Room administrator, you can manage notification channels through which you want to notify all the Control Room users.

- Login to Control Room as an administrator.
 - For On-Premises users, navigate to **Administration > Settings > Email** and enter an email address in the **From this email address** field to manage emails. For more information, see [Edit email notifications](#) on page 1758.
-

Note: This setting does not apply to Cloud users. The region-specific email addresses deliver the notifications in their respective clouds.

After you enable the required event categories, enable the required notification channel through which Control Room events are notified to the opted-in users. This feature helps you to notify users through email about events such as a planned maintenance activity. It is useful when you have a dedicated support team for managing the RPA operations.

Note: The email channel is disabled by default.

1. Navigate to **Administration > Settings > Notification settings**.
 2. Click **Edit** to enable or disable the required notification channel.
 3. Enable the required notification channel. For more information about notification channels, see [Notification channels](#) on page 2120.
-

Note: Notification channels enabled by an administrator are applicable to all the Control Room users.

4. Specify the email address or email distribution list to whom you want to send the email report.
-

Note:

- You can specify multiple email addresses and email distribution lists separated by comma.
 - You can send an email notification to a specific email distribution list.
 - You cannot send email notifications to public domain addresses such as gmail.com, yahoo.co.in, and so on.
-

When you specify the email addresses, you confirm that the specified email address or distribution list have permissions to receive email notifications from Automation 360.

5. Click **Save changes**.

Lock event categories

As a Control Room administrator, you can lock the set preferences. With this feature, a Control Room administrator can manage a user's access to the event categories that are already set.

Login to Control Room as an administrator.

If this setting is enabled, individual users can enable or disable the required event categories. Otherwise, this setting locks the preference that a Control Room administrator had set.

For example, for attended automation users, the automation administrator does not want individual users to change these settings. To enforce this policy, a Control Room administrator can lock the required preferences and notifications only for those enabled event categories are sent to the users.

1. Navigate to **Administration > Settings > Notification settings**.
2. Click **Edit** to enable or disable the required notification channel.
3. For the **Allow users to control notifications settings**, select one of the following options.
 - **Enable:** When you enable this setting, individual users can change the notification settings in their Control Room instance.
 - **Disable:** When you disable this setting, the notification settings set in the **Administration > Settings > Notification settings** section are locked and individual users cannot change the notification settings in their Control Room instance.

Note: When **Allow users to control notifications settings** is disabled, all the Control Room users are notified about events based on the enabled event categories in the **Administration > Settings > Notification settings** section.

4. Click **Save changes**.

Enable or disable event categories

As an individual user, you can enable or disable the required events categories to receive notifications, and control notifications traffic in your Control Room instance.

Ensure that the required event category is enabled by Control Room administrator.

1. Click the **Notifications** () icon.
2. Click the **Settings** () icon in the **Notifications** window.
3. Enable the required event category and close the **Notifications settings** window. For details about which event category to enable, see [Event categories](#) on page 2120.

Note: The Control Room administrator manages the disabled event categories.

Enable email report channel

As an individual user, you can use the email report channel to notify Control Room users about various events through emails.

Ensure that the required email report channel is enabled by Control Room administrator.

Email notifications are sent as an instant notification or email report based on the event severity identified by the Automation 360 platform. The email report channel is disabled by default.

1. Click the **Notifications** () icon.
2. Click the Settings () icon in the **Notifications** window.
3. Enable the **Email report** option to receive email notifications.
An email report, containing the Control Room URL and time duration when the report was generated, is sent to the specified email addresses or email distribution list.

Note: When you enable the email report channel, consider the following information:

- If the Control Room administrator does not enable the **Email report** channel, then individual users cannot enable or disable this option. As a result, individual users cannot be notified through emails.
 - If the Control Room administrator disables the **Email report** channel for a certain duration (for example, maintenance activity over weekend), individual users cannot receive email reports for that duration.
 - The email report is sent to all email addresses and distribution lists specified by the Control Room administrator based on the enabled event categories.
 - If an event is critical and marked for instant notification, then an email notification is sent immediately when the event occurs. Otherwise, it is sent as a part of the email report but the email notification not included in both instant notification and email report.
 - A single email report is sent for all bot events.
 - An email report is sent twice a day, at a fixed time that is 8 AM (PST) and 4 PM (PST).
-

Capabilities supporting notifications

With Notifications, you are notified about specific events in Automation 360, such as bot execution tasks and updates to platform and functionalities.

Automation 360 supports notifications for the following capabilities:

Automation events

For example, export or import bot. When a bot is exported or imported, a notification is sent for these automation events. Based on the result (success or failure) of the export or import bot functionality available in the platform, you receive a notification that contains the event details. This notification is sent only to the user who exported or imported the bot.

For a list of automation events, see [Automation events](#) on page 2126.

Platform events

For example, add or update package. When a package is added or a new package version is released in the Control Room, you are notified about this platform event. This notification is sent to all the Control Room users who have the **View package** permission. Based on your role and package permissions, you can view event notifications. For package versions information, see [Packages available in Automation 360](#) on page 2225.

Note: For custom packages, a notification is sent only to the corresponding customer and not to all the Control Room users.

For a list of platform events, see [Platform events](#) on page 2127.

Process events

For example, notifications in embedded automations. Notifications are integrated in business applications (such as Workday, Salesforce) to provide business users updated information about automation events initiated from these business applications. Additionally, you can view these notifications through the Control Room notifications panel. Based on your role and permissions in the Control Room and business applications, you receive a notification. For more information, see [Automation Co-Pilot status and notifications](#) and [Automation Co-Pilot for Business Users supported features](#) on page 3162.

For a list of process events, see [Process events](#) on page 2128.

Control Room log files

Various types of information about the Control Room are captured in different log files. You can analyze these log files when the Control Room or a bot encounters an error and identify the root cause for that error.

Overview

The log files capture information about the errors encountered by various components of the Control Room such as the Bot Store, devices, and license. You can use the information in the log files to identify the root cause of an error and resolve that error.

Log file locations

The Control Room log files are available at `C:\ProgramData\AutomationAnywhere\Logs` on the machine on which you have installed the Control Room. The log files are named `WebCR_<COMPONENT-NAME>`, for example, `WebCR_BotStore`, `WebCR_Devices`, and `WebCR_License`.

You can refer the following log files for the Control Room.

WebCR.log	Contains log entries related to the initialization of the Control Room and messages, if any.
-----------	--

WebCR_UserManagement.log	Contains log entries related to the user management module.
WebCR_Ignite.log	Contains log entries related to the Apache Ignite or caching system.
WebCR_ServerRepository.log	Contains log entries of the server repository related functions.
WebCR_CredentialVault.log	Contains log entries of Credential Vault related function calls.
WebCR_Hibernate.log	Contains log entries related to the Hibernate system, ORM mapping and Query system, ActiveMQ messaging subsystem, and so on.

Build automations

Automation 360 provides a browser-based, intuitive experience for users to easily automate tasks and powerful tools for developers to build process automation, delivering security, and governance.

Overview

Our Automation Workspace is a web-based workspace that provides the tools and capabilities to create, upload, and deploy bots to automate repetitive tasks and processes. It includes the Control Room, Bot editor, Bot Runners, Bot Creators, and Credential Vault.

Automation Workspace provides the following capabilities:

- Automate fast and customize with an actions library for the complicated processes
- Get full visibility and orchestration, from scheduling to automating workloads, with the Control Room
- Assign and manage role-based access with full control and audit trail of every event
- Multi-layered security from cloud to platform to bots ensures granular, privileged access to data.

Build bots

Use our Bot editor to create and edit bots on any device and from a web browser. See [Bot editor for creating bots](#) on page 2152.

Watch the following videos to get started on building bots:

- Short video on building your first bot:
- Detailed video with a step-by-step guide toward becoming an RPA developer:

For RPA courses, tutorials, certificates and more, visit: [Automation Anywhere University: RPA Training and Certification \(A-People login required\)](#).

Templates

Automation 360 provides (out-of-the-box) templates that you can use to quickly create and build new automations. These templates contain prebuilt automation code structure that you can select based on your business processes.

Overview

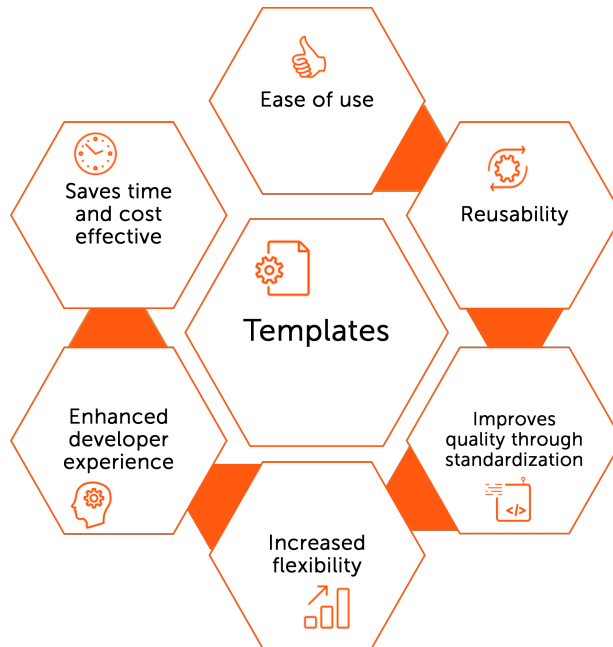

Important:

- Currently, predefined templates are not available in Automation 360. However, you can create and publish your own custom templates based on your business needs.
 - Currently, you can create templates only from Task Bots.
-

Templates enable teams to automate common business scenarios rapidly and are user-friendly for citizen developers because there is no need for coding skills. For example, the Payroll management team can use predefined templates to generate pay slips for the employees of an organization. Similarly, the Human resource team can use templates to automate processes such as application processing, interview scheduling, employment offers, and employee onboarding, offboarding, and exiting.

Benefits of templates

- Templates simplify the process of creating automations enabling citizen developers with low or no coding knowledge to use predefined templates for their business use cases.
- Professional developers can use predefined templates to quickly build and customize complex automations.
- Using prebuilt code structures reduces errors and enforces coding best practices.
- Templates enable you to start automation initiatives quickly and efficiently without having to re-enter duplicate information into several automations.
- Templates reduce cost, enhance productivity, and accelerate development.

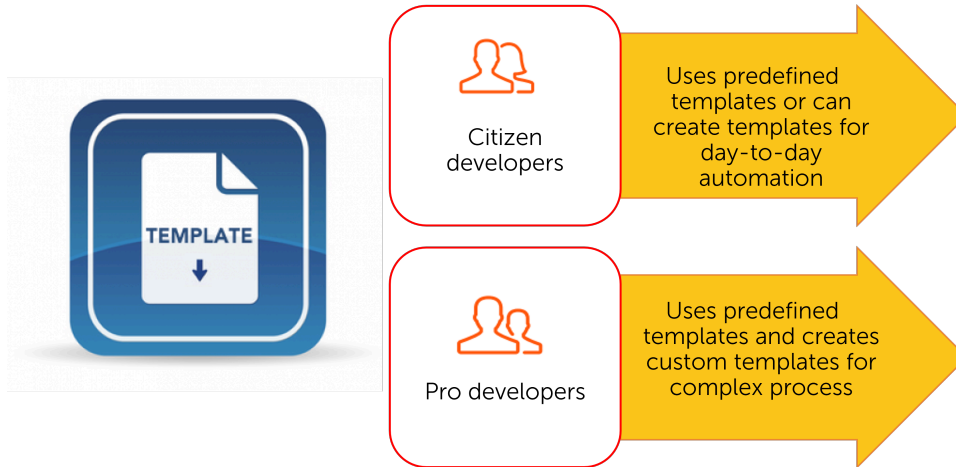

Templates for user roles

Professional developers: Lead or advanced developers can use, create new templates, or customize the existing ones to build automations.

- Enable developers to develop templates for more complex business cases.
- Improve the reliability of automations by reducing errors.
- Improve process efficiencies for reliable automations by adhering to coding best practices such as placeholders for comments, exception handling, logging, and so on.

Citizen developer: Business users can use predefined templates or create simple templates for their daily automations, such as desktop applications, data collection, data processes, request approvals, and task assignment.

- Templates for common business use cases enable quick and easy application development, ensuring quality.
- Ability to achieve automation goals by following a set structure of code which does not require an in-depth knowledge of packages, actions, or triggers for a specific business use case.

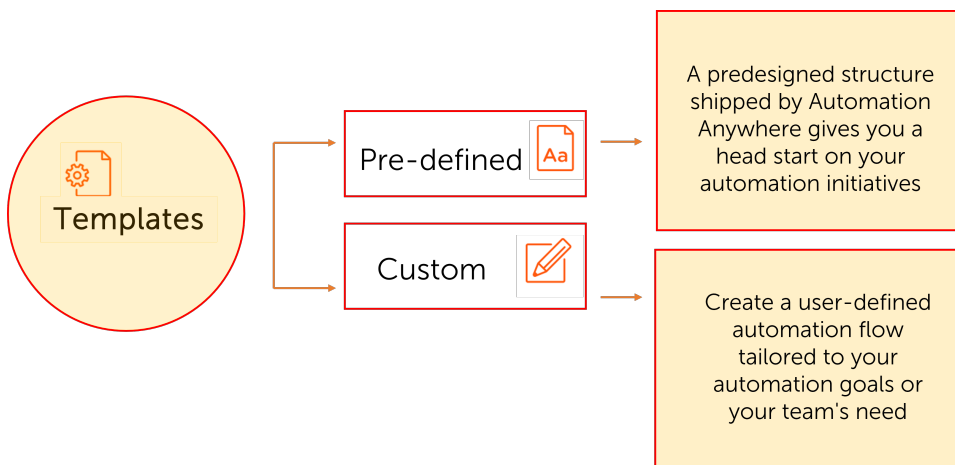

Permissions

To access the templates, you must have the following permissions:

- View my bots permission
- Additionally, you must have the following permissions on the folders containing the templates you want to update:
 - Check in
 - Check out
 - View content

Types of templates

Using templates

Templates in the private workspace are available only to those users who created them. Templates created in the private workspace can be made available to other users by checking in the template to the public workspace.

Role-based access control (RBAC) does not apply to templates. Depending on your folder or file level permissions where the template resides, you can access all the templates in the public workspace. For example, RBAC is set at the package level, and you do not have access to a particular package but you do have access to a specific template. In this case, you can access the templates but not the packages in the template. A message displays indicating you do not have access to that package.

The following video shows how to create and use templates.

Create template

Create a template to get a framework containing a list of steps that you can use to automate repetitive work.

For example, your organization runs a biweekly data backup to store and secure data on the cloud, and this process is being automated across multiple departments. Instead of each department building the automation from scratch, they can use templates to customize it based on their own unique requirements.

- This task is performed by a user who has a Bot Creator or Citizen Developer license.
- The user must have **View my bots** permission,
- To check in and check out the templates, user must have **Check in** and **Check out** on the folders of where the template resides.

Procedure

You can create a template using one of the following methods:

- Use an existing automation
 - 1.** Log in to the Control Room.
 - 2.** On the **Automation** page, open an existing automation.
 - 3.** Add new actions or modify the existing property values in the automation.
 - 4.** Click **Save as Template** to save the template.

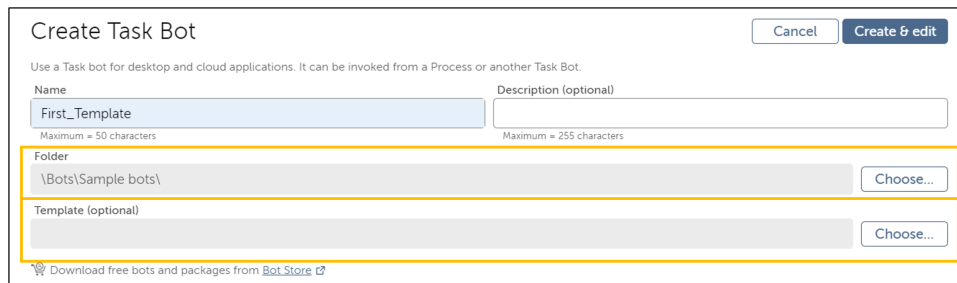

- Create a new template
 1. Log in to the Control Room.
 2. Create a new template.

Note: Currently, you can create a template only from a Task Bot. This option creates an automation as an intermediate step. If you do not plan to edit or use the automation, you can delete it.

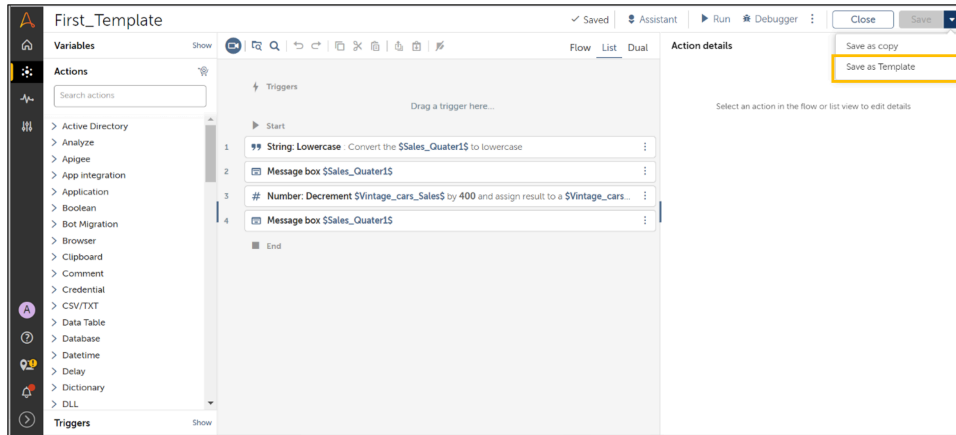

- a) On the left pane, click **Automation**.
- b) Click **Create new > Task Bot**.
- c) In the **Create Task Bot** window, enter the template name.
- d) Accept the default folder location: `\Bots\`.

To change the default template storage location, click **Choose** and follow the prompts.

- e) Click **Create and edit**.

3. Based on your use case, you create a custom template in the Bot editor using actions from the **Action** pane, and then select the **Save as Template** option.

4. In the window that opens, enter the template name, description, and path, and then click **Save**.

Edit a template

Use the **Edit template** option to add, modify, or delete actions and automation steps based on your business scenarios.

Note: You cannot edit a template in the public workspace. You can check-out the template from the public workspace to edit it in the private workspace.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.
A list of available templates and automations is displayed.
3. Perform the following steps to edit a new or checked-out template in the private workspace.
 - a) Click the actions menu (vertical ellipsis) and click **Edit Template**.
The template opens in the edit mode in the Bot editor.
 - b) Click any action in the editor that you want to update.
 - c) Edit the required fields.
You can modify the existing property values or delete actions.
 - d) If required, add new actions or files you want to add as dependencies.
4. Click **Save**.

Create automation from a template

You can use a template to build an automation. As a Citizen Developer or Professional developer, you can select from prebuilt templates and create new automations based on your automation goal.

- This task is performed by a user who has a Bot Creator or Citizen Developer license.
- The user must have **View my bots** permission.
- The user must have **Check in** and **Check out** permission on the folders of where the template resides.

1. Log in to the Control Room.
2. Create a new automation from templates.

- a) On the left pane, click **Automation**.
- b) Click **Create new > Task Bot from Template**.

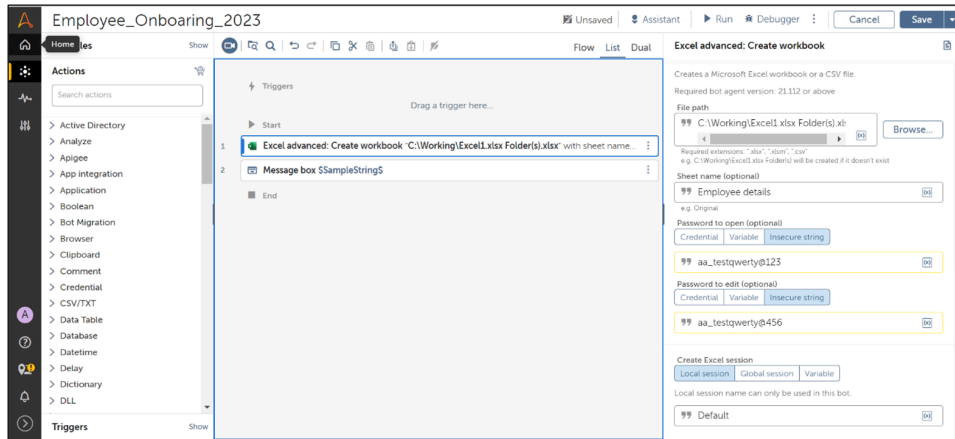

You will see all the available templates in the **Create Task Bot from Template** window.

- c) Search for a specific template in one of the following ways: search for the template name or description, or select the template.

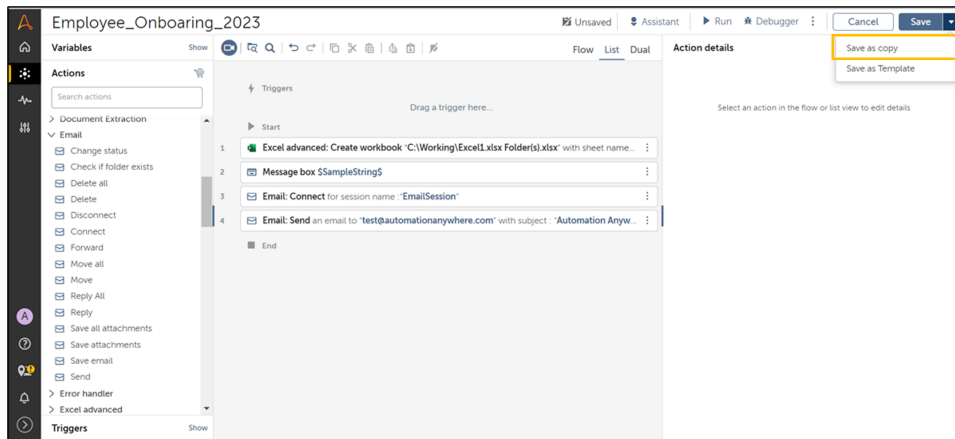

- d) Click **Continue**.
You can also click the **View template** icon to open template in the Bot editor and view it.
- e) In the **Create Task Bot from Template** window, enter the automation name.
- f) Accept the default folder location: `\Bots\`.
To change the default automation storage location, click **Choose** and follow the prompts.
- g) Click **Create and edit**.

After entering the automation details, the Bot editor is displayed. The automation structure is added to the canvas, and you can start editing a template.

3. If required add more actions to the workflow, edit the properties of the existing actions, or delete specific steps.
4. Click **Save**.

Additionally, you can select **Save as copy** to easily have a copy of an existing automation.

Copy a template

Use the **Copy Template** option to quickly duplicate existing templates and make similar updates, instead of building the template from the start.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.
A list of available templates and automation is displayed.
3. Mouse over the actions menu (vertical ellipsis) corresponding to the template that you want to copy.
4. Click the **Copy Template** icon.
 - a) In the **Copy file** window, enter a name for the duplicate template.

Note: The name must be unique if you want to create a copied template in the same folder location.

- b) Optional: Click **Browse** to select the folder where you want to save the template.
- c) Click **Copy**.

The duplicate template appears in the specified folder.

Delete a template

You can use the **Delete Template** option to delete templates that are not in use and to keep the private repository organized.

Before you delete a template, review the following prerequisites:

- Public workspace: You must have the Control Room administrator role or the **Delete from Public** permission at the folder level.
- Dependent folders and files: You must have the **Delete from Public** permission on these folders and files.
- Private workspace: You must have a Bot Creator or Citizen Developer license.

Important:

- You cannot delete a template if it is referenced by other templates or automations. You must first remove the references before deleting the template.
 - You cannot restore a deleted template, so ensure that you no longer require a template before deleting it.
-

Perform the following steps to delete a template from a private or public workspace.

- Delete templates from a private workspace

Note: In a private workspace, you can delete only templates that are in the **New** or **Cloned** status. You cannot delete a template in the **Checked out** or **Checked out and edited** status.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.
A list of available templates and automation is displayed.
3. Select the template. Mouse over the actions menu corresponding to the template that needs to be deleted and then click **Delete Template**.
4. Click **Yes, Delete**.

- Delete templates from a public workspace

Note: In the public workspace, you can delete only templates that are in the **Public** status. You cannot delete templates that are in the **Checked out** status.

1. Log in to the Control Room as an administrator, a Bot Creator, or a user with **Delete from Public** permission.
2. On the left pane, click **Automation**.

A list of available templates and automation is displayed.

3. Select the template. Mouse over the actions menu corresponding to the template that needs to be deleted and then click **Delete Template**.
4. Click **Yes, Delete**.

Check in a template

Check in templates to the public workspace from the private workspace to make them available for all users with permission to create and edit the templates.

Check-in of templates is essential so that Citizen Developer or other users can see all the available templates in the public repository and can use them to create automations.

- You must have a Bot Creator or Citizen Developer license to check in a template to the public workspace.
- You must be assigned a custom role with the following permissions:
 - **Check in** permission at the folder level and at the corresponding parent folder level in the public workspace.
 - To check in a template with dependent folders and files, you must have **Create folder** permission on the corresponding folders.

For example, if you are checking in a template from your private workspace and if the folder in which the template is present does not yet exist in the public workspace, you must have **Create folder** permission to successfully check in the template.

1. Log in to the Control Room.
2. On the left pane, click **Automation** and then select **Private**.
A list of available templates and automation is displayed.
3. Check in either one template or multiple templates simultaneously.
 - Check in single template
 - a) Select the template that you want to check in, click the actions menu (vertical ellipsis), and click **Check in Template**.
 - b) In the **Check in file** window, add your comment and click **Check in**.

Note: Directly referenced dependencies are checked in by default.

- Check in multiple templates

Note: You can check in up to 10 templates at a time.

- a) Select **Check all** or select the templates that you want to check in, and from the table level icons click **Check in checked items**.
- b) Add the comment and click **Check in**.
- c) Optional: Select **Advanced option**, add the comment, select the files you want to check in, and click **Check in**.

The template appears in the same folder structure in the public workspace. For example, when you check in a template from the sample template folder in the private workspace, it will appear in the sample template folder in the public workspace. Directly referenced dependencies are selected for check in by default. You can review and select other dependencies to check in.

Check out a template

Professional developer or Citizen Developer, you can check out templates from the public workspace to the private workspace to create an editable copy of the template in the private workspace and make further modifications based on changes in your business scenarios.

After you have modified the template, you can check in the template again to the public workspace so that it can be deployed by all users who have permission to access it. You can choose the specific version of the template along with their dependencies during the check-out process.

- You must have a Bot Creator or Citizen Developer license to check out a template to your private workspace.
- You must be assigned a custom role with the following permissions:
 - **Check out** permission at the folder level.
 - **Check out** permission on the dependency folders to check out a template with dependent folders and files.
 - To check out a template with dependent folders and files, you must have **Create folder** permission on the corresponding folders.

1. Log in to the Control Room.
2. On the left pane, click **Automation** and then select **Public**.
A list of available templates and automation is displayed.
3. Check out either one template or multiple templates simultaneously:
 - Check out single template
 - a) Select the template you want to check out, click the actions menu (vertical ellipsis), and click **Check out Template**.

Note: If a template has multiple versions, you can select and check out the specific version of the template using **Advanced** options. This enables you to roll back to an earlier version of the template.

- b) In the **Check out** window, choose any one of the following options:

Option	Steps
Yes, Check out	Select this option to check out the latest version of a template. The dependencies are cloned automatically.

Option	Steps
Advanced options	<p>Select this option to select a specific version of the template and dependencies.</p> <ol style="list-style-type: none"> 1. Click Advanced options. The Check out file window opens. 2. Version: Select the version of the template to check out, click the right arrow, and then Next. 3. Check out Dependencies: From the Available dependencies, choose the dependencies to check out, and then click Next. 4. Versions for dependencies: Select the version of the dependency to check out. 5. Review other dependencies: (Overwritten, Missing, Cloned, or Skipped). 6. Click Check out.

- Check out multiple templates
 - a)** Select the templates you want to check out and from the table level icons, click **Check out checked items**.
 - b)** In the **Check out** window, choose any one of the following options:

Option	Steps
Check out	<p>Select this option to check out the latest version of a template. The dependencies are cloned automatically</p>

Option	Steps
Advanced options	<p>Select this option to review the information about the template and dependencies which can be checked out, skipped, or cloned and then click Check out.</p> <ul style="list-style-type: none"> • The Files tab displays the available and selected files. You can add or remove files to check out. • The Checkout Dependencies tab displays the dependencies which you can choose to check out. • The Review dependencies tab displays information on the dependencies which are Overwritten, Missing, Cloned, or Skipped.

After you check out the template with its dependencies, it appears in the same folder structure in the private workspace. However, if you do not select the dependencies to be checked out, it will be cloned in your private repository.

Cancel template check out

You can cancel templates that were checked out and no longer need to be updated. You can use the **Cancel check out for Template** option either from the public or the private workspace.

You must have the **Cancel checkout** and **View content** permissions on a public workspace to cancel or undo a check out performed by a Bot Creator or Citizen Developer user.

You do not require the **Cancel checkout** permission to cancel the checked out template from a private workspace.

You can cancel the checked-out template from your private workspace. Similarly, you can cancel the checked-out templates from the public workspace to releases the template for another user who has access in the public workspace. When you cancel check out, the template status changes to **Public** in the public workspace. In the private workspace, the status changes to **New** if any edits are made to the template. If there are no changes, the template is replaced with a clone.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.
3. Select the template. Mouse over the actions menu corresponding to the template that needs to be canceled, and then click **Cancel check out for Template**.
4. Click **Yes, Cancel check out**.

View version history of template

The **View history** option enables you to view the history of changes that have occurred on a template. The history includes actions performed by the user during a specific date and time, along with check-in messages.

- You must have either the check-in or check-out permission.
- You can view the version history of the templates available in the public workspace.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.

A list of available templates and automations is displayed.

3. View the version history of templates in the following ways.
 - Select the template for which you want to view version history. Hover over the actions menu (vertical ellipsis) located to the right of the template name and click **View history**.
 - Click the template name. When the template opens in the Bot editor, click the vertical ellipsis at the top-right corner and select the **View history** option.

The **View history** window opens listing all the versions of the selected template in a sequence (latest revision on the top and the first revision is at the end). The information includes the version number, check-in message, checked-in date and time, and checked-in by username.

View template dependencies and references

You can view dependencies and references of a template in both public and private workspaces. The **View dependencies and references** option shows files added as scanned or manual to a template as its dependencies.

With this information, you can understand the impact of the change in a template, maintain better code and reusability, and prevent conflicts.

Ensure that you have the **View content** permission.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.

A list of available templates and automations is displayed.

3. Select **Public** or **Private** to view the dependencies and references of a template in the following ways:
 - Select the template for which you want to view dependencies. Hover over the actions menu (vertical ellipsis) located to the right of the template name and click **View dependencies and references**.
 - Click the template name. When the template opens, click the vertical ellipsis at the top-right corner and select **View dependencies and references**.
 - Toggle between the **Dependencies** and **References** tabs to view the immediate files (parent and child Task Bots or templates).
 - **Dependencies**: Displays the files that the templates depend on.

- **References:** Displays the files that depend on the template.

Import templates

You can import a template with their dependencies from one Control Room to another to make it publicly available to developers of multiple Control Room instances.

- Ensure that the following permissions are enabled to import templates:
 - **Import** bots permission
 - Manage package feature permissions
 - **Create folder** permission (if required)
 - **Check-in** to public workspace permission if you are importing to the public workspace.
- You must have a Bot Creator or Citizen Developer license to import templates either into the private workspace or public workspace.

You can import templates into the public workspace if you have the required permissions, regardless of your license.

- Ensure that the version of Control Room and templates in the source and target Control Room instances are same for import as well as export.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.
A list of available templates and automations is displayed.
3. Click **Manage bots > Import**.

Note: This option currently applies to both bots and templates.

4. Browse and select the required zip file that you want to import.
5. Select the private workspace or public workspace.
6. If the exported template or file is password-protected, enter the password when prompted.
You can get the password from the user who exported this template or file.
7. If some of the files that are being imported are already available in your Control Room, select one of the following options.
 - **Skip the bot or file (don't import it)**
 - **Overwrite the bot or file with the imported one**
8. Click the **Import bots** option.
9. After the import is complete, based on your source environment, navigate to the corresponding repository (private or public, based on your selection in Step 4) to find and use the imported template.

Export templates

You can export a template with their dependent files from one Control Room to another.

- Only templates within the public workspace can be exported. To export a template, check in the template into the public workspace.
- You must have **Export bots**, **View package**, and **Check in** or **Check out** permissions to the required folders.
- Ensure that you have the View content rights at the folder level from which you want to export the template.
- To export the templates from one Control Room to another, both Control Room instances must be the same version.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.
A list of available templates and automations is displayed.
3. In the public workspace, use one of the following options to export templates:
 - Click **Manage bots > Export**.
 - From the table level icons, select **Export bots**.

Note: These two options currently applies to both bots and templates.

- Click the actions menu (vertical ellipsis), and then click **Export Template**.

The selected template as well as the required dependencies are displayed.

4. Select the template you want to export.

Note: You can select only the latest version of the template to export. Currently, the production label is not supported.

5. Click the right arrow (→) to add your selection and then Click **Next**.
6. Select the dependencies of the templates.
7. Click **Next**.

All related packages are displayed.

8. Select the necessary packages associated with the template to export.
9. Optional: You can select **Exclude bot packages** check box to remove all packages from the export.
10. Enter the name in the **Export name** field.
11. Optional: Enter and confirm your password.

Adding a password enhances the security for your templates or file when exporting from one Control Room to another.

12. Click **Export bots and files**.

All selected templates are exported into a zip file.

If you have configured SMTP, an email is sent that contains a link to the zip file of the exported template. If you have not configured SMTP, perform the following steps to access the link to the zip file of the exported template:

- a) Navigate to **Activity > Historical**.

- b) Search and view the historical activity of the exported template.
- c) Click **Download exported zip file**.
A link to download the zip file is displayed.
- d) Use the link to download the zip file and save it to a location for importing it to another Control Room.

Note: If you are exporting a large size template or dependency, there might be a delay in the download of the export zip file from the **Activity > Historical**.

Templates- Known behavior

Review some of the known behavior when using the template feature.

The following limitations apply to templates:

- Automation 360 preshipped templates are currently not available to use. However, you can create and publish custom templates based on your business needs.
- You can create templates only from Task Bot. Creating templates from **Forms** and **Process Composer** are currently not supported.
- On the **Automation** page, when you select **Task Bot from Template** option, the **Create Task Bot from Template** window will display templates only after templates are published in the public workspace.
- When you create and save a template with empty properties, the error icon is not displayed, as the system allows you to save a template without adding any property value.
- **Run** and **Schedule** options do not apply to templates.
- When you export and import templates from one Control Room to another, the description of the templates is not retained.
- You cannot use the following capabilities in templates as they are not currently supported- Clone, Move, Setting production label, Compare versions, Code analysis, and Bot insight.

Bot editor for creating bots

The Bot editor enables users to create and edit bots on any device and from anywhere the user can access a web browser.

Overview

Because Automation 360 is web-based, there is no separate client to download. Access the Bot editor by logging in to Automation 360, navigating to **Automation** on the left panel, and then creating or opening a bot.

The Bot editor is a web-based environment and includes the following features:

- Universal Recorder to simplify capturing processes
- Search for a bot from the public workspace and your private workspace and add that bot to the current bot.

The location of the selected bot in the public and private workspaces is also displayed.

Note: An error occurs if you add a bot from a folder in the public workspace for which you do not have the **Clone** permission for that folder.

- Powerful bot code management
- Python and JavaScript actions support inline scripting without linking, with drag-and-drop integration
- Rich variable passing, with no cross-language mapping required

Bot editor

Use the Bot editor to create and edit any bot through a web browser, regardless of the device or location. When you create a bot or modify an existing bot, the Bot editor is displayed.

You can create a bot by using the following options:

- On the **Home** page, click **Create a bot**.
- On the **Automation** page, click **Create new > Bot** in the top-right corner.
-

In the **Files and folders** table, click **Create a bot** ().

You can modify a bot by using the following options:

- On the **Automation** page, select the bot to modify, click the actions menu (vertical ellipses) and click **Edit Task Bot**.
- Select and open the bot you want modify.

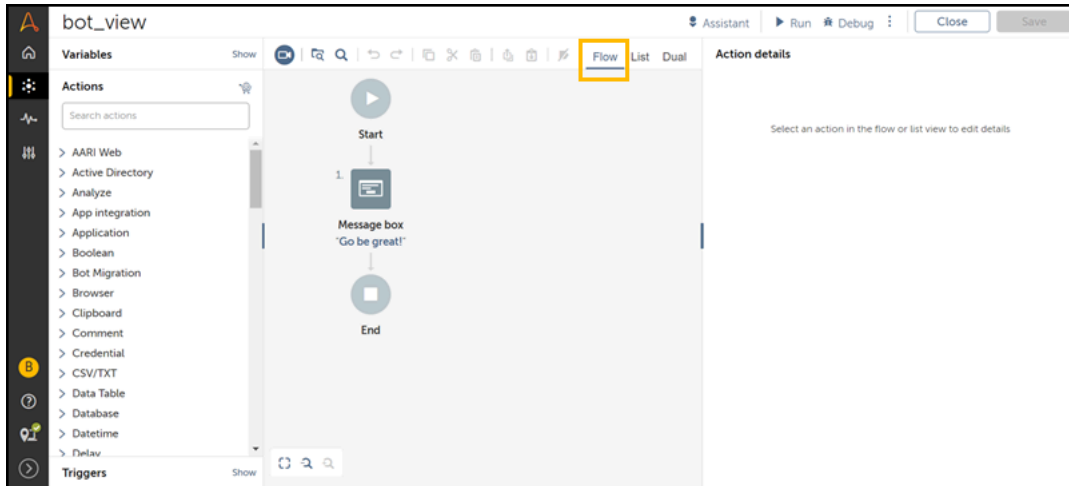

See also the video at the end of this page on how to get started with the Bot editor.

There are three view options for bot creation:

Note: You can use the search box in the **Flow**, **List**, or **Dual** view to search for text, variables, or actions in a bot. This feature can be helpful when you view or edit a bot with longer code lines.

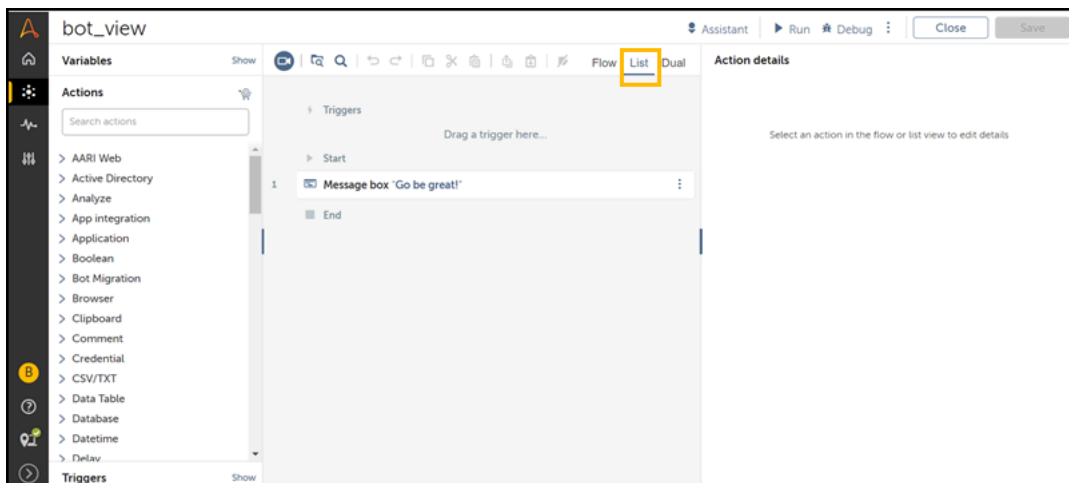

- **Flow:** Displays actions used in an automation as a flow diagram (Default)

Note: The **Flow** view is not available when you create or edit a bot and the bot exceeds 500 lines of code. Use the **Show list view** option to navigate to the list view.

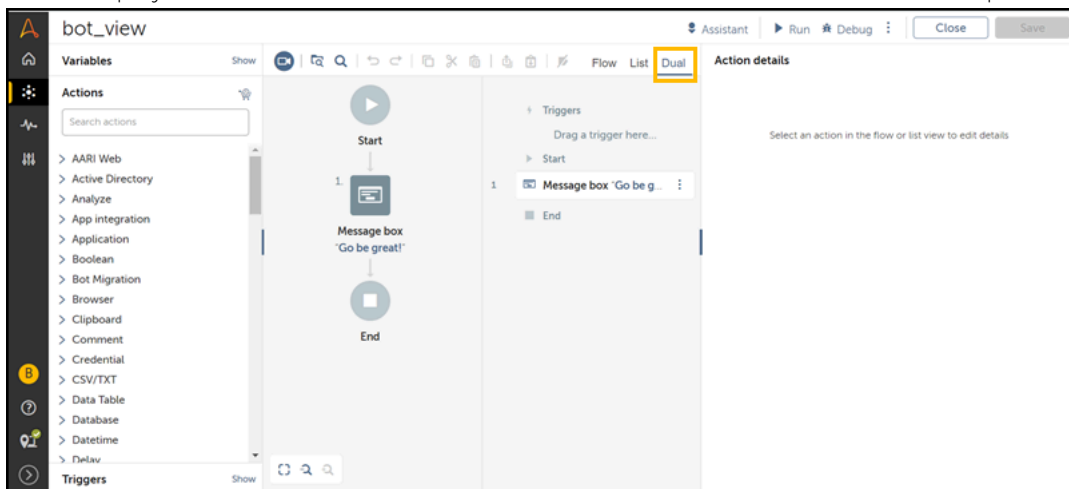

- **List:** Displays the actions used in an automation as a list

Note: Drag the selected actions within the task logic.

- **Dual:** Displays the actions used in an automation from both **Flow** and **List** view aspects

The **Flow**, **List**, and **Dual** views display the following properties of actions:

- The value that you enter for actions such as **Set text** for all the supported technologies
- Names of the objects on which actions such as **Set text**, **Click**, **Left click**, **Get property**, and **Select item by index** are performed
- Name of the object property mentioned in the action
- Name of the return variable if some value is assigned to a variable
- List of properties for the **Get property** action

See the video on enhanced bot building experience on Bot editor and AISense for Citizen developers.

Code analysis violations and policy details in Bot editor

Pro and Citizen Developers can see the code analysis violations in actions at the canvas level. A violation indicator is available for flow and list views, enabling Pro and Citizen Developers to quickly see and correct any actions in their automations that have code analysis violations. Code quality is enhanced when developers can easily determine violations and adhere to best practices when they are developing automations.

Pro and Citizen Developers no longer need to navigate to the policies page to view the applied policy and the rules contained in the policy. They can see the current code analysis policy and their rules from directly within the Bot editor from the drop-down menu (access from the three vertical ellipses in the upper right of the Bot editor) . This helps the users who do not have **View policies** and **Manage policies** permission to view current policy and their rules while editing the automation in the Bot editor itself instead of just viewing the violation.

Bot Assistant

When you create a bot, use the feature Bot Assistant to get a comprehensive view of line numbers of the bots that require your action.

The Bot Assistant displays the name of the packages or action and line number on which action is required by you. When you click the line number, it directly takes you to the line where the error occurs.

For migrated bots, the Bot Assistant displays a comprehensive view of the package or action and line numbers of the bots that require review or action by you.

Related tasks

[Edit a bot](#) on page 2222

Edit bot logic using the Bot editor to add, modify, or delete actions and automation steps.

[Run a bot](#) on page 2206

You can run a bot to test an automated process.

Using Bot editor

As a Bot Creator, you can build bots on the workbench and perform various bot operations. The Bot editor provides an easy to use feature-rich experience.

Default view in the Bot editor

We provide implicit preference to retain the default view, so you do not have to set them explicitly in the Bot editor. When you create or modify an existing bot in the Bot editor, your preferred default view (List, Flow, or Dual) will persist; and if you switch to another browser or log out and log back into the Control Room, you will see your default view. When you open a bot in the Bot editor, the default view is displayed as follows:

- If you open the bot for the first time, **Flow** view is shown as the default view. However, you need to change the view by selecting it based on your preference so that you can see the same view upon your subsequent login.
- For all subsequent visits to the Control Room, your last selected view will be set as the default view.

The set default view remains the same across browsers and user sessions.

Line markers for collapsible sections of code

When you create bots using **Loop**, **If/If-else**, **Step**, **Trigger-loop**, **Try**, **Catch**, and **Finally** statements, you will see the visually highlighted collapsible sections on the Bot editor. These visual indicator line markers are displayed at the beginning and end of the collapsible section. Additionally, when you select the collapsible section a line displays that connects the beginning and end brackets.

Note: The visual indicator line marker for the collapsible section applies only to the **List** view in the Bot editor.

Error messages with descriptive information

When you create a bot where the parent bot calls a child bot, and if an error occurs in the child bot, the error message displays the following details:

- Line number of the parent bot which ran the child bot.
- Line number of the child bot where the error occurred.
- Error message details, such as what went wrong with that line number and the corresponding corrective action.

The following example shows different error messages displayed during runtime:

- One parent bot calls two child bots.

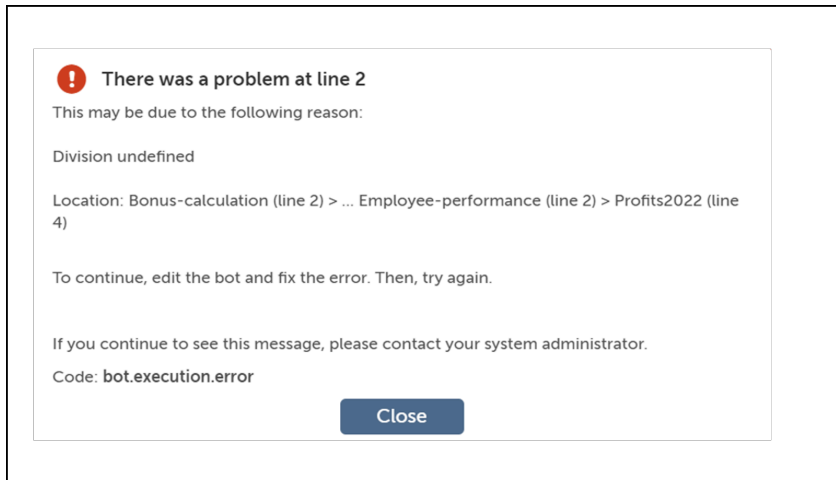

For example, you build a parent bot such as `Bonus calculation`. The parent bot calls the child bot `Company performance`, and then the child bot `Company performance` calls another child bot `Profits2022`. If the error is in the child bot `Profits2022`, the following error message will be displayed:

View the following video that outlines the sample error scenario

- One parent bot calls multiple child bots.

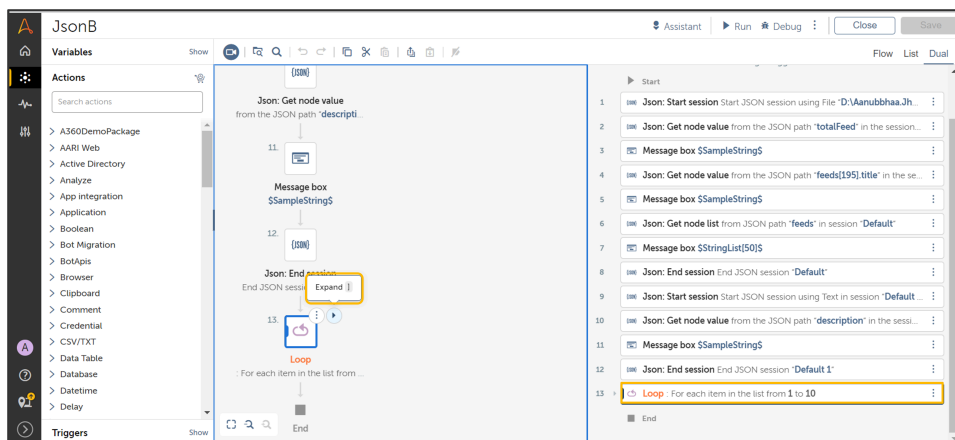

For example, you build a parent bot such as **Bonus calculation**. The parent bot calls the child bot **Company performance**, and then the child bot **Company performance** calls another child bot **Employee performance**. Then **Employee performance** calls **Completed targets > Profits2022**. If the error is in the child bot **Profits2022**, the following error message will be displayed:

Keyboard shortcuts to expand or collapse elements in bot logic

When you are creating a large bot, you can expand or collapse sections using keyboard shortcuts in both **Flow** and **List** views.

By using this feature, you can improve your productivity as a Bot Creator. It enables you to use keyboard shortcuts in a specific section or all sections, and you can move quickly through the process of developing a bot.

Shortcuts to expand or collapse an action is applicable only when the section is selected. You can use the following list of keyboard shortcuts in your bots.

Shortcut	Action
[Collapses the current node
Ctrl+[Collapses all the nodes
]	Expands the current node
Ctrl+]	Expands all the nodes
←	Collapses the current node or collapses to parent if already collapsed
→	Expands the current node

These keyboard shortcuts to expand and collapse nodes are supported in the following packages and actions:

- Loop package
- If package> **If**, **Else if**, and **Else** actions
- Error handler package> **Try**, **Catch**, and **Finally** actions
- Step package
- Trigger Loop package> **Trigger Loop** and **Handle** actions

Keyboard shortcuts list

Review the list of keyboard shortcuts that are supported.

All modes - Flow or List view

In the Bot editor, you can open a menu to display available keyboard shortcuts.

Keys	Action
Esc	Closes node details or clear cursor
Tab	Toggles Flow or List view
Enter	Shows node details and focus first input
Space	Toggles node details
Ctrl A	Selects all nodes

All modes - Flow view

Keys	Action
Up	Moves cursor up
Down	Moves cursor down
Left	Moves cursor left
Right	Moves cursor right

All modes - List view

Keys	Action
Up	Moves cursor up
Down	Moves cursor down

Edit mode

Keys	Action
Ctrl S	Saves file

Keys	Action
F5	Run
F10	Enters debug mode
Shift F9	Toggles all breakpoint

Edit modes - Flow or List view in focus

Keys	Action
Ctrl Shift R	Starts recording
Ctrl /	Enables or disables mode
F9	Toggles node breakpoint
Ctrl C	Copy node
Ctrl X	Cut node
Ctrl V	Paste node
Delete	Delete node
Ctrl Z	Undo
Ctrl Y	Redo

Debug mode

Keys	Action
F5	Play/pause/restart
F6	Step next
F7	Stop
F10	Exits debug mode
Shift F9	Toggles all breakpoints

Debug mode - Flow or List view in focus

Keys	Action
F9	Toggles node breakpoints

Node details

Keys	Action
Ctrl Enter	Accepts current input and saves the action or trigger

Get started with recorders

You can use two recorders in Automation 360, the Universal Recorder and the AISense Recorder, to automate tasks by recording interactions with objects such as click, read (data extraction), and write (data entry).

An integrated Recorder

In versions 2.0.9-20201105-164103 and later, the Recorder package contains both the Universal Recorder and AISense Recorder. This offers the following benefits:

- Feature updates are delivered as delta updates, which reduces the time spent downloading the newest Recorder package each release.
- The **Start recording** icon serves as a common entry point to both recorders.

Note: The AISense Recorder fails if you manually upgrade the Recorder package version, such as by importing a bot that contains the integrated Recorder package (Version A2019.17 and later) to a Control Room that has a build from Version A2019.16 or earlier. Always upgrade the Recorder package through the Control Room. Do not attempt to manually upgrade by importing a .jar file or bot.

Choosing which recorder to use for your task

Before you start building your bot, decide which recorder best fits your requirements.

Universal Recorder

Use Universal Recorder when you want to record interactions such as click, read, or write with user interface objects on your business application. After you have captured the object, you can specify your requirements in terms of the action to be performed on that object.

For example, if you capture a hyperlink, you can select an action to click the link or to retrieve the link text. Similarly, if you capture a table object, you can specify to either retrieve the total number of rows from a table object or retrieve each row one by one and perform any actions on it. This is the most reliable form of automation because it is performed on user interface objects rather than coordinates, images, keystrokes and so on.

AI Sense Recorder

Use AI Sense Recorder when you are building and automating your bots on applications that are exposed over Citrix or accessed over RDP. You can also reduce the time spent on building and automating your bots for legacy applications where object-based automation is difficult.

The recorder's resiliency to screen resolution, browsers, and user interface alterations reduces limitations and obstacles when recording tasks across your business applications.

Universal Recorder for object-based automation

Use the Universal Recorder to record interactions, such as click, read (data extraction), and write (data entry), with user interface (UI) objects on the desktop, taskbar, or in an application or browser window.

The earlier Automation Anywhere RPA products such as Version 11.3 have three separate recorders to capture objects from various environments. Automation 360 combines the capabilities of these three recorders into the Universal Recorder to streamline the recording process.

Using the Universal Recorder

You can use the Universal Recorder in the following ways:

1. To record a process consisting of multiple steps, use the Universal Recorder video camera icon, which is located on the top-left of the workbench.

Depending on where you want to add newly captured actions in an existing Task Bot, use one of the following ways:

- To add newly captured actions below an existing action, select the existing action and then start recording.
- To add newly captured actions before the existing actions that are available inside another action, select the other action and then start recording. For example, if you want to add newly captured actions before the existing actions that are available inside a loop action, select the loop action and then start recording.

Note: If you do not select any action, then the newly captured actions are added at the end of the Task Bot by default.

See [Record a task with the Universal Recorder](#) on page 2164.

2. To record a single interaction that you want to add into an existing Task Bot (for example, if you missed a step when recording a task), use Capture action from the Recorder package.

See [Using the Capture action](#) on page 2818.

For a common use case, see [Example of entering data into a web form from a spreadsheet](#) on page 3074.

The Universal Recorder is also used within actions to capture coordinates (**Mouse > Click** action) or a local file path (**Application > Open program/file** action).

Background processing

Background processing enables an automation that involves interacting with an application in the foreground (such as mouse clicks) to run in the background. We recommend that you use the option to run in background to increase the visibility of the target object and improve bot accuracy. The following actions support background processing:

- Click
- Set Text
- Get Text

Related tasks

[Record a task with the Universal Recorder](#) on page 2164

Use the Universal Recorder to capture a series of interactions (clicks, keystrokes, and mouse movements) with object controls including text boxes, buttons, tables, menus, radio buttons, combo boxes, check boxes, list views, links, trees, and page tabs.

[Edit a task recorded with the Universal Recorder](#) on page 2166

After recording a task, edit the **Capture** actions to change the window, capture a different object, select a new action, enable background processing, enter a different wait time, or save the output to a variable.

Related reference

[Browser requirements for Automation Workspace](#) on page 1154

Access the Automation Workspace interface from a browser. After you have installed and enabled extensions in the browser, perform several tasks through the Automation Workspace interface based on your user role and automation requirements.

[Secure recording mode](#) on page 2179

When secure recording mode is enabled, the bots do not capture values of certain properties or store application images. This ensures that sensitive data is not stored in the bots. This setting only applies to bots that are created or edited after the mode is enabled.

[Recording tasks in applications that run on JRE](#) on page 2180

Use the Universal Recorder to capture objects from Java applet, web start, and desktop applications that run using Java Runtime Environment (JRE) 6, 7, 8, 9, 10, and 11.

[Recorder package](#) on page 2798

Recorder package captures a series of tasks in a process and then automates them. You can automate your business applications (for example, desktop, Web, SAP, and Java applications) using the Recorder to capture actions performed on application objects such as a text box, button, table, radio button, combo box, and list view.

[Actions performed on objects captured with Universal Recorder](#) on page 2804

After capturing the object, specify the action for the bot to do to the object at runtime. For example, if you capture a hyperlink, you can select an action to click the link or to retrieve the link text. Refer to the table below for the objects and their possible actions.

Record a task with the Universal Recorder

Use the Universal Recorder to capture a series of interactions (clicks, keystrokes, and mouse movements) with object controls including text boxes, buttons, tables, menus, radio buttons, combo boxes, check boxes, list views, links, trees, and page tabs.

- To use the Recorder, you must already have done the following:
 - [Install Bot Agent and register device](#) on page 1288
 - [Set user device credentials](#) on page 1295
- Configure device display and font scale to 100%.

If you are using Recorder package version 2.0.6-20200626-193519 or later, you can record tasks in Google Chrome, Internet Explorer, Java, Microsoft Active Accessibility, and Microsoft UI automation applications on a computer that has display scale configured to 100%, 125%, or 150%.
- If you are automating a task using a browser, configure the zoom level to 100%.

If you are using Recorder package version 2.0.6-20200626-193519 or later, you can record tasks in a Google Chrome browser that does not have a zoom level setting of 100%.
- If you are automating a task using a Google Chrome browser, ensure that the Automation Anywhere plug-in that corresponds with the Automation 360 build version is enabled.

[Browser requirements for Automation Workspace](#) on page 1154
- To automate web applications running on Microsoft Edge Chromium browser in Internet Explorer mode using the Universal Recorder, ensure that the Internet Explorer compatibility mode is enabled. The objects on the web applications are captured using HTML technology. To enable this mode, perform the following steps:
 1. On the Microsoft Edge Chromium browser page, click **Settings**.
 2. On the left panel, click **Default browser**.
 3. Navigate to the **Allow sites to be reloaded in Internet Explorer mode** option and select **Allow**.
 4. Click **Add** to add the URL of the page that you want to load in Internet Explorer mode.

Note: The pages that you add open in Internet Explorer mode for 30 days from the date when you add the page.

Considerations when recording a task:

- Use clicks when possible rather than shortcut keys.

When you click an object using the Recorder, it retrieves the object's properties that enable the bot to identify the object at runtime. Keyboard shortcuts are less reliable, so use them when it is not possible to automate the task by a clicking an object.
- If you are automating a task using a browser, do not use autofill to enter values into fields.
- Record the task at low speed.
- Avoid dragging windows during the recording process.
- Avoid clicking on applications that are not part of the process you are recording and automating.
- When Internet Explorer is used, the action waits until the browser is completely rendered and is in a ready state before executing the action.

To record a task using the Universal Recorder, follow these steps:

1. From Automation Anywhere web interface left panel, click **Automation**.
2. Create a new bot or open an existing bot for which you want to record a task.
3. Click **Start recording**.

Note: In versions 2.0.9-20201105-164103 and later, the Recorder package contains both the Universal Recorder and AISense Recorder.

[An integrated Recorder](#) on page 2162

The **Automation Anywhere Recorder** window appears.

4. Select a window from the drop-down list.
If you opened an application recently and it is not available in the list, click the **Refresh** icon.
5. Click Universal Recorder .
6. Perform the steps in the task. For example, click buttons, fill in forms, or search a website.
To perform an action on an object, move the mouse pointer on that object. The object is highlighted with a box. If the box does not appear, verify that you have enabled the necessary plug-in. For more information, see [Universal Recorder supported applications and browsers](#) on page 2172.

The **Recorder** window contains the number of operations recorded and a description of the most recently captured object. For example, 5. Left click on button 'Submit'.

To redo the previous object capture, click the **Delete** icon at the bottom right of the **Recorder** window to discard the most recent capture.

If Secure recording mode is enabled, a shield icon appears to the right of the red recording icon.

[Secure recording mode](#) on page 2179

7. Click **Finish** after you finish capturing all the necessary objects.
A **Capture** action is generated for each operation.
Where applicable, the **Recorder** generates variables. [Your variables \(user-defined\)](#) on page 2241
8. Edit the actions or click **Save**.
[Edit a task recorded with the Universal Recorder](#) on page 2166

Edit a task recorded with the Universal Recorder

After recording a task, edit the **Capture** actions to change the window, capture a different object, select a new action, enable background processing, enter a different wait time, or save the output to a variable.

Select the **List** view to see the full details of each action.

Edit a recorded task to do the following:

- Change the application window in which you want to perform the operation, or add a wildcard to the window title.
- Change the properties of the captured objects.
- Specify the action you want to perform on the captured objects.
- Introduce a delay before the next action is performed.
- Specify the variable you want to use to store the output.

To add a **Capture** action to the task, see [Using the Capture action](#) on page 2818.

To edit a recorded task, perform the following steps:

1. Open the bot that contains the recorded actions you want to edit.

2. Click the **Capture** action that you want to edit.

Make the following changes, as necessary:

3. Change the window selection to the **Currently active** window option.
4. Optional: Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value.

For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `(\w*)-Notepad` for all window title names starting with `(\w*)-Notepad`, or use **Pattern** value as `(\w)\s*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

Note: During runtime, verify that the Task Bot identifies the correct window. If it does not, do the following:

- a) Open the application or browser window.
- b) Drag a **Window > Get active window title** action above the **Recorder > Capture** action.
- c) Insert a string variable into the **Assign the window title to variable** field.
- d) Drag a **Window > Set title** action below the **Window > Get active window title** action.
- e) In the **Window** field, insert the window variable generated by the **Recorder > Capture** action.
- f) In the **New window title** field, insert the string variable from the **Get active window title** action.

g) Click **Save**.

5. Optional: Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.

- If the window is maximized when you record the task, this option is not selected.
- If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

6. Review the **Object properties** table.

Following are the list of object properties that are selected by default based on the technology type:

Important: The following list does not include all the properties and is restricted to the most commonly used and important properties based on the technology type

Technology type	Object properties	Description
HTML Technology	Control type	This is a read-only property that shows the type of object captured, for example, text box or button.

Technology type	Object properties	Description
	DOMXPath	<p>It is the path that is used to locate the control or object that is captured.</p> <p>DOMXPath can be of two types: Relative XPath and Absolute XPath.</p> <ul style="list-style-type: none"> • Absolute Xpath: It contains the complete path from the root element to the desired element. For example, an absolute Xpath for this topic would be <code>/html/body/div/div[1]/main/div[2]/div/div/div[2]/div/div/div[1]/div/article/main/article/div/p[1]</code> • Relative Xpath: This is a shorter path that refers to an element you want to identify. A relative path starts with a <code>//</code> symbol. For example, the relative XPath for this topic would be <code>//*[@id="cloud-using-recorder-action"]/div/p[1]</code> <p>For example, if you want to find the DOMXPath of a particular element on Google Chrome browser, perform these steps:</p> <ol style="list-style-type: none"> a) Select the element for which you want to extract the XPath. b) Right-click the element and select Inspect. c) Right-click the highlighted element in the Element tab. d) Go to Copy > Copy XPath to copy the relative path and select Copy > Copy full XPath to copy the absolute path.
	Path	<p>It is a numeric representation of the position of a particular control in an application. For web applications, the best practise is to use DOMXPath from the search criteria when compared to Path.</p>
	HTML name and ID	<p>These properties are used to identify an HTML object</p>
	HTML inner text	<p>The DOM innerText Property is used to set or return the text content of a specified node and its descendants</p>

Technology type	Object properties	Description
	HTML tag	HTML tags are like keywords that define the way web browser formats and displays the content. For example, if the captured text has an HTML code: <code><h3 class="search_results-title">Search results for "string package"</h3></code> , then enter h3 in the HTML tag field.
Microsoft Active Accessibility	Control type	This property is used only as a reference to ensure that the correct object is captured
	Path	It is a numeric representation of the position of a particular control in an application
	Name	This specifies a name of an element and works as an identifier
	ID	This specifies the ID of an element and works as an identifier
Java Technology	Control type	This property is used only as a reference to ensure that the correct object is captured
	Path	It is a numeric representation of the position of a particular control in an application
Microsoft UI Automation	Control type	This property is used only as a reference to ensure that the correct object is captured
	Path	It is a numeric representation of the position of a particular control in an application
	Name	This specifies a name of an element and works as an identifier
	ID	This specifies the ID of an element and works as an identifier
	IsFirst	This property enables the bot to detect the first object based on your search criteria instead of traversing the entire tree. You can use this property when an object does not have a unique Automation ID and the object hierarchy changes in the application.
Microsoft UI Automation (COM)	Control type	This property is used only as a reference to ensure that the correct object is captured.
	Path	It is a numeric representation of the position of a particular control in an application.
	Name	This specifies a name of an element and works as an identifier.
	ID	This specifies the ID of an element and works as an identifier.

The bot uses the selected properties to identify the object control at runtime.

- a)** Verify that the **Control Type** matches your intended object.

For example, when capturing a table from a website, ensure the **Control Type** and **HTML Tag** values are **Table**.

If the **Control Type** does not match your intended object, recapture the object control.

- b)** Select and assign values to the object properties that you want to include in the object search.

For a more reliable bot, we recommend that you select only the properties that have static values (such as **Name**, **Class**, **Type**, **HTML ID**, and **DOMXPath**), and deselect the properties that have dynamic values (such as **HTML Href**, **Path** or **Value**), which are subject to change and cause bot errors.

It is a best practice to use the wildcard character (*) or variable in object property values to search for objects whose properties are dynamic and changes frequently.

- 7.** Select the **Action** from the drop-down list.

For a full list of possible actions by object, see [Actions performed on objects captured with Universal Recorder](#) on page 2804.

- If you record a click and keystrokes in a text box with a **Control Type** of `Password text`, the **Recorder** does not capture the keystrokes entered into the field. Instead, the action selects the **Set text** option and offers options to securely input the password. We recommend that you store the password in the Credential Vault and insert it into the action as a credential. [Credentials and credential variables in the Bot editor](#) on page 2254

If you navigate to the text box using the TAB keystroke instead of a click in an MSAA or SAP application, the **Recorder** is able to identify fields with a **Control Type** of `Password text`.

We recommend that you use the **Set text** action without setting a delay time to enter keystrokes into a text field. However, if the text that you want to enter consists of a control key value or a text field requires any key press event, then you must set a delay time between the keystrokes when using the **Set text** action.

- If the selected **Action** supports background processing, a **Run in the background** option appears. [Background processing](#) on page 2164

- 8.** Optional: Enter a value in the **Wait for control** field to specify the number of seconds the bot must wait for the object control to appear on the application window.

- 9.** Optional: Assign the output to a variable.

The Control Room suggests a descriptive default variable name based on the action you selected in step 8. For example, if you selected **Get property**, the suggested output variable is `PropertyValue`. If you create several output variables, subsequent variable names are appended with a -1 to avoid duplication.

- 10.** Perform the Steps 3 through 9 for the other actions that you want to edit in the bot.

- 11.** Click **Save**.

Link an object to a supporting anchor

Note: You can use object anchoring in Microsoft Active Accessibility, Microsoft UI Automation, or Java applications.

At runtime, if the bot cannot reliably identify an object, link it to a nearby object (such as a link or button) that is easier for the bot to find:

1. Open the **Capture** action.
2. Click the **Anchor** tab.
3. Click **Capture anchor**.

The browser or application window activates with the main object highlighted (the object that you previously captured). A dialog box appears, verifying whether the action has correctly identified the main object.

4. If the correct object is highlighted, click **Yes, Select anchor**.
Otherwise, click **No, I need to correct it** to select the correct object.
5. Select a nearby object to the target object that is easier for the bot to find.
The object is highlighted with an anchor icon on the right of the object.
6. Click **Save**.

Universal Recorder supported applications and browsers

Use the Universal Recorder to record interactions with objects from the supported technologies.

Applications

- HTML applications
- Java applet, web start, and desktop applications that run using Java Runtime Environment (JRE) 6, 7, 8, 9, 10, and 11 (32-bit and 64-bit versions)

See [Recording tasks in applications that run on JRE](#) on page 2180.
- Microsoft Active Accessibility and UI automation
- Microsoft Silverlight version 5 (standard Microsoft controls only)
- Oracle EBS and Forms
- SAP versions 730, 740, 750 patch 9, 760 patch 5, and 770 patch 6
- Citrix Virtual Apps
- Electron

Technologies

- Microsoft Active Accessibility (MSAA)
- Microsoft UI automation

Note:

Silverlight technology is supported for migrated bots only. You can migrate any Enterprise 11 bots that you created using Silverlight technology to Automation 360. To modify the migrated bots or create new bots to automate Silverlight web applications, you can capture the web application using Microsoft UI Automation technology. Microsoft UI

automation supports only standard controls for a Silverlight application.

Browsers

- Google Chrome (versions 91 and later) for Manifest V3 extension
- Google Chrome (versions 90 and earlier) for Manifest V2 extension

To build and run bots that contain actions from the Recorder package, you must enable the Google Chrome extension that corresponds with the Recorder package version. See [Google Chrome browser extension requirements](#) on page 2174.

If you encounter an error when recording or running a bot that automates tasks in a Google Chrome browser and you have installed Google Chrome, you must perform additional steps to configure your system. See [Google Chrome extension troubleshooting](#) on page 2175.

- Internet Explorer (version 11)
- Microsoft Edge (version 91 and later) for Manifest V3 extension
- Microsoft Edge (version 90 and earlier) for Manifest V2 extension
- Microsoft Edge based on Chromium (versions 79 and later)

Microsoft Edge is supported on Recorder package version 2.0.9-20201105-164103 and later. You must install the A2019 plugin for Microsoft Edge and verify that it is running in the Task Manager: [Automation 360 extension for Microsoft Edge](#)

Note: Ensure that the Google Chrome extension is not installed in the Microsoft Edge browser because that configuration causes recording and runtime errors. [Google Chrome extension installed in Microsoft Edge](#) on page 2178

- Mozilla Firefox (versions 80 and later)

Mozilla Firefox is supported on Recorder package version 2.0.11-20210128-034104 and later. You must install the A2019 extension for Mozilla Firefox: [Automation 360 extension for Mozilla Firefox](#)

Desktop	The desktop refers to the device screen when all application and browser windows are minimized.
Taskbar	The taskbar is the horizontal or vertical bar containing icons of open applications and browsers, as well as the notification area. You can capture application, browser, and system icons, such as Clock and Calendar, volume, and Wi-Fi.
UI objects	See Actions performed on objects captured with Universal Recorder on page 2804.

Related reference

[Actions performed on objects captured with Universal Recorder](#) on page 2804

After capturing the object, specify the action for the bot to do to the object at runtime. For example, if you capture a hyperlink, you can select an action to click the link or to retrieve the link text. Refer to the table below for the objects and their possible actions.

Google Chrome browser extension requirements

Ensure the Automation Anywhere Google Chrome extension you are using corresponds with the Recorder package version in your bots.

Automation Anywhere has created two versions of the Google Chrome extension, based on the Recorder package version. Automation Anywhere A2019 extension version 1.1.0.1 is the recommended Google Chrome extension for bots that contain actions from the Recorder package 2.0.6 and later. Automation Anywhere Google Chrome extension version 11 or 12 is required only to run bots that contain actions from the Recorder package 2.0.5 and earlier.

Use the table below to verify that your system is running the correct browser agent and Google Chrome extension.

- Verify the browser agent in the **Windows Task Manager > Details** tab.
If the browser agent is in the Task Manager, but is not running:
 1. Verify that the ComSpec variable is defined in the **Environment Variables** list.
You can locate this list in **My computer > Properties > Advance System Settings > Environment Variables**.
 2. If the ComSpec variable is not in the list, define it by specifying the **Variable Name** as ComSpec and the **Variable Value** as %SystemRoot%\system32\cmd.exe.
- Verify the Google Chrome extension version in `chrome://extensions/`.
- If necessary, install the Google Chrome extension using the links in the table below.

Google Chrome re-verification: Google Chrome requires re-verification of permissions when the Automation Anywhere Google Chrome extension is updated. If prompted, click **Enable this item** in the Google Chrome message. Alternatively, re-enable the extension through the links in the table above. Similarly, if you are deploying your Bot Runners from a master image, accept the permission from within that image.

Recorder package version	Browser agent	Google Chrome extension and ID
2.0.5 or earlier	Automation.BrowserAgent.exe	Version 11 or 12 ID: jjpdebaihkanqkfpbgfmmnlafkahebn
2.0.6 or later	Automation.Bot.BrowserAgent.exe	Version 1.1.0.1 or later ID: kammdlphdfejllopponbapggpbgakimokm

Note: If you upgrade the Bot Agent version by uninstalling the Bot Agent instead of directly upgrading, this also uninstalls the Google Chrome extension. In that case, you must manually reinstall the Google Chrome extension.

If you encounter an error when recording or running a bot that automates tasks in a Google Chrome browser and you have installed the Google Chrome, you must perform additional steps to configure your system. See [Google Chrome extension troubleshooting](#) on page 2175.

Related reference

[Google Chrome extension troubleshooting](#) on page 2175

If you encounter an error when recording or running a bot that automates tasks in a Google Chrome browser and you have installed Google Chrome, you must perform additional steps to configure your system.

[Google Chrome extension troubleshooting](#)

If you encounter an error when recording or running a bot that automates tasks in a Google Chrome browser and you have installed Google Chrome, you must perform additional steps to configure your system.

Prerequisites

Ensure the Automation Anywhere Google Chrome extension you are using corresponds with the Recorder package version in your bots. See [Google Chrome browser extension requirements](#) on page 2174.

To configure your system to run the Google Chrome extension, choose the scenario that applies to you and follow the steps.

Recorder package version 2.0.9 or later:

1. Verify that Google Chrome extension version 1.1.0.1 or higher is installed and enabled.
To install the extension, see [Version 1.1.0.1 or later](#).
2. Open the Windows registry to the Google Chrome browser agent: Computer
`\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Google\Chrome`
`\NativeMessagingHosts\automation.bot.browseragent`
3. Verify that the registry entry points to the Automation 360 Bot Agent installation directory:
`C:\Program Files\Automation Anywhere\Bot Agent\AABrowserAgent`
`\AAChromeAgentManifest.json`

If this configuration is missing, reinstall the Bot Agent.

Recorder package version 2.0.6, 2.0.7, or 2.0.8 (for Version A2019.16 or earlier)

1. Open the Windows registry to the Google Chrome browser agent: `Computer\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Google\Chrome\NativeMessagingHosts\automation.chrome.agent`
2. Verify that the registry entry points to the Automation 360 global cache: `C:\ProgramData\AutomationAnywhere\GlobalCache\embedded-resources\<Recorder package version>\AAChromeAgentManifest.json`

For example, `C:\ProgramData\AutomationAnywhere\GlobalCache\embedded-resources\2.0.6-20200626-193519-1bd6fceb-b036-4202-9932-4dc18349bd5c\AAChromeAgentManifest.json`

If this configuration is missing, do the following steps as an admin:

- a) Open the Automation 360 global cache: `C:\ProgramData\AutomationAnywhere\GlobalCache\embedded-resources\<Recorder package version>`
- b) Run the `install.ps1` file.
- c) Repeat steps 2 and 3 to verify the registry entry is updated.

Recorder package version 2.0.5 or earlier, and never installed Automation Anywhere Enterprise Version 11.3 or later

Note: Use latest Recorder package version available in your Control Room.

1. Verify that Google Chrome extension version 11 or 12 is installed and enabled.
To install the extension, see [Version 11 or 12](#).
2. Open the Windows registry to the Google Chrome browser agent:
`Computer\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Google\Chrome\NativeMessagingHosts\automation.chrome.agent`
3. Verify that the registry entry points to the Automation 360 global cache: `C:\ProgramData\AutomationAnywhere\GlobalCache\embedded-resources\<Recorder package version>\AAChromeAgentManifest.json`

For example, `C:\ProgramData\AutomationAnywhere\GlobalCache\embedded-resources\2.0.5-20200626-193519-1bd6fceb-b036-4202-9932-4dc18349bd5c\AAChromeAgentManifest.json`

If this configuration is missing, do the following steps as an admin:

- a) Open the Automation 360 global cache: `C:\ProgramData\AutomationAnywhere\GlobalCache\embedded-resources\<Recorder package version>`
- b) Run the `install.ps1` file.

- c) Repeat steps 2 and 3 to verify the registry entry is updated.
4. Verify that the browser agent `Automation.BrowserAgent.exe` is running with the Google Chrome extension installed and enabled.
If this configuration is missing, restart Google Chrome. Either disable and enable the Google Chrome extension, or close all Google Chrome browser tabs and reopen a new window.

Recorder package version 2.0.5 or earlier, and installed Automation Anywhere Enterprise Version 11.3 or later

1. Verify that Google Chrome extension version 11 or 12 is installed and enabled.
To install the extension, see [Version 11 or 12](#).
2. Open the Windows registry to the Google Chrome browser agent: `Computer\HKEY_CURRENT_USER\Software\Google\Chrome\NativeMessagingHosts\automation.chrome.agent`
 - If the above key is available, disable the Google Chrome plug-in version 11.x and enable the Google Chrome plug-in version 12.x.
 - If the above key is not available, disable the Google Chrome plug-in version 12.x and enable the Google Chrome plug-in version 11.x.
3. Restart Google Chrome. Either disable and enable the Google Chrome extension, or close all Google Chrome browser tabs and reopen a new window.
4. Verify that the browser agent `Automation.BrowserAgent.exe` is running with the Google Chrome extension installed and enabled.

Automation Anywhere Enterprise Version 11.3 or later is uninstalled

Uninstalling the Enterprise Client does not remove the Google Chrome extension and registry entries. To remove them manually, do these steps:

1. Disable Google Chrome extension 12.x.
2. Install and enable Google Chrome extension 11.x.
3. In the Windows registry editor, remove the following key: `Computer\HKEY_CURRENT_USER\Software\Google\Chrome\NativeMessagingHosts\automation.chrome.agent`
4. Open the Windows registry to the Google Chrome browser agent:
`Computer\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Google\Chrome\NativeMessagingHosts\automation.chrome.agent`
5. Verify that the registry entry points to the Automation 360 global cache: `C:\ProgramData\AutomationAnywhere\GlobalCache\embedded-resources\<Recorder package version>\AAChromeAgentManifest.json`
For example, `C:\ProgramData\AutomationAnywhere\GlobalCache\embedded-resources\2.0.6-20200626-193519-1bd6fceb-b036-4202-9932-4dc18349bd5c\AAChromeAgentManifest.json`

6. Restart Google Chrome. Either disable and enable the Google Chrome extension, or close all Google Chrome browser tabs and reopen a new window.

Google Chrome extension installed in Microsoft Edge

Although Microsoft Edge browser settings allow extensions from the Chrome Web Store, we recommend that you do not install the Google Chrome extension in the Microsoft Edge browser. Installing it causes recording and runtime errors in bots that interact with the Google Chrome browser. Even if you did not manually install the Google Chrome extension, the auto-sync settings in the Microsoft Edge browser might have automatically installed the extension.

Unable to view Google Chrome extension in offline mode

1. Drag the file `ChromeExtension.crx` to the Google Chrome extension tab.
This file is available in the same path where the `Automation.BrowserAgent.exe` file is available.
Enable the Automation 360 Google Chrome extension.
2. If the Google Chrome extension is still not visible:
 - a) Verify if the registry entry `automation.chrome.agent` is available in the path `Computer\HKEY_CURRENT_USER`.
If it is not available, create the registry in the following path: `Computer\HKEY_CURRENT_USER\Software\Google\Chrome\NativeMessagingHosts\automation.chrome.agent`
This entry should have the same path as the entry: `Computer\HKEY_LOCAL_MACHINE\Software\Google\Chrome\NativeMessagingHosts\automation.chrome.agent`
 - b) Go to the path `Computer\HKEY_LOCAL_MACHINE\Software\Google\Chrome\Extensions`.
For the 11.1.0.0 Automation 360 Google Chrome extension ID `jjpdebaihkangkfpbgefmmn1afkaebn`, create a new string with the name `path`.
The value of the string will be the path of the `ChromeExtension.crx`, which is available in the same folder where the `AAChromeAgentManifest.json` file is available.
For example, add the entry `C:\ProgramData\AutomationAnywhere\GlobalCache\embedded-resources\2.0.5-20200511-172840-1825fd43-19bc-4dd2-ac56-53a2aed4b0e4\ChromeExtension.crx` in the following locations:
 - `Computer\HKEY_LOCAL_MACHINE\Software\Google\Chrome\Extensions (ExtensionID)`
 - `Computer\HKEY_CURRENT_USER\Software\Google\Chrome\Extensions (ExtensionID)`
 - c) Restart Google Chrome. Either disable and enable the Google Chrome extension, or close all Google Chrome browser tabs and reopen a new window.

Secure recording mode

When secure recording mode is enabled, the bots do not capture values of certain properties or store application images. This ensures that sensitive data is not stored in the bots. This setting only applies to bots that are created or edited after the mode is enabled.

A user with admin privileges must enable secure recording mode. See [Settings](#) on page 1728.

To capture objects in secure recording mode, ensure that the Recorder package is set to 2.0.0-20200318-020414 or higher. See [Manage Control Room packages](#) on page 1847.

When you record a task in secure recording mode, the **Preview** window temporarily shows the captured area. This image is deleted after you close the bot.

When you record a task in secure recording mode, you can choose whether or not the captured images are available for preview and stored in the Control Room. See [Secure recording](#) on page 990

Note: Ensure that you use the latest version of the Recorder package. If you are using the 2.7.3-20220527-004608 or an older version of the Recorder package, a preview of the images will be shown in the Bot editor when the objects are captured. The images will be discarded when you refresh the Bot editor.

You can update the following object properties after capturing an object:

Technology	Object property
Microsoft Active Accessibility/UI automation/Java	<ul style="list-style-type: none"> Item name Item value Name Parent Value
HTML	<ul style="list-style-type: none"> HTML InnerText HTML name HTML value
Microsoft UI Automation (COM)	<ul style="list-style-type: none"> Description Image Value Name Parent Item name Item value Data provider Content Legacy name Legacy value Legacy description

Recording tasks in applications that run on JRE

Use the Universal Recorder to capture objects from Java applet, web start, and desktop applications that run using Java Runtime Environment (JRE) 6, 7, 8, 9, 10, and 11.

Automation 360 supports JRE 6 and later on both 32-bit and 64-bit systems.

Verify whether additional configuration is necessary, depending on the JRE version:

- If JRE 7 update 6 or later is installed on the registered device, Java Access Bridge is automatically installed on that device.
- If JRE 7 update 5 or earlier is installed on the registered device, you must manually copy the required files to the corresponding directories. See [Java Access Bridge](#).
- If you have more than one version of JRE, Automation 360 configures Java Access Bridge with the default version. To configure it to a different version, you must manually copy the required files to the corresponding directories. See [Java Access Bridge](#).

The first time you record a task in an application running on JRE 6 or 7 update 5 or earlier, an error message might appear if the application is launched before Java Access Bridge is installed. Restart the application and proceed with recording the task.

AI Sense for recording tasks from remote applications

AI Sense is the artificial intelligence (AI) powered capability of Automation 360 that helps you identify objects from an image or an application with a complex user interface (UI) and make automation in all environments faster and more accurate.

AI Sense is suitable when object-based automation fails or is not efficient for automating tasks on applications that are accessed remotely, in a Citrix environment, and legacy applications.

Some of the issues that affect the accuracy of an automation task in a remote environment are as follows:

- In a Citrix environment, the automation platform receives an image of the application and does not have access to the actual UI elements.
- Screen resolution and scaling might not be the same on the host and client machines.
- The position of a UI element might change for web applications due to a different resolution on the Bot Runner machine.

AI Sense uses computer vision to intelligently create dynamic linking between objects by determining their composition to deliver change-resilient automation. AI Sense enables you to accurately automate applications even when labels and text change their position.

Important:

- Bots will fail if they contain actions from Recorder package versions 2.0.9-20201105-164103 or later and the AI Sense package. You must delete the **AI Sense** actions and recapture the objects using the integrated recorder icon. [An integrated Recorder](#) on page 2162
- AI Sense Recorder supports the following languages: English, Simplified Chinese, Korean, Brazilian-Portuguese, Japanese, and Russian. When you record an application, ensure that the device locale is set to the same language as that of the application, regardless of operation system and keyboard layout. If the user interface (UI) of the application is a combination of English and another language, set the device locale to the other language. For example, if the UI is a combination of English and Russian, set the device locale to Russian.

Note: Even if the device locale is set to a language other than English, you can continue to automate applications that have an English UI without changing the device locale to English.

Recommendation: On any application, regardless of the language of the application, when you use the **Get text** action to retrieve text from a specified area, if the retrieved text is not accurate, we recommend that you perform one of the following actions and then record again:

- Increase the font size.
 - Decrease the screen resolution.
 - Zoom in to capture the text correctly.
-

Related tasks

[Record a task with AISense Recorder](#) on page 2181

Use the AISense Recorder to record an end-to-end task on a remote application or an application with a complex user interface (UI).

[Edit a task recorded using AISense](#) on page 2183

After you have recorded a task using the AISense Recorder, you can edit the recorded actions to perform various actions on the captured objects.

Record a task with AISense Recorder

Use the AISense Recorder to record an end-to-end task on a remote application or an application with a complex user interface (UI).

- If you are automating a task using a browser, ensure that auto-fill is disabled for that browser.
- The screen resolution must be set to 1980x1080 or lower.
- Configure the device display settings to 100% DPI.
- If you are using Automation 360 On-Premises, ensure that the AISense Recorder package is added to your Control Room.

AISense Recorder can capture the following objects from an application: text boxes, buttons, radio buttons, combo boxes, check boxes, active and passive text, image button, scroll, and combo box.

Keep the following considerations in mind when recording a task:

- Record the task at low speed.
- Avoid dragging windows during the recording process.
- Avoid clicking applications that are not part of the process you are recording to automate.

To record a task using the AISense Recorder, follow these steps:

1. From Automation Anywhere web interface left panel, click **Automation**.
2. Create a new bot or open an existing bot for which you want to record a task.
3. Click **Start recording**.

Note: In versions 2.0.9-20201105-164103 and later, the Recorder package contains both the Universal Recorder and AISense Recorder.

[An integrated Recorder](#) on page 2162

The **Automation Anywhere Recorder** window appears.

4. Select a window from the drop-down list.

If you opened an application recently and it is not available in the list, click the **Refresh** icon.

5. Click **AI Sense Recorder**.

The first time you use the AI Sense Recorder on a device, the Recorder downloads the required dependencies.

The **Recorder** toolbar appears with **Finish**, **Scan**, **Define**, and **Pause** options.

The Recorder analyzes the application window you selected to identify the UI objects in that window. The options on the toolbar are disabled when the system is analyzing the application window. After the analysis, the options are enabled and you can start recording the task.

6. Perform the actions to record. For example, click buttons, fill in forms, or select an option.

To perform an action on an object, move the mouse pointer on that object. The system highlights an object along with the text associated with that object. For example, when you move the mouse pointer over a button or check box, the associated text with that button or check box is also highlighted and captured.

- If the object is not highlighted, click the **Scan** option on the recording toolbar. After the system finishes analyzing the application window, you can capture the required object.
- If you want to capture an option from a list, click the list and wait until the highlight appears around the box containing the options. After the box is highlighted, move the mouse pointer over the option you want to capture and wait until the option is highlighted.
- If you use scroll on an application window, you must click **Scan** to analyze the new objects on the window.
- If you want to record an interaction with an object that is only visible when you hover the mouse over the object, see [Detect hidden objects manually](#)

The **Recorder** window contains the number of operations recorded and a description of the most recently captured object. For example, **5. Left click on button 'Submit'**.

To redo the previous object capture, click the **Delete** icon at the bottom right of the **Recorder** window to discard the most recent capture.

If Secure recording mode is enabled, a shield icon appears to the right of the red recording icon.

[Secure recording mode](#) on page 2179

7. Click **Finish** after you finish capturing all the necessary objects.

A **Capture** action is generated for each operation.

Where applicable, the **Recorder** generates variables. [Your variables \(user-defined\)](#) on page 2241

8. Edit the actions or click **Save**.

[Edit a task recorded using AI Sense](#) on page 2183

Detect hidden objects manually

If an object is only visible when you hover the mouse over the object, you must manually specify the object type and location by anchoring it to the nearest text:

1. Click the object once.

2. Click **Define**.

The **AI Sense Define main object** window appears with a screenshot of the application, where the object is visible.

3. Click and drag a rectangle to outline the object to capture.**4.** In the **Supporting anchor** list, select the text that is closest to the object you are capturing.**5.** Click **Apply**.

Related tasks

[Edit a task recorded using AI Sense](#) on page 2183

After you have recorded a task using the AI Sense Recorder, you can edit the recorded actions to perform various actions on the captured objects.

Related reference

[AI Sense for recording tasks from remote applications](#) on page 2180

AI Sense is the artificial intelligence (AI) powered capability of Automation 360 that helps you identify objects from an image or an application with a complex user interface (UI) and make automation in all environments faster and more accurate.

[Actions performed on objects captured with AI Sense Recorder](#) on page 2185

After you capture objects using the AI Sense Recorder, you can perform various actions that a bot can perform on the object at runtime.

Edit a task recorded using AI Sense

After you have recorded a task using the AI Sense Recorder, you can edit the recorded actions to perform various actions on the captured objects.

Edit a recorded task to do the following:

- Change the application window in which you want to perform the operation, or add a wildcard to the window title.
- Change the properties of the captured objects.
- Specify the action you want to perform on the captured objects.
- Introduce a delay before the next action is performed.
- Specify the variable you want to use to store the output.

Important: Only the following types of objects are supported with AI Sense Recorder:

- Text boxes
- Check boxes
- Combo boxes
- Radio buttons
- Buttons
- Active text

Active text is the text that you can click. For example, link, menu, text on a navigation pane, and so on. When there are duplicate active texts on the window, the AI Sense Recorder identifies and applies the action of the first occurrence of that active text on the window.

- Passive text

Passive text is the text that you can only read. It can be any text visible on the window that can be associated with a nearby static anchor text that is available during bot execution. When you

select an area that has multiple lines, the AISense Recorder retrieves only the first line of the text from the area.

- Image button

An image button is a button that contains only image and does not have any text associated with it. For example, icons for delete, copy, cut, paste, and so on. You can capture image buttons that are hidden on the application screen and appear when you hover the mouse pointer over them.

- Scroll on an application window and combo box
-

To edit a recorded task, perform the following steps:

1. Open the bot that contains the recorded actions you want to edit.
2. Click the **Capture** action that you want to edit.

Make the following changes, as necessary:

3. Click the **Window** tab or the **Variable** tab to specify a different application window on which you want to perform the operation.

If you have used the **Window** tab to specify the application window, you can use a wildcard character in the **Window title** field. The wildcard character is useful if the title of an application changes. For example, `Sample* - Google Chrome`.

Note:

- During runtime, verify that the Task Bot identifies the correct window.
 - If you use scroll on an application window, you must click the **Analyze window** option to analyze the new objects on the window.
-

4. Update the object properties.

You can only update the value available in the **Anchor** field.

5. Select an option from the **Action** list to specify the action you want to perform on the object. For a full list of possible actions by object, see [Actions performed on objects captured with AISense Recorder](#) on page 2185.
6. Optional: Enter a value in the **Wait for control** field to specify the number of seconds the bot must wait for the object control to appear on the application window.

We recommend setting a delay time when using the Set text action to enter keystrokes into a text field.

7. Optional: Assign the output to a variable.

The Control Room suggests a descriptive default variable name based on the action that you selected previously. For example, if you selected **Get text**, the suggested output variable is `CaptureText`. If you create several output variables, subsequent variable names are suffixed with a hyphen and number to prevent duplication of variable names.

8. Perform the Steps 2 through 7 for the other actions that you want to edit in the bot.
9. Click **Save**.

Link nearby text to a supporting anchor

At run time, if the bot cannot reliably identify an object, link the object to nearby text that is easier for the bot to find:

1. Open the **Capture** action.
-

2. Click the **Anchor** tab.

3. Click **Capture anchor**.

The browser or application window activates with the main object highlighted (the object that you previously captured). A dialog box appears, verifying whether the action has correctly identified the main object.

4. If the correct object is highlighted, click **Yes, Select anchor**.

Otherwise, click **No, I need to correct it** to select the correct object.

5. Select nearby text to the target object that is easier for the bot to find.

The text is highlighted with an anchor icon to the right of the text.

6. Click **Save**.

Actions performed on objects captured with AISense Recorder

After you capture objects using the AISense Recorder, you can perform various actions that a bot can perform on the object at runtime.

For example, when you capture a button, you can select to click the button or to retrieve the button text. The following table lists the objects and their possible actions.

Object	Actions
Button	<ul style="list-style-type: none"> • Get text: Extracts the value or caption from the specified captured object. • Click: Use this action to select the captured object. • Left click: Use this action if the Click action does not work during runtime. • Right click: Use this action to perform the right-click operation on the captured object. • Double click: Use this action to perform the double-click operation on the captured object.
Image button	<ul style="list-style-type: none"> • Left click: Use this action if the Click action does not work during runtime. • Right click: Use this action to perform the right-click operation on the captured object. • Double click: Use this action to perform the double-click operation on the captured object.
Active text	<ul style="list-style-type: none"> • Left click: Use this action if the Click action does not work during runtime. • Right click: Use this action to perform the right-click operation on the captured object. • Double click: Use this action to perform the double-click operation on the captured object.
Passive text	<ul style="list-style-type: none"> • Get text: Retrieves text available in the area you have specified.

Object	Actions
Check box	<ul style="list-style-type: none">• Get text: Extracts the value or caption from the specified captured object.• Get status: Retrieves whether the check box is selected. Returns checked or unchecked.• Check: Selects the captured check box.• Uncheck: Clears the captured check box.• Toggle: Switches the check box to the opposite status. For example, if the check box is selected, use the Toggle action to clear it.• Left click: Use this action if the Toggle action does not work during Runtime.• Right click: Use this action to perform the right-click operation on the captured object.• Double click: Use this action to perform the double-click operation on the captured object.
Combo box (appears as a drop-down list)	<ul style="list-style-type: none">• Get text: Extracts the value or caption from the specified captured object.• Get selected text: Retrieves text from the selected item.• Select item by text: Selects the item that matches the text you have specified in the Assign value field. <hr/> <p>Note: The Assign value field is case-sensitive.</p> <hr/> <ul style="list-style-type: none">• Expand: Expands the combo box.• Click: Use this action to select the captured object.• Left click: Use this action if the Click action does not work during runtime.• Right click: Use this action to perform the right-click operation on the captured object.• Double click: Use this action to perform the double-click operation on the captured object.

Object	Actions
Scroll bar (within a combo box)	<ul style="list-style-type: none">• Scroll Up: Performs the scroll up operation. This action is similar to clicking the scroll up button one time.• Scroll Down: Performs the scroll down operation. This action is similar to clicking the scroll down button one time.• Page Up: Performs the page up operation. This action is similar to holding the scroll bar and moving it up. The distance by which the scroll bar is moved up is specified in the Scroll Distance field.• Page Down: Performs the page down operation. This action is similar to holding the scroll bar and moving it down. The distance by which the scroll bar is moved down is specified in the Scroll Distance field.• Left click: Use this action if the Click action does not work during runtime.• Right click: Use this action to perform the right-click operation on the captured object.• Double click: Use this action to perform the double-click operation on the captured object.
RadioButton	<ul style="list-style-type: none">• Get text: Extracts the value or caption from the specified captured object.• Get status: Retrieves whether the radio button is selected. Returns selected or deselected.• Select: Use this action to select the captured radio button.• Left click: Use this action if the Click action does not work during runtime.• Right click: Use this action to perform the right-click operation on the captured object.• Double click: Use this action to perform the double-click operation on the captured object.

Object	Actions
TextBox	<ul style="list-style-type: none"> • Get text: Extracts the value or caption from the specified captured object. • Set text: Enters the text you have specified in the captured field. It supports credentials. Credentials and credential variables in the Bot editor on page 2254 • Append text: Adds text at the end of existing text in the captured field, instead of overwriting it. • Click: Use this action to select the captured object. • Left click: Use this action if the Click action does not work during runtime. • Right click: Use this action to perform the right-click operation on the captured object. • Double click: Use this action to perform the double-click operation on the captured object.

Capture Image button through AISense Recorder

Image buttons or icons are clickable buttons with no anchors. An application can have one or multiple image buttons. AISense Recorder uses template matching to detect and match image buttons on an application. So even after you record, if the position of the image button changes due to window resizing, AISense Recorder can detect the object and run the bot.

Capture Image button

1. On the left pane, click **Automation**.
2. To create a bot, click **Create new > Bot**, or open a bot for which you want to record a task.
3. Click **Start recording**.

The Recorder bot runtime window appears.

4. Select a window from the drop-down list.
If you opened an application recently and it is not available in the list, click the **Refresh** icon.
5. Click **AISense Recorder** and allow the scanning process to finish.

Note: The AISense Recorder downloads the required dependent files the first time you use it on a device.

The AISense Recorder toolbar appears with these options: **Finish**, **Scan**, **Define**, and **Pause**.

The AISense Recorder analyzes the selected application window to identify the UI objects in that window. When the system is analyzing the application window, the options on the toolbar are unavailable. After the analysis completes, the options are enabled and you can start recording the task.

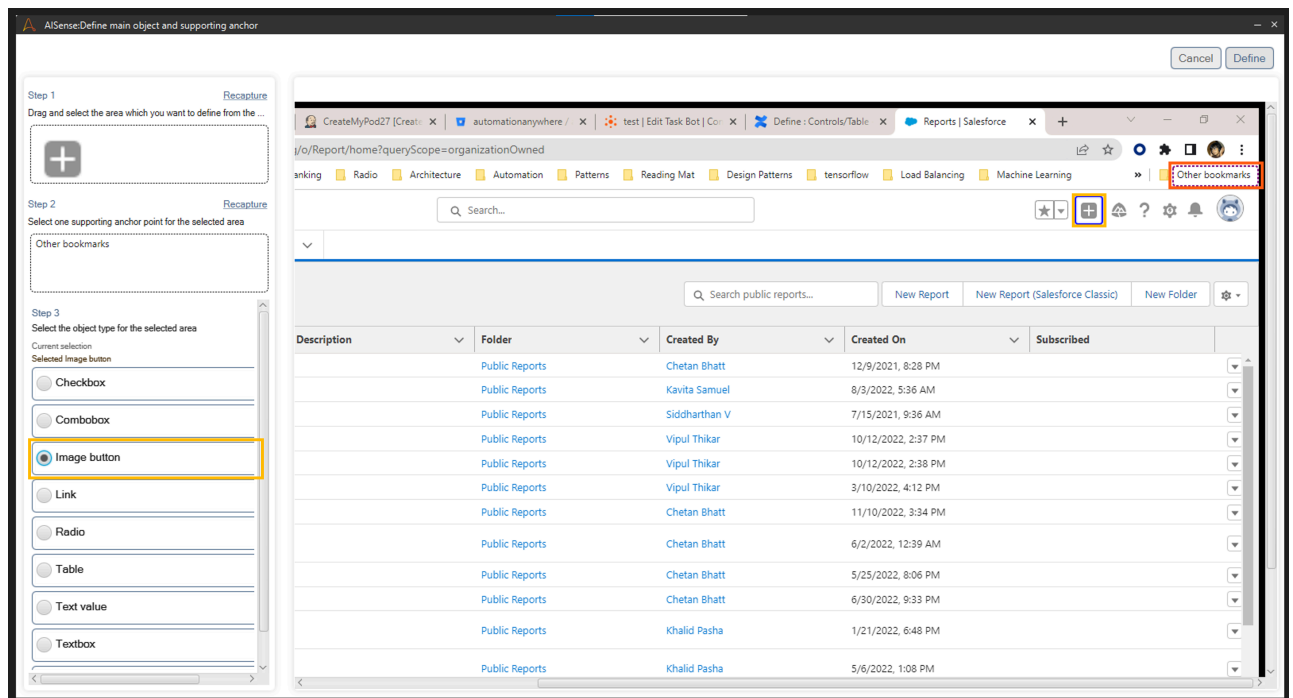

6. Wait for the AISense Recorder to detect the object.

- If the object is not detected automatically, then when the AISense Recorder reaches the **Ready** state, you can click the **Define** button to detect the object.

Note:

- In the **Define** window, the shows embedded help for each control type so you can select the correct control types for custom objects.
- If you unintentionally click the screen or click before the highlighter appears, provides visibility into it. You must confirm to capture the object again, or use the **Define** functionality to define the object on the screen.

- Select **Image button** from the **Select the object type for the selected area** tab.

- Draw a rectangle around the image button that you want to capture.
The selected area is shown in the box below the **Drag and select the area which you want to define from the image** field.
- Hover the mouse cursor over the nearby static text. Once the text is highlighted, select the static text as the supporting anchor.
The image of the anchor is shown in the box below the **Select one supporting anchor point for the selected area** field.
- Click **Define**.
- After you have captured the required objects, click **Finish**.

Capture link button through AISense Recorder

The link button control is clickable and has no specific features. In some cases, the AISense Recorder cannot detect it. You must use the **Define** option to detect and capture the link button control.

Capture link button

1. On the left pane, click **Automation**.
2. To create a bot, click **Create new > Bot**, or open a bot for which you want to record a task.
3. Click **Start recording**.

The Recorder bot runtime window appears.

4. Select a window from the drop-down list.
If you opened an application recently and it is not available in the list, click the **Refresh** icon.
5. Click **AISense Recorder** and allow the scanning process to finish.

Note: The AISense Recorder downloads the required dependent files the first time you use it on a device.

The AISense Recorder toolbar appears with these options: **Finish**, **Scan**, **Define**, and **Pause**.

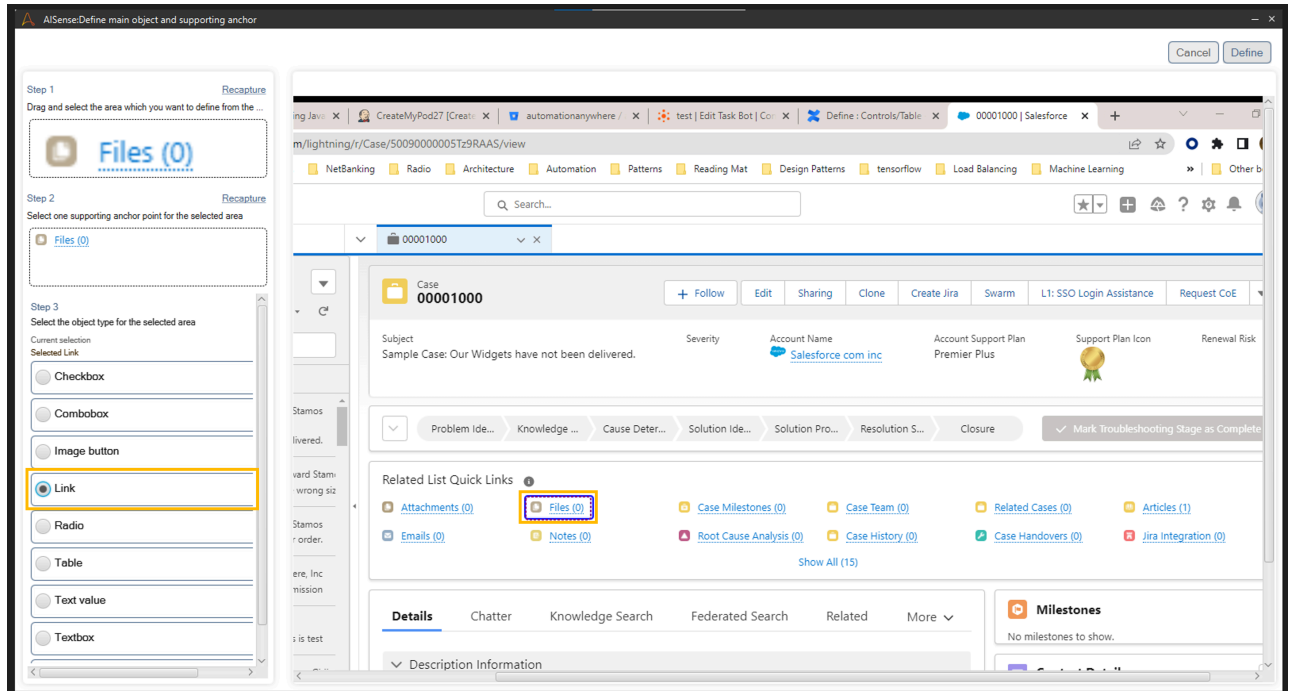

The AISense Recorder analyzes the selected application window to identify the UI objects in that window. When the system is analyzing the application window, the options on the toolbar are unavailable. After the analysis completes, the options are enabled and you can start recording the task.

6. Wait for the AISense Recorder to detect the object.
7. If the object is not detected automatically, then when the AISense Recorder reaches the **Ready** state, you can click the **Define** button to detect the object.

Note:

- In the **Define** window, the shows embedded help for each control type so you can select the correct control types for custom objects.
- If you unintentionally click the screen or click before the highlighter appears, provides visibility into it. You must confirm to capture the object again, or use the **Define** functionality to define the object on the screen.

-
8. Select **Link** from the **Select the object type for the selected area** tab.

9. Draw a rectangle around the link button that you want to capture.
The selected area is shown in the box below the **Drag and select the area which you want to define from the image** field.
10. Hover the mouse cursor over the text. Once the text is highlighted, select the link text as the supporting anchor.
The image of the anchor is shown in the box below the **Select one supporting anchor point for the selected area** field.
11. Click **Define**.
12. After you have captured the required objects, click **Finish**.

Capture text value through AISense Recorder

Passive texts are texts that are readable only. To make decisions, bots might require extracting texts, for example, key-value pair or text value from a form. If the AISense Recorder cannot detect the texts automatically, then you must use the **Define** option to detect the texts.

Capture the text value

1. On the left pane, click **Automation**.
2. To create a bot, click **Create new > Bot** or open a bot for which you want to record a task.
3. Click **Start recording**.
The Recorder bot runtime window appears.
4. Select a window from the drop-down list.
If you opened an application recently and it is not available in the list, click the **Refresh** icon.

5. Click **AI Sense Recorder** and allow the scanning process to finish.

Note: The AI Sense Recorder downloads the required dependent files the first time you use it on a device.

The AI Sense Recorder toolbar appears with these options: **Finish**, **Scan**, **Define**, and **Pause**.

The AI Sense Recorder analyzes the selected application window to identify the UI objects in that window. When the system is analyzing the application window, the options on the toolbar are unavailable. After the analysis completes, the options are enabled and you can start recording the task.

6. Wait for the AI Sense Recorder to detect the object.
7. If the object is not detected automatically, then when the AI Sense Recorder reaches the **Ready** state, you can click the **Define** button to detect the object.

Note:

- In the **Define** window, the shows embedded help for each control type so you can select the correct control types for custom objects.
- If you unintentionally click the screen or click before the highlighter appears, provides visibility into it. You must confirm to capture the object again, or use the **Define** functionality to define the object on the screen.

-
8. Select **Text value** from the **Select the object type for the selected area** tab.

9. Draw a rectangle around the text area that you want to extract.

The selected area is shown in the box below the **Drag and select the area which you want to define from the image** field.

10. Hover the mouse cursor over the nearby static text. Once the text is highlighted, select the static text as the supporting anchor.

The image of the anchor is shown in the box below the **Select one supporting anchor point for the selected area** field.

11. Click **Define**.
12. After you have captured the required objects, click **Finish**.

Known behavior

AI Sense Recorder cannot extract texts with multiple lines. If you select multiple lines, only the first line is extracted.

Capture Textbox, Radio, Checkbox, and Combobox

When a screen is dense, sometimes the AI Sense Recorder cannot detect and classify the controls correctly. To continue to automate the controls seamlessly, you can use the AI Sense Recorder to capture coordinates of controls and perform certain actions without having to use the Mouse and Simulate keystrokes packages separately.

Textbox, Radio, Checkbox, and Combobox

Note: Any textbox, radio, checkbox, and combobox controls captured using **Define** functionality will be coordinate based automation. This functionality is provided for continuity of workflow.

1. On the left pane, click **Automation**.
2. To create a bot, click **Create new > Bot** or open a bot for which you want to record a task.
3. Click **Start recording**.
The Recorder bot runtime window appears.
4. Select a window from the drop-down list.
If you opened an application recently and it is not available in the list, click the **Refresh** icon.
5. Click **AI Sense Recorder** and allow the scanning process to finish.

Note: The AI Sense Recorder downloads the required dependent files the first time you use it on a device.

The AI Sense Recorder toolbar appears with these options: **Finish**, **Scan**, **Define**, and **Pause**.

The AI Sense Recorder analyzes the selected application window to identify the UI objects in that window. When the system is analyzing the application window, the options on the toolbar are unavailable. After the analysis completes, the options are enabled and you can start recording the task.

6. Wait for the AI Sense Recorder to detect the object.
7. If the object is not detected automatically, then when the AI Sense Recorder reaches the **Ready** state, you can click the **Define** button to detect the object.

Note:

- In the **Define** window, the shows embedded help for each control type so you can select the correct control types for custom objects.
 - If you unintentionally click the screen or click before the highlighter appears, provides visibility into it. You must confirm to capture the object again, or use the **Define** functionality to define the object on the screen.
-

8. Select the specific object type from the list of object types from the **Select the object type for the selected area** tab.

The object types that you select is shown under **Current selection**.

9. Draw a rectangle around the control that you want to capture.

The selected area is shown in the box below the **Drag and select the area which you want to define from the image** field.

10. Hover the mouse cursor over the text. Once the text is highlighted, select and define the text as the supporting anchor for identification.

The image of the anchor is shown in the box below the **Select one supporting anchor point for the selected area** field.

11. Click **Define**.
12. After you have captured the required objects, click **Finish**.

Table data extraction through AISense Recorder

Tables are a complex control, with many types, backgrounds, and formatting effects, and hence might not be automatically detected by AISense Recorder in some cases. In such cases, use the **Define** option to detect tables.

Capture a table using AISense Recorder

1. On the left pane, click **Automation**.
2. To create a bot, click **Create new > Bot** or open a bot for which you want to record a task.
3. Click **Start recording**.
The Recorder bot runtime window appears.
4. Select a window from the drop-down list.
If you opened an application recently and it is not available in the list, click the **Refresh** icon.
5. Click **AISense Recorder**. Let the scanning process finish.

Note: The first time you use AISense Recorder on a device, the Recorder downloads the required dependent files.

The Recorder toolbar appears with the following options: **Finish**, **Scan**, **Define**, and **Pause**

The Recorder analyzes the application window that you selected to identify the UI objects in that window. The options on the toolbar are unavailable when the system is analyzing the application window. After the analysis, the options are enabled and you can start recording the task.

6. Wait for AISense Recorder to detect the table in the application.
7. If the table is not detected automatically, then when AISense Recorder is in the **Ready** state, click the **Define** button to detect the table.

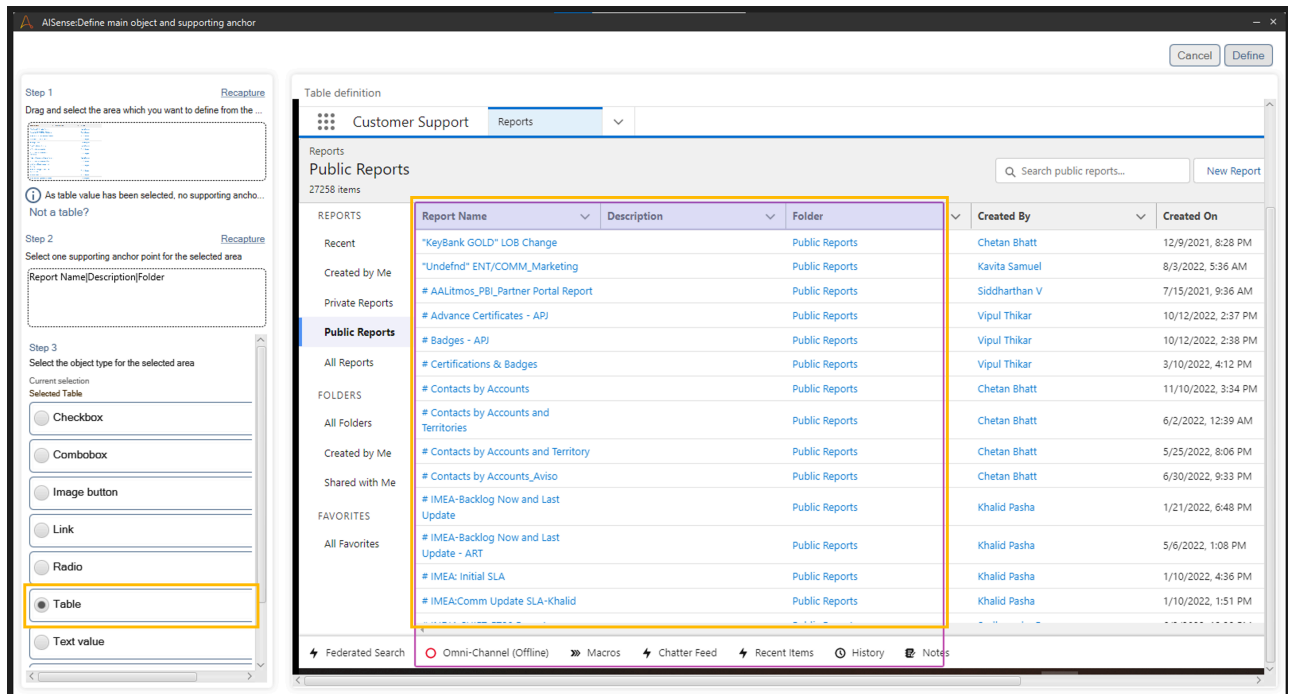

Note:

- In the **Define** window, the shows embedded help for each control type so you can select the correct control types for custom objects.
- If you unintentionally click the screen or click before the highlighter appears, provides visibility into it. You must confirm to capture the object again, or use the **Define** functionality to define the object on the screen.

-
8. Select **Table** from the **Object type** tab and click the top-left header.
The detected table will be highlighted with columns and internal controls.

9. If you want to select a limited set of columns, then draw a rectangle around the columns that you want to capture.

Extract data from a table

1. After the object is captured, click **Finish** to end the recording.

2. Return to the Control Room.
3. In the **Object properties** table, verify that the **Control Type** is TABLE. If it is not, click **Recapture object**.
4. From the **Action to take on object** drop-down list, select **Get table**.
5. In the **Save the outcome to a variable** field, create the CapturedTableData variable.
6. Double-click or drag the **Data Table > Write to file** action.
7. From the **Data table name** list, select CapturedTableData.
8. Provide a filepath to create a CSV file. For example, C:\AutomationAnywhere\Development\SFDC.csv
9. Select the **Create folders/files if it doesn't exist** option.
10. Select to overwrite the existing file.
11. Click **Save**.
12. Click **Run**.

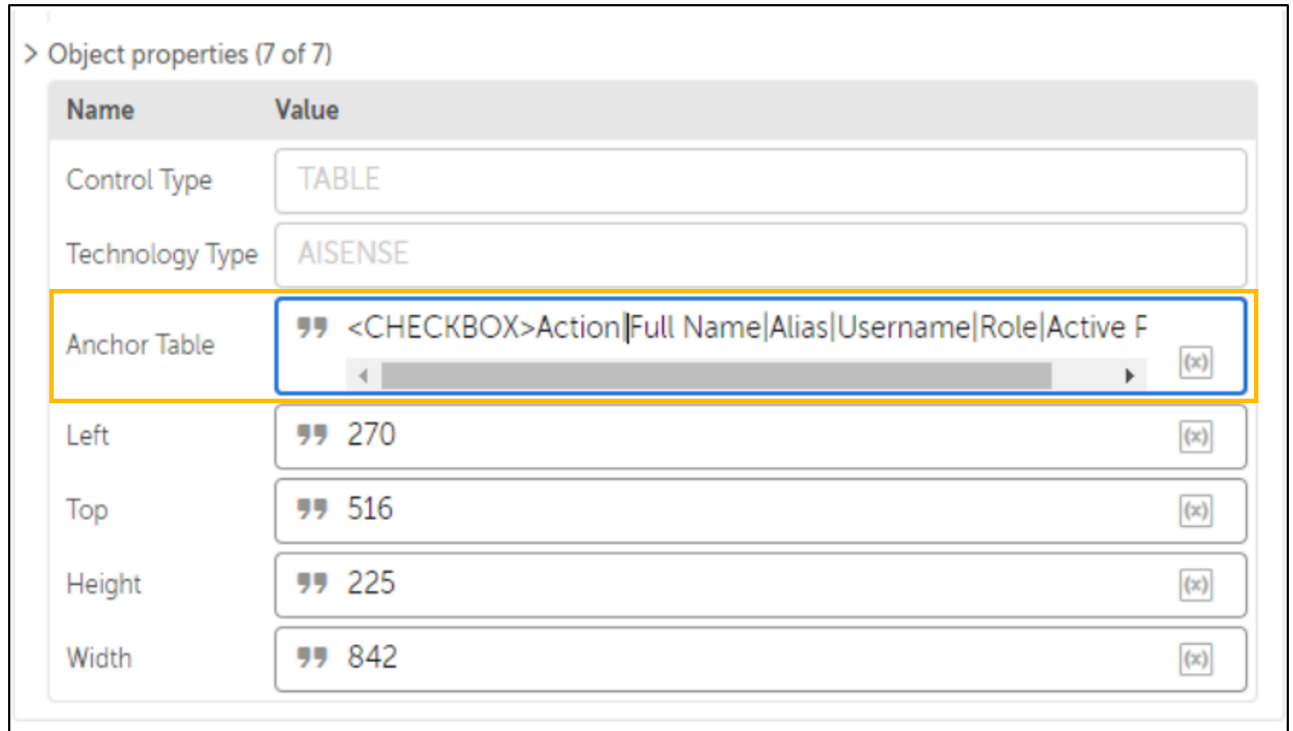

The bot creates a CSV file in the specified path with the table data extracted.

Correct a column definition

It is possible that dense tables can merge columns due to less space between columns or lack of clear separators. To correct the column definition, perform the following steps:

1. After the object is captured, click **Finish** to end the recording.
2. On the Bot editor window, go to **Object properties** to edit the **Anchor Table** property.
3. Add the pipe character (|) as a delimiter between the column names to separate them. For example, <CHECKBOX>Name|Company|State|Email|Lead status

Note: When the bot is run, previously merged columns will be treated as separate columns.

Known behavior

- AI Sense Recorder cannot extract tables with multiple lines in single rows or cells.
- Pagination and autoscrolling are not supported.
- Truncated columns will not be automatically adjusted to extract truncated cell text.

Use variable anchor

You can use the variable anchor to automate same controls that have different anchors. For example, pages having multiple checkboxes with different captions. These captions might be dynamic and might change based on the workflow. You can use the variable anchor to capture the control once, and then use the anchor as a variable in the Bot editor window. You can use a variable from various sources, for example, Microsoft Excel, CSV, or database.

Capture using variable anchor

1. On the left pane, click **Automation**.
2. To create a bot, click **Create new > Bot** or open a bot for which you want to record a task.
3. Click **Start recording**.
The Recorder bot runtime window appears.
4. Select a window from the drop-down list.
If you opened an application recently and it is not available in the list, click the **Refresh** icon.

- Click **AI Sense Recorder** and allow the scanning process to finish.

Note: The AI Sense Recorder downloads the required dependent files the first time you use it on a device.

The AI Sense Recorder toolbar appears with these options: **Finish**, **Scan**, **Define**, and **Pause**.

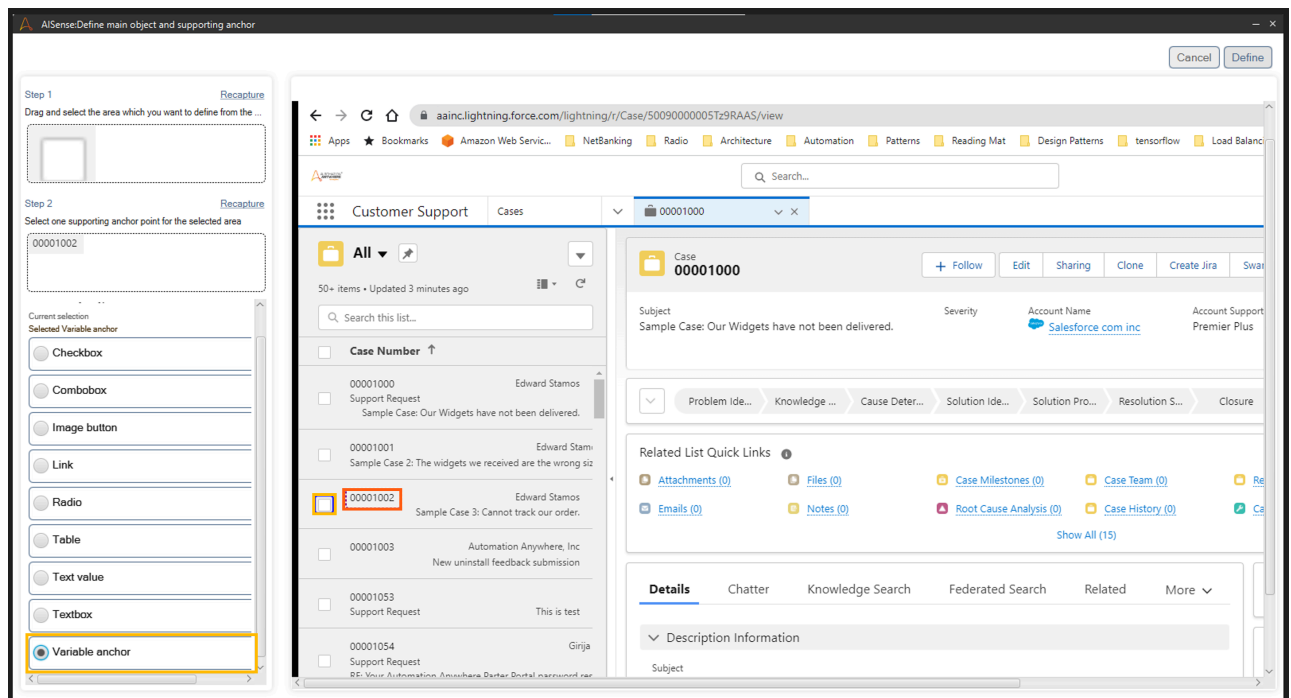

The AI Sense Recorder analyzes the selected application window to identify the UI objects in that window. When the system is analyzing the application window, the options on the toolbar are unavailable. After the analysis completes, the options are enabled and you can start recording the task.

- Wait for the AI Sense Recorder to detect the object.
- If the object is not detected automatically, then when the AI Sense Recorder reaches the **Ready** state, you can click the **Define** button to detect the object.

Note:

- In the **Define** window, the shows embedded help for each control type so you can select the correct control types for custom objects.
- If you unintentionally click the screen or click before the highlighter appears, provides visibility into it. You must confirm to capture the object again, or use the **Define** functionality to define the object on the screen.

- Select **Variable anchor** from the **Select the object type for the selected area** tab.

- Draw a rectangle around the checkbox that you want to capture.

The selected area is shown in the box below the **Drag and select the area which you want to define from the image** field.

Note: Hover the mouse over the checkbox and ensure that the checkbox is detected and highlighted with red rectangle before you click **Define**.

- 10.** Hover the mouse over the closest static text. Once the text is highlighted, select the text as the supporting anchor.

The image of the anchor is shown in the box below the **Select one supporting anchor point for the selected area** field.

- 11.** Click **Define**.
- 12.** After you have captured the required objects, click **Finish**.

The recorded steps appear as a separate action in the bot.

For each variable anchor action, you can copy the added action and update the value in the **Anchor** field with the anchor text of the object you want to capture, for each variable anchor action. Alternatively, you can use the action within the Loop action and use a variable that supports the String data type in the **Anchor** field.

> Object properties (7 of 7)

Name	Value
Control Type	VARIABLE_ANCHOR
Technology Type	AISENSE
Anchor	☞ \$AnchorInput\$ (x)
Left	☞ 47 (x)
Top	☞ 275 (x)
Height	☞ 21 (x)
Width	☞ 21 (x)

Keep trying for (seconds)

15 (x)

How long we'll search for the object (time out)

Note:

- You can assign only highlighted controls to a variable.
- Ensure no additional control or text exists between the anchor and the control.

Enable debug logs for AISense Recorder

You can use debug logs to troubleshoot the application window that you capture and to verify if the object is being detected correctly. The results are available as debug images in the %temp%\AISenseLogs folder.

1. On your local device, browse to C:\Program Files\Automation Anywhere\Bot Agent\config.
2. Open the botlauncher-logging.xml file.
3. Include the following logger entry within the <Loggers> XML element and save the XML file:
<Logger name="com.automationanywhere.recorder" level="DEBUG"/>
For example, add the debug logger entry below the existing logger entry.

```
<Logger name="com.automationanywhere.recorder" level="INFO"/>  
<Logger name="com.automationanywhere.recorder" level="DEBUG"/>
```

Changes you make to the logging configuration file are updated in seconds configured per the monitor interval value.

Note: If the changes are not automatically applied per the monitor interval value, restart the Bot Agent service.

AISense Recorder best practices

To use the AISense Recorder optimally, review the best practices.

Configuring registered devices

- Ensure you use only recommended hardware configuration for registered device as specified. See [Bot Runner device requirements](#) on page 1111
- If application is running on same device, we recommend you to add additional CPU or RAM to avoid slowness. See [Bot Runner device requirements](#) on page 1111
- If you are automating a task using a browser, ensure that auto-fill is disabled for that browser.
- Ensure that the screen resolution is set to 1980x1080 or lower. See [Record a task with AISense Recorder](#) on page 2181
- Configure the device display settings to 100% DPI. See [Record a task with AISense Recorder](#) on page 2181

Behavior

- When you use the AISense Recorder for the first time on any device, either for recording or for playback, it downloads the required resources from the Control Room. This process might take a few or several minutes depending on the speed of your internet. The state of the process is indicated in the progress bar during recording and the Bot runtime window shows **Downloading additional resources**.
- When you use a new package in a bot and if the package has any updated resources, it gets downloaded automatically that results in a delay in bot execution.
- There is a delay in scanning or bot execution in the following cases:

- The first execution will setup AISense environment which will take couple of seconds (based on machine configuration). User will observe some delay in scanning and bot execution.
- Every time application changes, due to navigation or new controls loaded, AISense has to detect new available controls on the application screen, which will take couple of seconds (based on machine configuration). User will observe some delay in scanning and bot execution.
- Parent and child bot execution: If child bot is using AISense Recorder, every time the child bot is executed, an AISense environment gets created to maintain isolation between bots. User will observe some delay in bot execution.

Methodology

- Record the task at low speed. Click only after the red highlighter appears around the object.
- Avoid dragging the windows during the recording process.
- If AISense Recorder is downloading required resources from the Control Room in case it is deployed for the first time, do not close the Recorder window in between since doing so might corrupt the required resource files.
- When the AISense Recorder is in **Scanning** state, avoid switching between applications.
- When the AISense Recorder is in **Ready** state, move the mouse slowly over the object or control that you want to capture and make sure that it gets highlighted with the red rectangle and then click on it.

Capturing Combo box

The following are some best practises that you can follow when you use the AISense Recorder to capture combo boxes. Below are some of the combo boxes based on the application requirements.

- **Searchable combo box:** The searchable combo box enables you to click in the text area and type. It then starts filtering the typed text from the list and allows you to press enter when a single result is available.
 - To automate this combo box control, during recording, highlight the combo box and click in the center of the combo box. The default action selected will be **Select Item by Text**. Finish the recording.
 - Go back to control room bot editor. Enter the text value along with Enter or combination of Down (down arrow) and Enter to simulate user like action. For example, if you are automating a searchable combo box which has a dropdown list item, then you can either enter the value in the searchable combo box and click Enter to select it or use the down arrow to search for the specific value and click Enter to select that value from the list.
- **Legacy combo box:** The legacy combo box does not have a search functionality and it is mandatory to expand it by clicking triangular button on right side of combo box and select one of the value.
 - To automate this combo box control, during recording, highlight the combo box, it should also highlight the small triangular button on right side.

Note: Ensure that it also highlights the small triangular button on the right side.

- Click the button and wait.
The Recorder must take sometime to identify expanded value. During this time, the recording icon in the Recorder window must be in the blinking state.
- As soon as the small recording icon stops blinking, hover the mouse over the list box (expanded combo box) and make sure it highlights list values.
- Select the specific values.
- User can select any value and later change it from the Bot editor window in the Automation Anywhere Control Room.

Using AISense Recorder with other Packages

AISense Recorder is computer vision based object detection method of automating where it captures the image of the application that you want to automate. When you use AISense Recorder to automate applications that have objects like textbox with single underline or combobox without triangular button, the objects might not get detected. In such cases, we recommend you use a combination of AISense Recorder with other packages like OCR and Image Recognition packages or only OCR and Image Recognition packages to automate such use cases.

Client Control

AISense Recorder detects object on the application with specific feature set. When you click an area where there is no control, or click a control before it highlights with red boundaries, it will be recorded as **CLIENT** control. The client control is coordinate based capture of mouse click to replicate user click and is not standard AISense control. We recommend user to recapture control if captured as **CLIENT** control.

Working with bots

Depending on the license and permission assigned to you, you can perform various bot operations and access the private and public workspaces in the Control Room.

Licenses

Two types of licenses are available: Bot Creator and Bot Runner (attended or unattended) licenses. [Automation 360 licenses](#) on page 1347

Bot Creator tasks

A Bot Creator user can access both the private workspace and public workspace in the Control Room by navigating to **Automation** on the left panel. The license provides the user exclusive access to the registered device. Other users cannot use the default device of a Bot Creator.

With the Bot Creator license and specific permissions, you can perform the following tasks:

- [Create a bot](#)
- [Run a bot](#) on page 2206

- Record a bot
 - Record a task with the [Universal Recorder](#) on page 2164|[Record a task with AI Sense Recorder](#) on page 2181
- [Schedule a bot](#) on page 2056
- [Copy a bot](#) on page 2220
- [Assign label to a bot](#)
- [View bot version history](#)
- [Export a bot](#)
- [Import a bot](#)
- [Check in a bot](#) on page 2210
- [Check out a single bot](#) on page 2214
- [Delete a bot](#)

You can also edit, analyze, save, clone, view content, pause, or stop a Task Bot.

Bot Runner tasks

A Bot Runner can access only to the public workspace in the Control Room. They cannot create or edit bots.

With the Bot Runner license and specific permissions, you can perform the following tasks:

- [Run a bot](#) on page 2206
- [Schedule a bot](#) on page 2056
- [Assign label to a bot](#)

You can also view the content of a Task Bot.

Public and private workspaces

The Automation page lists all the folders and bots available within the selected folder in the **Public** and **Private** repositories. If you have migrated the Enterprise 11 or Enterprise 10 data to Automation 360, the Automation page additionally displays the Enterprise 11 or Enterprise 10 Task Bots (.atmx) and MetaBots (.mbot) files in the public repository.

When an Enterprise 11 or Enterprise 10 bot is migrated and converted to the Automation 360 bot, the **My Tasks** and the **My Metabots** folders display the migrated (Enterprise 11 or Enterprise 10) and the converted bots with the same name but different extension. This might create confusion to differentiate between the two bots. Also, you cannot take any actions on the migrated bots except deleting them. To avoid this confusion, you can use the **Show** menu option to show or hide the Enterprise 11 or Enterprise 10 bots.

The Show menu displays three options - **Folder**, **.ATMX Task Bot**, and **.MBOT Meta Bot**. By default, each of these options are selected and displays all the folders and sub folders along with the Enterprise 11 or Enterprise 10 bot files.

If you clear the selected **Folder** option, then the sub-folders will be hidden from the files and folders list and will only display **.atmx** or **.mbot** files and when you clear the selected **.ATMX Task Bot** or the **.MBOT Meta Bot** options, the **.atmx** or **.mbot** files, will then be hidden across all the folders.

Depending on the license, users logging in to the Control Room can access the private and public workspaces.

Private workspace

Users with the Bot Creator license can access the private workspace. This workspace is primarily used to create and test bots. It enables users to view and manage all their activities in one primary location. Bots in the private workspace is available only to the users who created them.

Note:

- Users with administrative privileges and Bot Runner license cannot access the private workspace because they cannot create bots.
- The bot name must be unique. If a bot or a folder with the same name exists in the same folder location which you have access to in the public workspace, you cannot either create, check out, or rename the bot with this name in the private workspace.

Public workspace

Both Bot Creator and Bot Runner users can access the public workspace. This is a shared workspace where you can execute the bots.

Users with the Bot Runner license can run bots created by the Bot Creator user. Bots created in the private workspace by Bot Creators can be made available to specific Bot Runner users in the public workspace by defining the permissions at the folder or file level. To do this, users have to first check in the bot from the private workspace to the public workspace.

Note:

- When you create a Task Bot with dependencies, ensure that both the parent and child bot are in the same workspace (public or private). You cannot call a public bot from a private bot. To call a bot from the public workspace, you should first check-out or clone the public bot into the private workspace, include it as a child bot inside the private bot, and check-in both the bots.
- Folder names in private and public workspaces are case-sensitive. You can create a folder with the same name and matching case in private and public workspaces. However, you cannot create folders with the same name but with different case in the workspaces. For example, you can create a folder My Metabots in both private and public workspace. However, you cannot create folder names that use the same name but with different case, such as My Metabots in the private workspace and My MetaBots in the public workspace.
- Sorting and filtering are supported for substrings. For example, if you want to search for bots or files that have `fin` in the file or bot name, enter `fin` as the search criterion. All the

bots and files that contain `fin` in the names will be displayed, for example, Finance, Finder, DeltaFinance, and Dolfin.

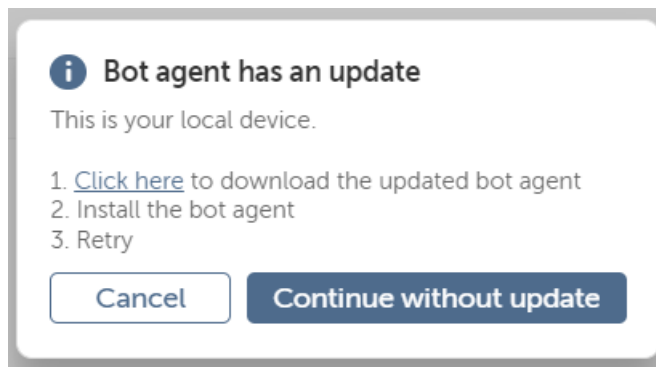

Wildcards are not supported for searching and filtering bots or files.

Run a bot

You can run a bot to test an automated process.

1. Log in to the Control Room.
2. On the left pane in the public workspace, click **Automation**.
A list of available bots and forms is displayed.
3. Select the bot to run. Hover over the actions menu (vertical ellipses) located to the right of the bot name and click **Run Task Bot**.

If an optional Bot Agent update for your device is available, the following message that Bot Agent has an update is displayed one time per user session or when you log out and log in to the Control Room.

- To download and update the Bot Agent to the latest version on your device, use the **Click here** link.
 - To opt out of the update and continue with the existing Bot Agent version on your device, click **Continue without update**.
4. Select the version of the bot to run.
 - Latest version: To select the latest version of the bot, click the **Latest version** tab.
 - Labeled version: To select the labeled version of the bot, click the **Production version** tab.

By default, the latest version of the bot is selected. If the production label option is selected for the parent bot, the corresponding dependent bots with the production label are also automatically selected. If any of the dependent bots do not have the production label applied, the latest version of the bot is selected.

5. Click the right arrow (→) to add your selection.
6. Select the Bot Runner users from the list of **Available bot runners** in the **Run as** tab.
The list of Bot Runner users that you have access to are displayed.
7. Click the right arrow (→) to add your selection.
8. Select the pool from the list of **Available device pools** in the **Device pools** tab.
The list of device pools for which you have a consumer role are displayed. Select the device pool only if any of the selected Bot Runner users do not have a bot running (default) device.

9. Click the right arrow (→) to add your selection.
10. Optional: Select the **Automation priority** from the **General** tab.
Set the priority to high, medium, or low based on your requirements for resource optimization. The default permission is set to medium.
11. Click **Run bot now**.

Note: If you have not set the device credentials from the **My settings** page, you are prompted to provide the device credentials to run the bot.

If you encounter issues in running a bot, refer to the following articles:

- [Automation 360 - Unable to download the bot or the dependencies to the device; Error code: download.error \(A-People login required\)](#).
- [There is already an existing deployment in-progress for this user session \(A-People login required\)](#).
- [BOT stuck in In Progress Stage and not able to move it to history" or "BOT stuck in Pending execution Stage and not able to move it to history" on Automation 360 CLOUD and On-Prem environments](#)

Considerations for running a bot

There are certain considerations you have to keep in mind when running a bot.

- As a Bot Creator, you can deploy a bot on your device or you can run the bot on a remote machine through RDP connection.
- If you are running bots on your local machine as a Bot Creator, enter only your username in the device login credentials; no password is required. The username is required to confirm that the same user who logged in to the local device is deploying the bot. If you are using the Google Chrome plug-in and running bots on your local machine, your username is required.
- As a Bot Runner, you can either deploy the bot yourself or select a run-as user assigned by the administrator. You can run the bot either through your device or choose from the list of devices in a device pool. If you choose to override the default device, the bot will be executed on any available device in the device pool for each run-as user.
- You can preload packages on your local device to shorten the bot runtime.

The system supports running only one bot for each device at a given time. If a bot is already running on the device, you cannot deploy another bot on the device.

While a bot is running on a device, if you try to deploy another bot on the same device, the second bot is queued according to its type. After the deployment of the currently running bot is complete, the queued bot is automatically deployed on the same device.

- If you are running a bot from the Bot editor, closing the Control Room web browser will stop the bot run.
- Run-as user: A set of unattended Bot Runner users that a scheduler can select from to run a bot on a device. The run-as user can select an available device from the device pool to run the bot.
- When bots are queued for a Bot Runner user, bots with higher priority are deployed before bots with lower priority. However, if a bot with lower priority is already running, bots with higher priority are deployed after the bot with lower priority completes running.
- When you create the bot deployment using the **Run bot now** option, the bot is queued for execution. If the bot is deleted while it is queued for execution or while it is active, an error is displayed for that bot in the **In progress activity > View activity** page.

- Attended Bot Runner, Bot Creator, and Citizen Developer users can run the bots using either the **Run bot now** option in the Bot editor or the shortcut key F5. However, unattended Bot Runner users can run their bots only using the **Run bot now** option.

The following table explains the different scenarios where you should choose device pools against bot running devices for the run-as user.

Option	Scenario	Device pool	Default device	Result
Run bot now	Information security compliance where the user cannot log in to any other device	No	Yes	Bot deploys on the default device of the user.
	Specialized application access restricted to a user	No	Yes	Bot deploys on the default device of the user.
Schedule bot	Override bot running device option is selected	Yes	Yes	Bot deploys on the available device in the device pool.
	Override bot running device option is not selected	Yes	Yes	Bot deploys on the default device of the user. If default device is not available, the bot deploys on the available device in the device pool.
	Information security compliance where the user cannot log in to any other device	No	Yes	Bot deploys on the default device of the user.
	Specialized application access restricted to a user	No	Yes	Bot deploys on the default device of the user.
WLM (Run bot with queue)	Run on bot running devices option is selected	Yes	Yes	Bot deploys on the default device of the user.
	Run on bot running devices option is not selected	Yes	Yes	Bot deploys on the default device of the user. If default device is not available, the bot deploys on the available device in the device pool.
Automation Co-Pilot on the web	Run-as user with device pool assigned	Yes	No	Bot deploys on the available device in the device pool.

Related tasks

[Add queue, Bot Runner, and device pool](#) on page 1823

Add a queue, Bot Runner, and device pool to the automation from the **Run bot with queue** page.

Run a bot in elevated mode

You can run a bot in elevated mode to enable non-administrative users to run an automation on applications that require administrative privileges.

To run bots in elevated mode:

- If the user has administrative credentials, then enable the **Run with administrative privileges** option in the **Run bot now** wizard.
- If the user does not have administrative credentials, then run the `A360Elevator.exe` application in an elevated or administrator mode.

Note: The `A360Elevator.exe` is bundled with the Bot Agent in the Automation 360 installation.

As an administrator, run the `A360Elevator.exe` in an elevated mode using one of the following methods:

- Right-click the `A360Elevator.exe` application and select **Run as administrator**.
- Create a shortcut of the `A360Elevator.exe` and add it to the Start up program. See [Add an app to run automatically at startup in Windows 10](#).
- Run the application through a job scheduler (such as Windows Task Scheduler) to enable the Control Room users to run bots in elevated mode.

Elevated mode example

A user without administrator privileges runs a bot without elevated mode

In this example, a Control Room user runs a bot and this user does not have administrator credentials on the device. However, this bot accesses a Notepad application that requires administrator credentials. The following video shows the message that is displayed when the bot run fails:

A user without administrator privileges runs a bot in elevated mode

After installing the new Bot Agent, an IT administrator runs the `A360Elevator.exe` application in an elevated mode from the following location:

```
C:\Program Files\Automation Anywhere\Bot Agent
```

The following video shows how the same Control Room user can now run the bot that accesses the Notepad application which requires administrator credentials and complete the execution.

Verifying the `A360Elevator.exe`

- To verify if the `A360Elevator.exe` is running, open the **Task Manager** as an administrator and review the **Details** tab.
- Search for one of the following lines in the success log:
 - Trying to launch elevated process using `A360Elevator.exe` in session '2'.
 - Successfully launched process in elevated mode.

- Search for one of the following lines in the error log:
 - Trying to launch elevated process using `A360Elevator.exe` in session '2'.
 - Launching process using elevated process token has error {}.
 - Not able to launch process as elevated.

Move a bot

As a Bot Creator, you can now move your bots and files from one folder to another with ease in the private workspace. If a bot is placed in an incorrect folder, you no longer have to clone it in the correct folder and then delete it from the incorrect folder.

- You can move only newly created bots and files or folders containing the newly created bots and files. Checked-out, edited, and cloned bots cannot be moved.
 - You can move bots or files only in the private workspace and not in the public workspace.
1. Log in to the Control Room as a Bot Creator user.
 2. Select the bot or file to move. Hover over the actions menu (vertical ellipsis) located to the right of the bot or file name and click **Move Task Bot**.
 3. Browse and select the folder to which you want to move the bot and click **Choose**. The bot is copied to the destination folder and removed from the source folder.

Note:

- When the bot is moved, you will see a warning message to change the reference in all the parent bots.
- You can move a folder or a sub-folder into another folder when the number of items in the folder is less than 100. An error message is displayed if the folder contains more than 100 items (including metadata).

See the following video to understand how to move bots and files between folders.

Check in a bot

Check in the bot files or folders to the public workspace from private workspace to make it available for all users who have the permission to access and run the bot.

- You must have Bot Creator or Citizen Developer license to check in a bot to the public workspace.
- You must be assigned a custom role with the following permissions:
 - Required: Check in permission at the folder level and at the corresponding parent folder level in the public workspace.
 - Optional: Create folder permission.
 - Optional: View packages permission.
- To check in a bot with dependent folders and files, ensure you have the following:
 - Create folder permission.

If you are checking in a bot from your private workspace and if the folder in which the bot is present does not yet exist in the public workspace, you must have create folder permission to successfully check in the bot.

- Check in permission on the dependency folder.
- Ensure that your private and public workspaces have the same folder structure so that when you check in a bot from your private workspace, it will appear in the same folder structure in the public workspace.
- For example, if you check in a bot from the sample bot folder in the private workspace, it will appear in the sample bot folder in the public workspace.

If you want to check in multiple bots as a unit that are not dependent on each other, create a main bot and then add the other bots as dependencies to this main bot. Check in the main bot.

1. Log in to the Control Room as a Bot Creator or a Citizen Developer user.
2. On the left pane, click **Automation** in the private workspace.
A list of available bots and forms is displayed.
3. You can choose to check in either one bot or multiple bots simultaneously.
 - Check in a single bot.
 - a) Select the bot that you want to check in, click the actions menu (vertical ellipsis), and click **Check in Task Bot**.
 - b) In the **Check in Task Bot** window, add your comment and click **Check in**.

Note: Directly referenced dependencies are checked in by default. The **General** tab shows only the immediate dependencies; however, all the nested dependencies are displayed in the **Review dependencies** tab, and these are also checked in.

For example, consider a scenario where we have parent bot Acme Insurance having departments as child bots HR, Sales and Marketing, and IT services. These child bots have dependencies Employee details, Employment type, and Employee status.

When you check in the parent bot Acme Insurance, in the general dependency tab, only the direct dependencies HR, Sales and Marketing, and IT services are displayed and selected to be checked in by default.

The review dependencies tab displays all these child bots along with the other available nested dependencies such as Employee details, Employment type, and Employee status that are also checked in along with the parent bot.

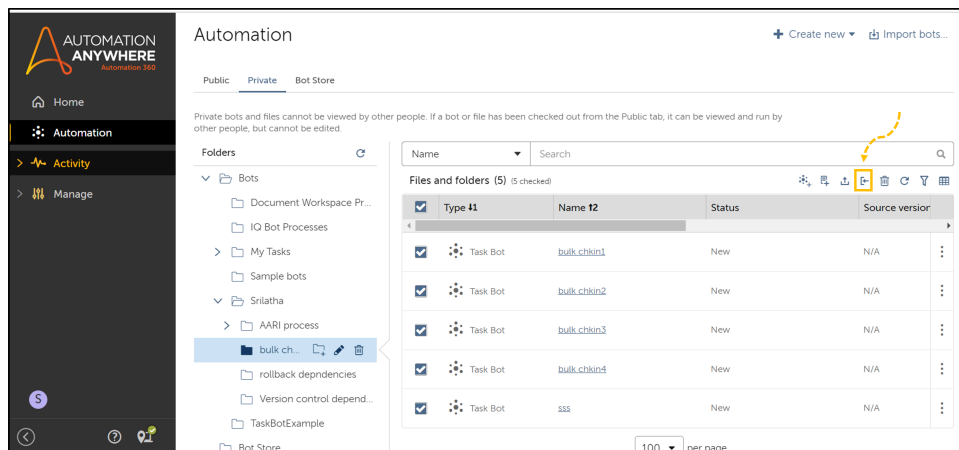

- Check in multiple bots.

Note: You can check in up to 10 bots at a time.

- Select the bots that you want to check in and click **Check in checked items**.

Note: All the inherited dependencies are included to be checked in.

- Add the comment and click **Check in**.
- Optional: Select **Advanced options** to view or modify the selected dependencies, add the comment, and click **Check in**.

The bot appears in the same folder structure in the public workspace.

Note:

- You cannot check in a bot file if another bot file already exists in the same location in the public workspace.
- When you check in a bot along with a cloned bot and no other bots are dependent on the clone, the cloned bot is deleted.

If you have issues in checking in a bot, see [Unable to check-in the bots in Automation 360 \(A- People login required\)](#).

Checking out a bot and dependencies

The check out process enables you to create an editable copy of the bot in the private workspace from the public workspace for further modification.

After you have modified the bot, you can check in the bot again to the public workspace so that it can be deployed by all users who have permission to access it. You can choose the specific version of the bot and its dependencies (bot and non-bot) during the check-out process.

You can cancel the checked-out bot from your private workspace whereas an administrator can cancel the checked-out bot from the public workspace. This releases the bot for another user who has access in the public workspace. When you cancel check out, the bot status changes to **Public** in the public workspace. In the private workspace, the status changes to **New** if any edits are made to the bot. If there are no changes, the bot is replaced with a clone.

Guidelines for checking out bots

While checking out a bot, keep the following considerations in mind:

- If you want to check out multiple bots as a unit that are not dependent on each other, create a main bot and then add the other bots as dependencies to this main bot. Check out the main bot.
- Only one user can check out a bot at a time. When a user checks out a bot, it cannot be checked out by any other user.
- If you are checking out a parent bot in the public workspace whose dependencies are checked out by another user, the dependencies of the parent bot will be cloned in your private workspace.
- If a bot is checked out, it cannot be deleted. The bot should be in a checked-in (**Public**) state to be deleted.
- When you edit a checked-out bot, the status changes to **Checked out edited**.

You can use the **Revert edits** option to revert changes you made to the checked-out bot.

- During check out, a cloned bot can be overwritten or replaced.
- The dependent files are automatically cloned if they are checked out by another user and you have the **Clone** permission on the bot folder.
- The bot check-out timeout value is 30 minutes. If you have a large bot, sometimes the bot might not check out within 30 minutes, and the check-out operation fails. Break your bot into logical sub-bots so that they are easily manageable and checked out in less time.

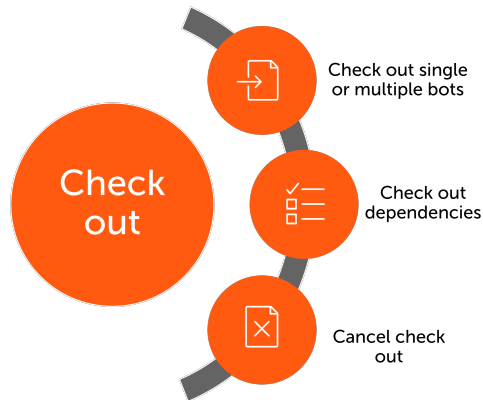

Prerequisites for checking out bots and dependencies

- You must have Bot Creator or Citizen Developer license to check out a bot to your private workspace.
- You must have check out permission at the folder level.
- You must have the check out permission on the dependency folders to check out a bot with dependent folders and files.
- You must have the **Cancel checkout** and **View content** permissions on a public workspace to cancel or undo a check out performed by a Bot Creator user,

You do not require the **Cancel checkout** permission to cancel the checked out bot from a private workspace.

Checking out bots

You can check out single or multiple bots along with their dependencies. You can also choose the version of the bot and their dependencies during the check out.

- [Check out a single bot](#)
- [Check out multiple bots](#)
- [Check out file dependencies](#)

Check out a single bot

Check out the specific version of a parent bot and its dependencies from the public workspace to the private workspace to create an editable copy of the bot.

[Prerequisites for checking out bots and dependencies](#) on page 2213

1. Log in to the Control Room as a Bot Creator or a Citizen Developer user.
2. On the left pane, click **Automation**.
A list of available and forms is displayed.
3. Select the bot, choose to either clone or check out the dependencies, open the actions menu (vertical ellipsis) and click **Check out Task Bot**.

Note: If a bot has multiple versions, you can select and check out the specific version of the bot using **Advanced options**. This enables you to roll back to an earlier version of the bot.

Option	Steps
Yes, Checkout	Select this option to check out the latest version of a bot. The dependencies are cloned automatically.

Option	Steps
Advanced options	<p>Select this option to select a specific version of the parent bot and dependencies.</p> <ol style="list-style-type: none"> a) Click Advanced options. b) Select the version of the parent bot to check out. c) Add or remove dependencies to check out. d) Select the version of the dependency (bot or non- bot) to check out. e) Review the dependencies (Overwritten, Missing, Cloned, Skipped). f) Click Check out.

The bot appears in the same folder structure in the private workspace. When you check out bot files or folders, all the dependencies linked to the bot files or folders will either be checked out or cloned according to your choice.

4. To cancel the checked-out bot, click the **Cancel check out Task Bot** option.

You can use this option from either the public or the private workspace.

In the public workspace, the bot status changes to public, and the bot is available for check out by another user with the appropriate permissions.

In the private workspace, the bot status changes to new if any changes are made to the bot. If there are no changes, the bot is replaced with a clone.

Check out multiple bots

Check out the specific versions of the parent bots and its dependencies from the public workspace to the private workspace to create an editable copy of the bot.

Ensure you have completed all the prerequisites for checking out bots:

- [Prerequisites for checking out bots and dependencies](#) on page 2213
- Check out up to 10 parent bots at a time
- Check out only the latest version of the bot

1. Log in to the Control Room as a Bot Creator or a Citizen Developer user.
2. On the left pane, click **Automation**.
A list of available bots and forms is displayed.
3. Select the bots you want to check out and from the table level icons, click **Check out checked items**.

Note: You can check out up to 10 parent bots at a time. You can check out only the latest version of the bot and its dependencies.

Option	Steps
Check out	Select this option to check out the latest version of a bot. The dependencies are cloned automatically.
Advanced options	<p>Select this option to review the information about the bot and dependencies which can be checked out, skipped, cloned and click Check out.</p> <ul style="list-style-type: none"> • The Files tab displays the bot files that can be checked out. • The Checkout Dependencies tab displays the dependencies which you can choose to check out. • The Review dependencies tab displays the information on the dependencies which are Overwritten, Missing, Cloned, or Skipped.

The bot appears in the same folder structure in the private workspace. When you check out bot files or folders, all the dependencies linked to the bot files or folders will either be checked out, cloned, skipped, or overwritten. For more information, see [Considerations for checking out multiple bots](#) on page 2216.

Considerations for checking out multiple bots

There are certain considerations you have to keep in mind when checking out multiple bots.

- You can check out up to 10 parent bots at a time.
- You can only check out the latest version of the bot. You cannot select a specific version of the bot to check out.
- During check out of multiple bots, the parent bots and their dependencies are either checked out, cloned, skipped, or overwritten depending on different scenarios.

The following table explains the different scenarios of the parent bots and their dependency behavior during check out of multiple bots.

Scenario	Behavior
Parent bot not checked out by the current user	The parent bot is checked out as part of the bulk checkout and is shown in the check-out section of the basic flow.
Dependency not checked out by the current user	The dependency is checked out as part of the bulk check out and is shown in the check-out dependencies section of the advanced flow.
Parent bot is already checked out by the current user	The parent bot is not re-checked out and is shown in the skipped section of the basic flow.
Dependency already checked out by the current user	The dependency is not re-checked out and is shown in the skipped section of the advanced flow.
Dependency checked out by other users	The dependency is cloned during bulk check out.
Parent bot already cloned by the current user and requiring a check out	The parent bot is checked out as part of the bulk checkout, and the clone will be replaced with the checked out bot.

Scenario	Behavior
Dependency already cloned by the current user and requiring a check out	The dependency is checked out as part of the bulk checkout, and the clone will be replaced with the checked out bot.
Dependency already cloned by the current user and is shown again for cloning in bulk check out	The dependency is not re-cloned and is shown in the skipped section of the advanced flow.
Parent bot is in new status in private workspace	During bulk check-out, the user is provided an option to overwrite the bot in the basic flow.
Dependency is in new status in the private workspace	If the dependency is to be checked out, it is shown in the overwrite section of the advanced flow. If the dependency is to be cloned, it is shown in the cloned section of the advanced flow.

Clone a bot

Create a read-only copy of the bot from the public workspace to the private workspace so that you can have a local copy without checking out the bot.

- Create a user with a Bot Creator license.
- Create a custom role with the clone permission assigned at the folder level to the user.
- To clone a dependency folder, you must have the clone permission on the dependency folder.

Cloning a bot does not affect other users' access to the bot in the public workspace. A bot can be cloned by multiple users.

To edit a copy of the cloned bot in your private workspace, see [Edit a bot](#) on page 2222.

1. Log in to the Control Room as a Bot Creator user.
2. On the left pane, click **Automation**.
A list of available and forms is displayed.
3. Select the bot you want to clone, click the actions menu (vertical ellipsis), and click **Clone Task Bot**.

The cloned bot appears in the same folder structure in the private workspace.

Related tasks

[Edit a bot](#) on page 2222

Edit bot logic using the Bot editor to add, modify, or delete actions and automation steps.

Delete a bot

If you are a Control Room administrator or user with **Delete from Public** permission, you can delete bots from the public workspace. If you are a Bot Creator, you can delete bots from your private workspace.

To delete a bot, ensure the following:

- Public workspace: You must have the Control Room administrator role or the **Delete from Public** permission at the folder level.

- Dependent folders and files: You must have the **Delete from Public** permission on these folders and files.
- Private workspace: You must have a Bot Creator license.
- You cannot restore a deleted bot, so ensure that you no longer require a bot before deleting it.

Note: After you delete a bot, if you immediately create a bot with the same name as the deleted bot and create it in the same folder, an error is displayed in some cases. To avoid this error, after you delete a bot, wait for at least 5 seconds for the deletion to be completed. You can create another bot with the same name as the deleted bot and in the same folder.

- You cannot delete a bot if it is referenced by other bots. You must first remove the references before deleting the bot.

- Delete bots from a private workspace:

In a private workspace, you can delete only bots that are in the **New** or **Cloned** status. You cannot delete a bot in the **Checked out** or **Checked out and edited** status.

- Log in to the Control Room as a Bot Creator.
- On the left pane, click **Automation**.
A list is displayed with the available files and folders containing the bots.
- From the **Automation** page, choose one of the following methods to delete a bot:

Option	Action
Specific bot	<ol style="list-style-type: none"> Select the bot. Hover over the actions menu (vertical ellipsis) located to the right of the bot name and click Delete Task Bot. Click Yes, delete.
Multiple bots	<ol style="list-style-type: none"> Select the check boxes corresponding to the bots, and click Delete checked items. Click Yes, delete.

- Delete bots from a public workspace:

In the public workspace, you can delete only bots that are in the **Public** status. You cannot delete bots that are in the **Checked out** status.

- Log in to the Control Room as an administrator, a Bot Creator, or an attended or unattended Bot Runner user with **Delete from Public** permission.
- On the left pane, click **Automation**.
A list is displayed, with the available files and folders containing the bots.
- From the **Automation** page, choose one of following methods to delete a bot:

Option	Action
Specific bot	<p>a) Select the bot.</p> <p>b) Hover over the actions menu (vertical ellipsis) located to the right of the bot name and click Delete Task Bot.</p> <p>c) Click Yes, delete.</p>
Multiple bots	<p>a) Select the check boxes corresponding to the bots, and click Delete checked items.</p> <p>b) Click Yes, delete.</p>

Preload packages

You can preload packages on your local device to shorten the bot runtime.

When you run a bot, the system downloads the bot and all the packages used in the bot. Bot execution begins when the download is complete. If the packages used in the bot are preloaded, the system can skip downloading the packages and start executing the bot, thereby reducing the bot execution timeframe.

Folder path: Preloaded packages are stored in `\ProgramData\AutomationAnywhere\GlobalCache` on the local device.

If there are multiple versions of a package, only the default package is preloaded. You can only preload packages on your local device. For the option to be available, the automatically download preloaded packages setting must be enabled by the Control Room admin.

Note: You can also save specific versions of packages that are used in bots offline to save the time it takes to download these packages from the Control Room. The specific version of packages are stored in the `C:\ProgramData\AutomationAnywhere\AAPreloadedPackages` folder. You must create this folder manually `C:\ProgramData\AutomationAnywhere\AAPreloadedPackages`.

Perform the following steps to preload packages on your local device:

1. Log in with a Bot Creator account.
2. Click the **Manage > Devices > Preload package** icon in the menu list for your local device.

Note: The **Preload package** option is also available from the device icon drop-down menu for Automation 360 Cloud through the Google Chrome browser with the Chrome plug-in enabled.

3. In the **Preload packages** window, preload either all packages listed on the **Common packages** page, or select individual packages from the **Customize packages** page.

Common packages are the most lightweight and most commonly used ones.

4. Click the **Start preloading** option.

Copy a bot

Copy a bot to create a duplicate sequence of actions within your private repository. The copy retains the meta-data of the original bot including captured images, recorded objects, called files, and child bots.

To copy a bot, follow these steps:

1. On the left pane, click **Automation**.
A list of available and forms is displayed.
2. Mouse over the actions menu.
The actions menu is the vertical stack of three dots to the left of each bot.
3. Click the Copy Task Bot icon.
4. In the **Name** field, enter a name for the duplicate bot.

Important: Bot name must be unique. If a bot with the same name exists in the same folder location which you have access to in the public workspace, you will not be able to copy the bot with this name in the private workspace.

Consider the following naming conventions when copying bots:

- Ensure that a bot name does not end with a period (.) or space.
- Do not use bot names that are reserved for the Windows operating system. The reserved bot names are as follows:

CON	PRN	AUX	NUL	COM1
COM2	COM3	COM4	COM5	COM6
COM7	COM8	COM9	LPT1	LPT2
LPT3	LPT4	LPT5	LPT6	LPT7
LPT8	LPT9	--	--	--

- For more information about file naming, see [Microsoft guidelines](#).
5. Optional: Click **Browse** to select the folder where to save the bot.
 6. Click **Copy**.
The duplicate bot appears in the specified folder.

View Task Bot version history

View the history of the changes that have occurred in your Task Bots. You can identify actions performed by other users during a specific date and time along with check-in messages.

You must have either check-in or check-out permissions.

You can view the version history of the Task Bots available in the public workspace (only if there are checked-out bots). However, there is no version history available for new and the cloned Task Bots.

The check-in or the check-out permission is required for the Bot Runner to view the version history. However, note that this permission cannot be used by the Bot Runner to check in or check out bots.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.
A list of available and forms is displayed.
3. View the version history of Task Bots in the following ways:
 - Select the Task Bots for which you want to view version history. Hover over the actions menu (vertical ellipsis) located to the right of the Task Bots name and click **View history Task Bot**.
 - Click the bot name. When the bot opens, click the vertical ellipsis at the top-right corner and select the **View history Task Bot** option.

A message appears listing all the versions of the selected bot in a sequence (latest revision on the top and the first revision is at the end). The information includes the version number, check-in message, checked-in date and time, and checked-in by username.

Assign label to a bot

You can now assign a production label for a particular version of a bot. You can use this label to choose the version on which you want to perform certain bot operations. With the version of your choice, you can schedule, run, queue, export, and trigger bot development workflows.

- You must have a custom role with the **Label bots** permission.
 - You can apply labels only to the bots that are checked in to the public workspace.
1. Log in to the Control Room.
 2. On the left panel in the public workspace, click **Automation**.
A list of available bots and forms is displayed.
 3. Select a bot, hover over the Actions menu (vertical ellipsis) on the right of the bot name, and click **Label Task Bot**.
A list of available versions of the bot is displayed.
 4. Select the version of the bot to which you want to apply a label.
 5. Click the right arrow (→) to add your selection.
 6. Click **Apply Label**.
The label **Production** is now assigned to the bot.

Note: If the production label option is selected for the parent bot, the corresponding dependent bots with the production label are also automatically selected. If any of the dependent bots do not have the production label applied, the latest version of the bot is selected. However, if the dependent bot is called through **Task Bot > Run > Variable > Control Room path** option, always the latest version of the bot is selected even if the production label is applied to the bot.

Edit a bot

Edit bot logic using the Bot editor to add, modify, or delete actions and automation steps.

Create a user with a Bot Creator or Citizen Developer license.

Consider an automation example where a Message Box action is used. Perform the following steps to edit the task bot:

1. Log in to the Control Room as a Bot Creator user.
2. On the left pane, click **Automation**.
A list of available bots and forms is displayed.
3. Perform one of the following actions to edit a bot.
 - Click the required bot.
 - Click the actions menu (vertical ellipsis), and click **Edit Task Bot**.

The bot opens in the edit mode.

4. Click the Message Box action in the automation.
5. In the dialog box on the right, edit the required values for the **Message box** action such as:
 - a) In the **Enter the message box window title** field, enter `My edit to task bot`.
 - b) In the **Enter the message to display** field, enter `Bot Games`.
 - c) Edit value in the **Scrollbar after lines** field and **Close message box after** check box.

Note: The type and number of variables might vary based on the various actions used in an automation.

6. Click **Save**.

Compare bot versions

You can compare different versions of your bots and view any modifications in your workflows in both the public and the private workspaces.

Ensure you have the following permissions:

- **View my bots**
- **View content**
- **Check in** or **Check out**
- Public workspace
 - a) Log in to the Control Room as a Bot Creator or a Citizen Developer user.
 - b) Navigate to the public workspace.
 - c) On the left pane, click **Automation**.
A list of available bots and forms is displayed.
 - d) Select a bot, hover over the actions menu (vertical ellipsis) on the right of the bot name, and click **Compare versions**.

The compare version page appears with two versions of your bot. The left column shows the previous version of your bot, and the right column shows the newer version of your bot.

- e) Click the **Change version** icon to select and confirm the version of the bot that you want to compare on the left and right column.

You can review the two versions of your bot. The red highlights on the left column show the lines that are modified. The green or blue highlights on the right column show the lines that are added or changed. This view shows the bot versions by **Actions**.

Note: When you compare two versions of a bot, you might sometimes not observe any visible changes. This is because the bot version is modified as a result of changes in the underlying JSON file.

- f) Optional: Select **Variables, Triggers, Packages, or Dependencies** to compare your bot versions by these categories.
-

Note: The changes made to the immediate dependencies are displayed, and the dependencies are sorted in an alphabetical order.

- g) Optional: Select the **Swap versions** icon to swap between your two current versions.
- h) Click **Close** to exit the comparison view.

- Private workspace

- a) Log in to the Control Room as a Bot Creator or a Citizen Developer user.

- b) Navigate to the private workspace.

- c) On the left pane, click **Automation**.
A list of available bots and forms is displayed.

- d) Select a bot, hover over the actions menu (vertical ellipsis) on the right of the bot name, and click **Compare versions**.
The compare version page appears with the left column displaying the source checked-out version of the bot in the public workspace and the right column displaying the checked-out and edited bot in the private workspace.

- e) Click **Change version** to change the current bot version in the left column (**Public** version).
The **Select version to compare** page prompts you to select a new bot version.
-

Note: You cannot change version on the right column (**Private** version).

- f) Select and confirm the version of the bot that you want to compare on the left column. You can review the source and edited versions of your bot. The red highlights on the left column show the lines that are modified. The green or blue highlights on the right column show the lines that are added or changed. This view shows the bot versions by **Actions**.

- g) Optional: Select **Variables, Triggers, Packages, or Dependencies** to compare your bot versions by these categories.
-

Note: The changes made to the immediate dependencies are displayed, and the dependencies are sorted in an alphabetical order.

- h) Click **Close** to exit the comparison view.

View bot dependency map

You can now view the dependency map for your bot in both the public and private workspaces. The dependency map shows the immediate parent and child bots for any selected bot. With this information, you can gauge the impact of the change in a bot, use the bot effectively, maintain better bot code and reusability, and prevent conflicts.

Ensure that you have the **View content** permission.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.
A list of available bots and forms is displayed.
3. View the dependency map of the bots in the following ways:
 - Select the bot for which you want to view version history. Hover over the actions menu (vertical ellipsis) located to the right of the bot name and click **View dependencies and references**.
 - Click the bot name. When the bot opens, click the vertical ellipsis at the top-right corner and select **View dependencies and references**.
4. Toggle between the **Dependencies** and **References** tabs to view the immediate parent and child bots.
 - **Dependencies**: Displays the bots or files that the bot uses to run
 - **References**: Displays the bots or files that depend on the bot to run

Attach work item template to bot

Attach a work item template to a bot to use the bot in workload automation.

When you attach a work item template to a bot, you can use the variable **\$WorkItem\$** that contains the attributes for the required workload automation when you run the bot using the **Run bot with queue** option.

[Use Work Item variables](#) on page 2253

1. On the left pane, click **Automation**.
A list of available bots and forms is displayed.
2. Create or edit a Task Bot from the **Automation** page.
The Task Bot opens in edit mode.
3. Select the option **Work item template** from the menu at the top-right of the Workbench.
The list of **Work item templates** appears.
4. Select the template that best suits your workload automation requirement.
5. Click the right arrow to add the template.
The **Work item template attributes** are listed for the selected template.
6. Click **Save**.
7. Choose one of the following actions:

- Click **Close** to return to the **My bots** page.
- Click **Return to editor** to continue editing the Task Bot.

Note: When you attach a work item template to a bot, you must deploy the bot using the **Run bot with queue** option in the Bot editor. If you deploy the bot using the **Run bot now** or **Schedule bot** option, the bot execution fails.

Related concepts

[Workload management](#) on page 1931

The workload management module enables users to upload Microsoft Excel and CSV files to the Control Room so that it feeds the records from the files into the bot deployments.

Related tasks

[Use Work Item variables](#) on page 2253

You can use the Work Item variables to pass the Work Item attributes or values to the Task Bot from the Control Room when you run the bot with the option **Run bot with queue**.

Related reference

[Workload package](#) on page 3054

The Workload package enables you to insert work items in a queue for workload automation. It also enables data chaining between multiple queues. You can orchestrate multiple bots, and enable optimal device utilization through the queueing mechanism of workload management.

Packages available in Automation 360

Actions are grouped into version-specific packages. Bot Creators can select which package version to use for a specific bot.

Basic users can only view the packages available in the Control Room and the specific package details.

Bot Creators require the **AAE_Basic** permission to select specific packages to use within a bot.

Go to the **Manage > Packages** page to view all the packages in the Control Room.

Packages updated in Automation 360

Important: With every Automation 360 general availability (GA) release, new packages or new package versions are provided with the latest innovations and all the code and security fixes from the previous versions. You can view package updates, including the compatible Control Room and Bot Agent versions.

- For v.27 and later releases, there are release-specific page for details about package updates in these releases. Navigate to the specific [Automation 360 Release Notes](#) on page 16, expand the table of contents, and open the Packages updated in v.xx page for release-specific information.
 - For information about packages in previous releases, see the PDFs available here: [Automation 360 previous release versions](#).
-

List of packages in the Control Room

The following table provides information about the packages in the Control Room.

Package name	Description
Process Composer package on page 2777	Enables user to configure their bots to work on requests, tasks, and team members.
Active Directory package on page 2283	Automates Active Directory operations to manage users across a group or organization.
Analyze package on page 2310	Performs transactional analytics for the data that is logged by the variables when the bot runs.
Apigee action package on page 2311	Use the Apigee package to connect to an Apigee instance to run integrations and collaborate efficiently to function as one unit.
App Integration package on page 2321	Captures the user-specified window or area and extracts text from it.
Application package on page 2326	Opens an application or file
Boolean package on page 2343	Performs various operations on Boolean values
Bot migration package on page 2346	Migrates legacy (11.x and 10.x) bots to Automation 360 format. Also, converts legacy and Automation 360 bots to Microsoft Edge with IE mode.
Browser package on page 2348	Enables you to download files, find broken links, and open a website.
Clipboard package on page 2360	Automates tasks through the Windows clipboard such as copying a string value to the clipboard, copying a clipboard value to a string variable, and clearing the clipboard.
Comment package on page 2365	Inserts a user-specified comment to the bot logic.
Credential package on page 2361	Performs credential operations
CSV/TXT package on page 2362	Opens a CSV or text file, reads data from the file, and assigns the data to a Table variable.
Database package on page 2379	Connects to a database, starts a transaction, and manages the stored data.
Data Table package on page 2365	Performs various operations on the values of table variables.

Package name	Description
Datetime package on page 2397	Enables you to perform various operations on date/time values such as updating and comparing values in Datetime variables.
Delay package on page 2405	Enables you to add a timed delay to the logic.
Dictionary package on page 2406	Performs various operations on dictionary-type values.
DLL package on page 2411	Uses a .dll file as reference and calls functions from the bot.
Document Extraction package on page 2425	Extracts data from documents and downloads that data. This package is used for processing documents in Document Automation.
Email package on page 2431	Automates email-related tasks through EWS, Microsoft Outlook, and other email servers.
Email trigger	Runs a Task Bot when an email is received in a particular email account.
Error handler package on page 2466	Handles exceptions that a bot encounters and transfers control to other actions within that bot.
Excel advanced package on page 2479	Automates tasks performed with Microsoft Excel spreadsheets. Use this package when Microsoft Excel is installed on the device.
Excel basic package on page 2472	Automates spreadsheet tasks in xlsx workbooks when Microsoft Excel is not available on the device.
File package on page 2513	Automates various file-related operations
Folder package on page 2523	Automates folder-related operations
FTP / SFTP package on page 2530	Automates FTP/SFTP operations
Genesys package on page 2555	Automates the repetitive tasks related to onboarding and updating the details of contacts by using the actions in the Genesys package.
Google Calendar package on page 2587	Automate creating and deleting events on Google Calendar.
Google Drive package on page 2591	Automates tasks on files and folders on Google Drive.
Google Document AI package on page 2601	Extracts data from documents by using the Google Document AI capabilities of the Google Document AI package in your bots.
Google Sheets package on page 2603	Automates tasks involving cells, columns, rows, and sheets in Google Sheets.

Package name	Description
Hot keys	Triggers for hot key events
If package on page 2619	Controls the sequence of execution based on one or more conditions of a task.
Image Recognition package on page 2626	Searches for a user interface element in an application based on an image to automate a task in that application.
Interactive forms package on page 2633	Provides actions that handle exceptions encountered by a bot. All the actions performed by users on the interactive forms can be monitored to execute logic using subtasks.
Interface trigger	Starts the bot when the Select main event takes place on the trigger interface element. For example, a user clicks on a button.
IQ Bot package on page 2653	Uploads documents to and downloads them from an IQ Bot server.
IQ Bot Pre-processor package on page 2636	Extracts content from documents or process image files before they are sent to IQ Bot.
JavaScript package on page 2655	Opens and runs a JavaScript from a bot.
Json package on page 2657	Extracts the required information from a JSON text or file and uses the extracted values in bots.
Legacy AISense	Provides actions to perform legacy AISense operations.
Legacy Automation package on page 2660	Provides actions to perform legacy automation operations.
List package on page 2669	Performs various operations on a variable of the list data type.
Log To File package on page 2676	Creates a log file with data
Loop package on page 2679	Runs a sequence of actions repeatedly for a specific number of times or until a specific condition is met.
Message box package on page 2691	Shows a message box
Mouse package on page 2693	Simulates mouse actions
Number package on page 2697	Performs various operations on a number variable. A number variable holds numeric values, including integers and decimals.
OCR package on page 2699	Extracts text from images or applications
Microsoft 365 Calendar package on page 2706	Automates meeting-related tasks in Microsoft 365 Calendar.

Package name	Description
Microsoft 365 Excel package on page 2715	Automates tasks in the online version of Microsoft Excel.
Microsoft 365 OneDrive package on page 2733	Automates repetitive tasks in OneDrive application.
PDF package on page 2763	Automates various operations on a PDF file
PGP package on page 2772	Automatically encrypt and decrypt files for security.
Ping	Provides actions to perform ping operations.
Play Sound package on page 2775	Plays sound files before or after an action is executed in a bot.
Printer package on page 2775	Automates retrieving and setting the default printer and removing a printer from the list of available printers.
Process package on page 2786	Contains a request action that enables the Control Room user to use this action and configure their bots.
Process trigger	Starts the bot on process events.
Process Discovery	Use this package to perform object operations.
Prompt package on page 2787	Performs prompt operations such as entering a value, requesting a yes or no response, or selecting files or a folder.
Python Script package on page 2789	Enables Python Script functions in a task
Record package on page 2794	Performs various operations on record-type variables.
Recorder package on page 2798	Records interactions with UI elements such as click, read, and write.
REST Web Service package on page 2834	Use methods such as DELETE, GET, PATCH, POST, or PUT to send requests to and receive responses from an API.
Salesforce package on page 2846	Automate your Salesforce CRUD operations on records, execute SOQL, and upload/download attachments.
SAP package on page 2863	Automates tasks and processes on an SAP application.
SAP BAPI package on page 2876	Contains actions to automate tasks and processes using SAP Business Application Programming Interface (BAPI). BAPI is a standardized method that enables a third-party application to interact with an SAP system.

Package name	Description
Screen package on page 2884	Automates the process of capturing an area of an application window, entire screen, or active open window and saves it in a specified location in an image format.
Service package on page 2889	Automates operations in Windows and application services including starting, stopping, pausing, resuming, or retrieving the status of a service.
ServiceNow package on page 2891	Provides actions for ServiceNow Rest APIs.
Simulate keystrokes package on page 2941	Simulates keystrokes in different language characters.
SNMP package on page 2943	Automates network management tasks such as retrieving and modifying data, and sending notification messages.
SOAP Web Service package on page 2955	Provides action to call SOAP web services and parse XML response.
Step package on page 2956	Groups various actions together and runs them in a specific order. You can provide a relevant name for a step to identify the operation performed by the actions included in that step.
String package on page 2957	Performs operations such as comparing two strings, retrieving the string length, or converting a string to uppercase or lowercase.
System package on page 2976	Automates locking, logging off, restarting, and shutting down operations for a machine.
Task Bot package on page 2980	Manages running one or more child from a parent bot or with a third-party software using an API.
Terminal Emulator package on page 2988	Connects to and automate tasks on another machine. For example, run applications and access files on a different operating system.
Text file package on page 3005	Open a text file, reads data from the file, and saves it to a string variable.
Trigger loop package on page 3007	Runs a loop that can handle triggered events until stopped.
V11 Task Bot package on page 3019	Runs Task Bots from version 11.3.2 and later.
VBScript package on page 3023 VBScript package on page 3023	Enables VBScript functions in a task

Package name	Description
Wait package on page 3025	Adds a condition to wait for an application screen to change, or a separate window to open or close before proceeding to the next action.
Window package on page 3044	Automates tasks relating to a window
Window trigger	Starts the bot based on window action.
Workload package on page 3054	Enables you to insert work items in a queue for workload automation. It also enables data chaining between multiple queues. You can orchestrate multiple bots, and enable optimal device utilization through the queueing mechanism of workload management.
XML package on page 3056	Automates the processing of XML data generated from web services and cloud computing applications.

Select the package version used in your bot

As a Bot Creator you have the ability to select which package version to use for a set of actions within your bot.

You need to have **AAE_Basic** permission.

Tip: For existing bots, follow these steps to update to the default package.

1. Open or create a new bot from **Automation** page.
2. Click the vertical ellipses in the upper right corner, and select **Packages**.

Note: The packages used in the selected bot are highlighted.

3. Click the drop-down list to view which version of the package is currently used for this bot.
4. To change the package version to be used for this bot, select the package version to use from the drop-down list of available packages.
5. Click **Change version**.
6. Click **Save**.

Bot compatibility version

Bot compatibility version provides internal versioning for bot compilation and helps track different runtime behaviors for specific features. Compatibility version helps to maintain backward-compatibility when there are breaking changes (when you make changes in one part of the code that can cause potential issues in other areas).

Available compatibility versions

Bot compilation occurs on the device where the Control Room is located. Typically a Windows or Linux device is used based on the deployment model (Windows for On-Premises and Linux for Cloud).

Depending on your requirements, choose one of the following versions:

Version	Description
1	The bot file path is parsed at compilation time.
2	The bot file path is parsed at bot runtime depending on the device on which the bot is running. For example, the UNC (universal naming convention) path format is different for Windows and Linux. When you choose this version, a message is sent to the bot compiler to parse the file path during runtime instead of at compilation time.
3	The global value used in the parent bot is carried over to the child bot using a shared cache for the entire bot run which reduces the bot execution time.
4 (Default)	<ul style="list-style-type: none"> When automations containing parent and child bots fail, enhanced error messages display the error details from the child bot. Verifies whether a DLL session exists even if the session name is defined through a variable.

Set the bot compatibility version

As a Bot Creator, you can set the bot compatibility version in the private workspace.

1. Log in to the Control Room.
2. In the private workspace, select the bot for which you want to set the version.
The bot opens in edit mode.
3. From the actions menu (vertical ellipsis), select **Advanced settings**.
4. If the **Bot compatibility version** is set to **1**, **2**, or **3**, we recommend that you set it to **4** (default version) to enhance the bot performance. Ensure that the parent bot and all the child bots have the **Bot compatibility version** set to **4**.

Note: Each version includes new features in addition to those provided by the previous versions. By selecting the latest version 4, you will get the advantages of all the cumulative features of previous versions.

5. Optional: Select the **Enabled improved number support** check box in the **Advanced features** field.

This setting helps in accurate float number calculation (positive or negative whole number with a decimal point) for your new bots.

6. Return to the bot editor and save the bot.

Compatibility version for migrated bots

After migration from Enterprise 11 to Automation 360 and if you have removed the `AAApplicationPath` from the destination path, your bot might fail. For more information on how to resolve this issue, see [Migrated bots and compatibility versions](#).

Set automation priority for your bots

Set the automation priority of your bots to high, medium, or low so that higher-priority automations are processed first for deployment. This enables you to meet your business SLA (service-level agreement) for resource optimization.

- You must have a Bot Creator license.
- You must be assigned the **Set automation priority to high** permission.

You can set the automation priority when you create and edit a bot.

1. Log in to the Control Room as a Bot Creator user.
2. In the private workspace, select a bot for which you want to set the priority. The bot is opened in edit mode.
3. From the actions menu (vertical ellipsis), select **Advanced settings**.
4. Set the **Automation priority** to high, medium, or low based on your requirements. When bots are queued for a Bot Runner user, bots with higher priority are deployed before bots with lower priority. However, if a bot with lower priority is already running, bots with higher priority are deployed after the bot with lower priority completes running. The default permission is set to medium.
5. Return to the bot editor and save the bot.

Configure timeout for bot execution

Specify the amount of time the system must wait before terminating a bot that is unresponsive or is taking more time than expected to complete the task.

When a task times out, any downstream tasks (tasks in a queue) can run without any issues.

Timeout for a task is not applicable in the following scenarios:

- When a task is manually paused.
- If the task is run in Debug mode.
- If the task is called through the **Run** action of the Task Bot package.
- When the first task in a process is paused, additional tasks are canceled and the first task is resumed.

1. Log in to the Control Room.
2. On the left pane, click **Automation**. A list of available and forms is displayed.
3. Open the bot for which you want to set timeout.

4. Select **Advanced settings** from the actions menu (three vertical ellipsis) on the top-right.
5. In the **Time out** field, specify the amount of time you want the system to wait before canceling a bot.
By default, the value in the **Time out** field is set to zero (0) and the system waits till the bot completes execution.
6. Return to the Bot editor and save the changes to the bot.

Create and rename folders

Depending on the permission assigned to you, you can create or rename folder names and description in the private workspace and rename the folder description in the public workspace. This helps to organize your bots and files in the Control Room repository.

To create folders, you must have the following permissions:

- View my bots
- Create folders

To rename folders, you must have the following permissions:

- View my bots
- Rename folders

You can grant access privileges to other users to specific folders so that they can perform various bot operations on the bots contained in that folder. Keep the following considerations in mind while renaming your folder:

- You can rename your non-empty folders only in the private workspace.
- Ensure the following when you rename a folder:
 - It does not contain checked-out or cloned bots even at subfolder levels.
 - It does not contain more than 100 items including subfolders and files.

Consider the following naming conventions when creating and renaming folders:

- Ensure that a folder name does not end with a period (.) or space.
- Do not use folder names that are reserved for the Windows operating system. The reserved folder names are as follows:

CON	PRN	AUX	NUL	COM1
COM2	COM3	COM4	COM5	COM6
COM7	COM8	COM9	LPT1	LPT2
LPT3	LPT4	LPT5	LPT6	LPT7
LPT8	LPT9	--	--	--

- For more information about file naming, see [Microsoft guidelines](#).
- Create a folder
 - a) Navigate to **Automation > Folder**.
 - b) Click a folder in the **Folders** tree view to open it. For example, **Bots > Sample bots**.

- c) Click the icon to create subfolders in the **Folder** tab and provide an appropriate name.
 - d) Browse and choose the path where you want to save the folder.
 - e) Click **Create folder**.
The folder is added and can be viewed in the **Folders** tree view and in the **Files and folders** tab.

- Rename a folder in the private workspace
 - a) Navigate to **Automation > Folder**.
 - b) Click a folder in the **Folders** tree view to open it. For example, **Bots > Sample bots**.
 - c) In the **Files and folders** tab, hover over the folder that you want to rename and click **Edit folder** (pencil icon).
 - d) Provide an appropriate name and description and browse and choose the path to the location where you want to save the folder.
 - e) Click **Save changes**.

- Edit folder description in the public workspace
 - a) Navigate to **Automation > Folder**.
 - b) Click a folder in the **Folders** tree view to open it. For example, **Bots > Sample bots**.
 - c) In the **Files and folders** tab, hover over the folder that you want to rename and click **Edit folder** (pencil icon).
 - d) Enter a meaningful description and then browse to select the location where you want to save the folder.
 - e) Click **Save changes**.

Variables overview

Automation 360 offers a variety of variables, each designed to hold specific types of data and is intended for specific use. Use the topics below to learn more about each variable and how to use them.

Using variables

The following table describes how Automation 360 passes variable values between a parent and child bot when using different data types:

Data type	Example	Behavior
Primitive data type (stores a single value)	String, Number, or Boolean	You create a parent and a child bot using primitive data types and run the TaskBot. When the parent bot passes a variable to the child bot through input variables, and if you change the values of those variables in the child bot, the changes are not saved when execution returns to the parent bot. When you use primitive data types, the variable's actual value is passed, and any changes made to these variables in the child bot are not reflected in the parent bot.
Non-Primitive data type (stores multiple values)	List, Dictionary, or Record	You create a parent and child bot using non-primitive data types and run the TaskBot. When the parent bot passes a variable to the child bot through input variables, and if you change the values of those variables in the child bot, the changes are saved when execution returns to the parent bot. When you use the non-primitive data types, the values are passed by reference, and any changes made to these variables in the child bot are reflected in the parent bot.

Example: You created a parent and child bot using the following variables:

- VarList: `Employee data (First name, last name, Date of birth)`
- VarString: `Employment type (Permanent)`
- VarNumber: `100`

You used the same variables in the child bot with the **Use as input** check box selected.

In the child bot, you updated the following values:

- Added a new detail in the VarList variable as `Employee data (Date of Joining)`
- Changed the value of the VarString variable to `Employment type (Contract)`
- Changed the value of the VarNumber variable to `50`

When the parent bot calls the child bot, and the execution returns to the parent bot, the List variable will show the updated values, whereas the String and Number variable values will not change:

- VarList: Employee data (First name, Last name, Date of birth, Date of joining)
- VarString: Employment type (Permanent)
- VarNumber: 100

[Credentials and credential variables in the Bot editor](#) on page 2254

Use credentials when building bots to pass sensitive information such as passwords and account numbers. Using credentials separates the sensitive information from the bots and Bot Runners, which reduces the risk of data spillage or unauthorized user access.

[Predefined variables](#) on page 2237

Predefined (or system) variables return the specific values about the machine on which the bot is executed. Users cannot edit the values of a predefined variable.

[Your variables \(user-defined\)](#) on page 2241

Users and some actions create user-defined variables to temporarily hold values. Use this kind of variable to input values into an action (window title, login credential, or file path) or to accept the output of an action (values read from a file or a Boolean return).

[Create a variable](#) on page 2246

[Global values](#) on page 2260

Global values enable users to reuse identical values between bots instead of creating new variables for each bot. A user with the `AAE_admin` role configures a global value with a default value and can enable non-admin users to overwrite the value to use in their bots.

[Work Item variables](#)

You can use the Work Item variables to pass the Work Item attributes or values to the Task Bot from the Control Room when you run the bot with the option **Run bot with queue**.

Predefined variables

Predefined (or system) variables return the specific values about the machine on which the bot is executed. Users cannot edit the values of a predefined variable.

Predefined variable types include clipboard, date time, string and system settings and parameters.

Note: System variables are called as predefined variables in Automation 360.

Clipboard

Use the actions in the Clipboard package to perform operations on the clipboard variable. See [Clipboard package](#) on page 2360.

Variable	Description
Clipboard	Returns the contents of the clipboard.

Date time

Use the actions in the Datetime package to perform operations on the date time variables. [Datetime package](#) on page 2397

Variable	Description
Date	Returns the date including hours, minutes, and seconds. Note: Hours can be in 24-hour or AM/PM format depending on the machine configuration.
Day	Returns the day in DD format.
Hour	Returns the hours in HH format.
Machine	Returns the device name as a string.
Millisecond	Returns the milliseconds with a value between 0 and 999.
Minute	Returns the minutes in MM format.
Month	Returns the month in MM format. Note: This is a numeric type variable.
Second	Returns the seconds in SS format.
Year	Returns the year in YYYY format.

String

Use the following variables to change how a string is displayed.

Variable	Description
Enter	Starts a new line without returning to the beginning of the line based on the operating system of the device. For example, the variable always adds a new line in Linux CentOS. In Microsoft Windows, the variable adds a page break in the Microsoft Word application and a new line in the Notepad application.

Variable	Description
Newline	Starts a new line and moves the cursor to the beginning of the next line regardless of the application and operating system of the device.
Separator	Demarcates a separation between values with a <sep> value.
Tab	Creates large space.

System settings and parameters

Use the following variables to return data from the computer that is connected to the running Bot Agent:

Variable	Description
AAControlRoom	Returns the URL of the Control Room.
AAInstallationPath	Returns the Bot Agent installation path. For example, C:\Program Files\Automation Anywhere\Bot Agent.
AATaskExecutor	<p>Returns details on the Run-as user that is used to run a bot. If the bot is deployed on an attended Bot Runner, this variable returns information about the logged-in user. If the bot is deployed by a trigger, this variable returns information about the user associated with that Bot Runner license.</p> <p>This variable is a dictionary with the following keys:</p> <ul style="list-style-type: none"> • <code>Executor_UserName</code> • <code>Executor_FirstName</code> • <code>Executor_LastName</code> • <code>Executor_Email</code> • <code>Execution_type</code>: Returns the type of execution <ul style="list-style-type: none"> • When you schedule a bot to run, the <code>Execution_Type</code> key in the <code>AATaskExecutor</code> variable returns information about the execution type with the schedule type (frequency) such as Run as schedule <Daily, Weekly, or Monthly>. • When you use a trigger in a bot, the <code>Execution_Type</code> key can be accessed through the trigger data. The <code>Execution_Type</code> key returns the Run through Trigger as a string for triggers. The <code>Execution_type</code> can be used in all the triggers.

Variable	Description
AATaskInvoker	Returns details on the user that deployed the bot either by running or scheduling the bot. If the bot is deployed to an attended Bot Runner, this variable returns information about the logged-in user. If the bot is deployed by a trigger, this variable returns information about the user who set the trigger. This variable is a dictionary with the following keys: <ul style="list-style-type: none"> Invoker_Email Invoker_FirstName Invoker_UserName Invoker_LastName
AATaskName	Returns the path and name of the currently running Task Bot. For example, /Bots/Finance/combineSheets.atmx.
CPUUsage	Returns the percentage utilization of the CPU. Use this variable in a Wait for condition action to make the bot wait until machine CPU usage decreases to a specific amount. See Wait package on page 3025.
Machine	Returns the name of the computer.
RAMUsage	Returns the RAM usage in megabytes. Use this variable in a Wait for condition action to make the bot wait until machine RAM usage decreases to a specific amount. See Wait package on page 3025.
OSName	Returns the operating system. For example, Windows 10 64-bit.
TotalRAM	Returns the total amount of RAM available.

- Version 11.3 contained Email, File, and PDF system variables, which could hold a limited number of properties values. In Automation 360, an infinite amount of Email, File, and PDF properties values are stored in User-defined Dictionary variables. For more information, see [Using dictionary variable for email properties](#) on page 2461 and [Using a dictionary variable for PDF properties](#) on page 2772.
- Version 11.3 contained Excel system variables to return the cell, column, or row location. In Automation 360, the Excel Advanced package contains the following actions to return location values: [Get cell address](#), [Get column](#), and [Get row](#).
- Version 11.3 contained the Counter system variable to return the loop iteration count. In Automation 360, the user must create and configure a number variable.

Your variables (user-defined)

Users and some actions create user-defined variables to temporarily hold values. Use this kind of variable to input values into an action (window title, login credential, or file path) or to accept the output of an action (values read from a file or a Boolean return).

When you are building automated tasks, some actions need to refer to and use some values, and these values can be stored in variables. Variables can help you in several ways, from retrieving online data to transferring data between applications, such as Microsoft Excel. A variable can hold one or more values. The values that a variable can contain and the operations that can be performed on the variable are determined by its data type.

Note:

- A bot can return only a maximum of 3 MB to an output variable. In addition, the table structure in BotOutputVariable is limited to 300,000 cells.

If you insert more than 300,000 cells, an error message is displayed indicating that the debug variable is too big to debug or that BotOutputVariable is too big to process.

Workaround: Store the bot output on the device, such as in a .txt file. If the output must be shared across multiple Bot Runners, store the output in a shared drive.

- The size of bot input variables is limited to 1900000 bytes. We recommend you use .txt file to store large data set.
-

Variable types

The data type of a variable is an attribute that determines the kind of data that the value stored in the variable can have. Data types include storage classifications, such as integers, strings, and characters. Variables such as dictionary, record, list, or table can hold multiple data types.

Most variable types have a package with a similar name, which contains actions used to perform operations on the values stored in the variable. For example, use the actions in the String package to work on String variables. Similarly, to work on Number variables, use the actions in the Number package. To convert the value of one variable type to another, see [Type conversion](#) on page 2248

You can also reuse identical values between bots instead of creating new variables for each bot. See [Global values](#) on page 2260.

Variable naming

A variable name can contain a maximum of 50 Unicode characters, including numbers (0-9), Latin letters (A-Z, a-z), and special characters (- and _). You can use double-byte characters, such as Chinese, Japanese, or Korean characters, in a variable name. [Unicode blue supported in variables](#) on page 2251

We recommend using camel case for variable names and prefixing the variable name to indicate the scope and data type. For example, `iFileEmailAttachment` for a file type variable that is used to provide an input.

Note: The following is a recommended naming standard for variables `<type/scope indicator><data type><Variable name>`. While there are many naming convention options, some standards must be adopted and used consistently within the organization.

The `<type/scope indicator>` is a single character as follows:

- p = local variable (neither input nor output)
- i = input variable
- o = output variable
- io = input and output variable
- c = constant

Following are a few more examples for naming variables.

- `iStrAuditLogPath`: a string type variable received from a calling task
- `oNumReturnValue` : a number type variable returned to a calling task
- `ioStrStatus`: a string that is both received from and returned to a calling task
- `cStrNull`: a string that holds no value; for example, useful for string comparisons to check whether a value is present

For more information about scope, see [Task Bot package](#) on page 2980. This standard enables you to search for variables by type. For example, `oStr` returns variables that are used to hold output string values.

Variable types

Variable type and suggested name	Description	Use examples
Any Any	Stores Boolean, Data table, Datetime, File, Number, Record, String, or Window data types. Use this variable type when you are uncertain of which data type an action will output.	Example of using the Run action on page 3095
Boolean Bool	Stores either a True or False value.	
Credential Cred	Stores string values securely, preventing values from being displayed in a message box or written to a file. The value is either selected from the Credential Vault or is user-provided.	Credentials and credential variables in the Bot editor on page 2254

Variable type and suggested name	Description	Use examples
DateTime Date	Stores a value containing a single date and time value.	You can format the values by selecting a predefined format or specifying a custom format. Datetime formats on page 2402
Dictionary Dict	Stores data in the form of key-value pairs. The value can be boolean, number, or string. Dictionary package on page 2406	<ul style="list-style-type: none"> • Using dictionary variable for email properties on page 2461 • Using a dictionary variable for PDF properties on page 2772
File File	Stores a file path. Example of using a file variable on page 3137	
Form Form	Stores the value that was input into an interactive form field. Using interactive forms on page 3214	
List List	Stores a sequence of boolean, number, or string values. List package on page 2669	
Number Num	Stores numeric values, including integers and decimals. It holds values from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807, and up to 15 decimal digits. You can assign a randomly generated value to this variable. Random number action	You can remove the digits following a decimal when converting the value into a string. Number to string action
Record Rec	Stores a single row of values extracted from a table. The values can be boolean, datetime, number, or string. Record variable on page 2250	Example of entering data into a web form from a spreadsheet on page 3074

Variable type and suggested name	Description	Use examples
Session Sess	Stores the session name from the Excel basic, Excel advanced, or Terminal Emulator packages. Pass this variable from a parent to a child bot in the Task bot > Run action to enable the child bot to process the data in the file opened in the parent bot. Note: When initializing this variable in the child bot, select Use as input .	Example for sharing an Excel session between bots on page 2985
String Str	Stores alphanumeric and special characters, and empty values. It can hold up to 65535 UTF-8 characters. A string variable can hold multiple lines of text.	You can compare the value in a String variable to an empty String variable. Example of using a conditional statement on page 3078
Table Table	Stores multiple values in a table of rows and columns. The values can be boolean, datetime, number, or string.	Assign values to a table variable by extracting values from a CSV/TXT file , Excel file , or a Web form .
Window Win	Stores a window title and URL. When you create a Window type variable, note that selecting Browser as default value supports only Google Chrome tabs whereas selecting Application as default value supports any application window.	Some actions, such as the Capture action, create a Window variable to store the specified window title and URL. Example of extracting data from a web table on page 3071

How window variables behave

When you use the Recorder to automate a specific window, for example `window 1` and perform a **Click** action on the window, and run the bot, the bot for the first time searches that specific window and assigns a window handle to it for identification and saves it in cache. When you perform a second **Click** action on the same `window 1`, the bot verifies if the `window 1` is available. If the `window 1` is available, then the bot no longer must search for the specific window

as the window is already stored in cache and automatically fetches it from there. This enhances the performance of the bot and saves time as the bot does not have to search the window at every instance if the window is already available.

Suppose you now perform a third **Click** action on the same `window_1` that opens to another page because of which the window title has now changed. For example, you open a Yahoo

India web page and perform a **Click** action on the **News** option on the web page, the action navigates you to another page which changes the title of the window.

Hence in this case when you run the bot, the bot still fetches the same window that is stored in the cache and performs action on it because the window is still the same but only the title has changed. Hence this behaviour provides a good user experience, and you can avoid creating multiple window variables for each window whose title changes while automating web pages.

Delete variables

You can delete user-created variables in either of the following ways:

- Delete one variable: In the **Variables** palette, click the vertical ellipsis to the right of the variable name and click **Delete variable**.
- Delete unused variables: In the **Variables** palette, click **Delete unused variables**, select which variables to delete, and click **Delete**.

The **Boolean** package contains actions that enable you to do various operations on boolean values.

[Data Table package](#) on page 2365

The Data Table package contains actions that enable you to perform various operations on the values of table variables. Use these actions to join or merge content, search for specific values, insert rows and columns, remove duplicate rows, and write values to a file.

[Datetime package](#) on page 2397

A datetime value consists of a date, time, and time zone. Automation Workspace stores datetime values in a Datetime variable. The **Datetime** package contains actions that enable you to perform various operations on datetime values. You can use these actions to manipulate and compare values in the Datetime variables.

[Dictionary package](#) on page 2406

The **Dictionary** package contains actions that enable you to do various operations on dictionary-type values.

[List package](#) on page 2669

The **List** package contains actions that enable you to perform various operations on a variable of the list data type.

[Number package](#) on page 2697

The Number package contains actions that enable you to perform various operations on a number variable. A number variable holds numeric values, including integers and decimals. It holds

values from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807, and up to 15 decimal digits.

[String package](#) on page 2957

Use the `String` package to perform various operations such as comparing two strings, retrieving the string length, or converting a string to uppercase or lowercase.

[Type conversion](#) on page 2248

You can temporarily convert the values inside a Boolean, Number, or String variable from one type to another type (typecasting) to use within one action. For example, use `$(YourStringVariable).String:toNumber$` to convert the value of a string variable to a number variable to perform mathematical operations.

[Recursive expressions](#) on page 2249

Use a recursive expression to insert a variable in the place of an index or key of a dictionary, list, record, or table variable.

Create a variable

Create a variable to store values.

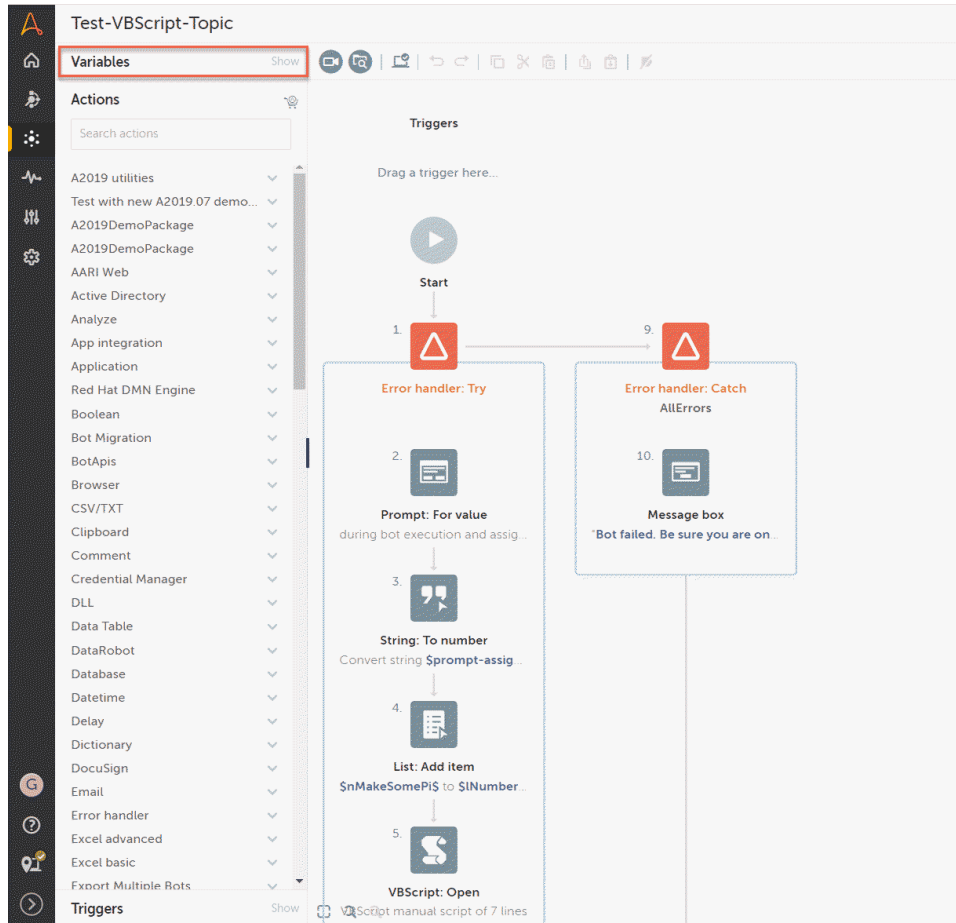

When you create a variable that uses characters such as the underscore (`_`) or hyphen (`-`) in your variable name, note that the underscore or hyphen are treated as the same character for the variable names. For example, `global-temp_path` is treated the same as `global_temp-path`. If you create a new variable that uses variables different from these two characters, an error is displayed.

If you have created a global variable as `global-temp-path`, you can refer to this variable in any of the following formats:

- `global-temp-path`
- `Global-Temp-Path`
- `global_temp_path`
- `Global_Temp_Path`

To create and configure a variable, perform the following steps:

1. From the Bot editor, click **Variables** > **Create variable** (+ icon) at the top of the **Variables** menu.

- In the **Create variable** window, enter a descriptive name for the variable that is prefixed by a lowercase letter to indicate the variable type.
For example, `sCe11Va1ue` to indicate a string data type.

Note:

- You can use double-byte characters, such as Chinese, Japanese, or Korean characters, in a variable name. [Unicode range supported in variables](#) on page 2251
- Variables cannot be named Java keywords, such as String, Boolean, Integer, Public, and Finally.

- Optional: Enter a description.

Recommendation: Provide meaningful variable description when defining input or output variables.

- Optional: Select the **Constant (read-only)** option to ensure values cannot be edited or overwritten.
- Select from the following options:
This field pertains to using a bot to run other bots. See [Task Bot package](#) on page 2980.
 - Use as input:** The variable holds a value that can be passed from the parent bot to a child bot. (Applicable only to a child bot)

- **Use as output:** The variable holds a value that can be passed from a child bot to the parent bot. (Applicable only to a child bot)
- **Both:** The value can be passed in both directions.
- **Neither:** The variable is confined to this bot; it cannot be shared across other bots.

The following example illustrates when to select **Use as input** or **Use as output** in a variable.

Suppose you want to add two numbers. The values are present in the parent bot, and the child bot performs the calculations. For the parent bot to transfer the values to the child bot, the two variables you created must be selected as **Use as input** so that the child bot can receive the values. Now, for the parent bot to receive the calculated value, the variable that stores the result of the calculation in the child bot has to be selected as **Use as output**.

Note: Ensure that you select the check boxes when you create a variable in the parent bot and the child bot. When you build the bot, and if you edit the selection of check boxes, it might impact your parent bot references, such as your parent bot might not work after this change.

6. Select a data type from the drop-down list.
For more information on data types, see [Variable types](#) on page 2241.
7. Optional: Enter a default value to assign to the variable.
The values are NULL/empty by default.
8. Click **Create**.
The variable appears in the Variables pane on the left side of the Bot editor.
If you want to edit a variable, you can change its name and value but not its data type.
9. To insert a variable into an action field, perform one of the following actions:
 - Click F2 to open the variables list.
 - Click the **Insert a value** icon, located on the right side of the field.
 - Enter the variable name. As you type, the field generates suggestions of existing variables.

Note: Add a dollar sign at the start and end of the variable. For example, `$myVariableName$`.

You can use the variable option and pass it as a parameter to open a file in packages such as XML, Excel basic, or Excel advanced. To open files with different extensions, use the variable option to assign the folder path, file name, and file extension. First, create a variable for the folder path, `$sFolder$`. Then, for the files in the folder path, create two variables, one for file name `$name$` and another for file extension `$extension$`. To open a file, combine the variables as a string, such as `$$sFolder$\$name$. $extension$`. For the extension to work with different file types and different open options, you can add conditional logic.

[Build a Go be Great bot](#) on page 3068: Follow the steps in this procedure for an example of how to create a variable and assign it to an action.

Type conversion

You can temporarily convert the values inside a Boolean, Number, or String variable from one type to another type (typecasting) to use within one action. For example, use

`$(YourStringVariable).String:toNumber$` to convert the value of a string variable to a number variable to perform mathematical operations.

In the text field, enter `$(variable name)$.` After you enter the period, the auto-fill suggests possible actions such as `toNumber`.

Variable type	Typcasting options
Boolean	<ul style="list-style-type: none"> • invert: Converts the Boolean value to the opposite value (True to False and False to True). • toNumber: Converts the Boolean value to a numeric value (True to 1 and False to 0). • toString: Converts the Boolean value to a string value.
Number	<ul style="list-style-type: none"> • decrement: Decreases the number value by one. • increment: Increases the number value by one. • toString: Converts the number value to a string value. <hr/> <p>Note: When you convert a number value to a string value and if the number has a decimal value, the decimal value is removed after conversion. For example, 15.234 will be shown as 15 when you convert it.</p> <hr/>
String	<ul style="list-style-type: none"> • length: Returns the number of characters in the string as a numeric value. • lowercase: Converts the characters in the string to lowercase. • reverse: Reverses the characters in the string. • toBoolean: Converts the string value to a Boolean value. • toNumber: Converts the string value to a number value. The limits of the String to Number action apply here. <p>See String to number action .</p> <ul style="list-style-type: none"> • trim: Trims blanks and whitespaces from the string. • uppercase: Converts the characters in the string to uppercase.

Note: Type casting is not supported for the following scenarios:

- As a value that is passed between bots.
- As a property value for an object captured with the Universal Recorder.

[Object properties](#) on page 2801

Recursive expressions

Use a recursive expression to insert a variable in the place of an index or key of a dictionary, list, record, or table variable.

A recursive expression contains a variable nested inside of another variable (the outer variable). The value of the outer variable is conditional based on the value of the nested variable.

For example, the list variable `$listOfPlanets$` has the following values: Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, and Neptune. The Number variable `$indexPosition$` has value of 2. The expression `$listOfPlanets[$indexPosition]$` returns `Earth`.

The following types of expressions are supported. You can create a recursive expression containing up to 10 expressions.

- `$dictionaryVariable{$key}$`
- `$listVariable[$index]$`
- `$recordVariable[$index]$`
- `$tableVariable[$rowIndex][$columnIndexOrName]$`

Note:

- You cannot use a Table variable within a List variable. For example, the following expression is not supported: `$vListStr[$vTable[0][0]$]`
 - You cannot combine expressions with properties. For example, the following expression is not supported: `$dictionaryVar{$listStrVar[2]$}.String:reverse$`
-

Record variable

A record variable holds a row of data extracted from a database, spreadsheet, or table in name-field pairs. The fields can store values of Boolean, datetime, number, or string data type.

Working with a record variable

Record variables are commonly used in the loop action to store a single row of retrieved data; you can access a single value by specifying the index number or name. The index number is the position of the name-field pair. The name is either configured when the variable is initialized or it can be extracted from the column headers of the source table.

The following is an example table:

CustomerName	City
Dana	Pittsburgh
Sam	Los Angeles
Alex	Boston

In this example, a bot loops through the preceding table and assigns each row to `rCurrentRow`. To retrieve the value from the first column of each row, use either the index number `$rCurrentRow[0]$` or name `$rCurrentRow{CustomerName}$`.

Note: To retrieve a date time value from a record variable and use it as a string, concatenate the record variable with a string value in the action field.

Schema

A schema is like a template for the record fields. It sets the order of the fields and the type of data that can be entered into each field.

If you select the **Set schema** option when creating a new record variable, the following conditions apply at runtime, where the bot retrieves a row of data and stores it to a record variable:

- The retrieved values must match the configured field data types.

For example, the data set [{"name": "Sally"}, {"id": 002}, {"dob": "03/05/1989"}] can be assigned to a record variable with the schema [{"name": String}, {"id": Number}, {"dob": Date}].

- The data set attributes must follow the same order and capitalization.

For example, the data set [{"name": "Henry"}, {"id": 003}, {"dob": "06/13/2001"}] cannot be assigned to a record variable with the schema [{"id": Number}, {"name": String}, {"dob": Date}] or [{"Name": String}, [{"ID": Number}, {"DOB": Date}].

- The record variable can accept a superset of the configured fields if the fields are in the same order.

For example, the data set [{"name": "Alex"}, {"id": 004}, {"dob": "12/10/1995"}, {"pet": "yes"}] can be assigned to a record variable with the schema [{"name": String}, {"id": Number}, {"dob": Date}].

- The record variable does not accept a subset of data.

For example, the data set [{"id": 005}, {"dob": "05/21/1975"}] cannot be assigned to a record variable with the schema [{"name": String}, {"id": Number}, {"dob": Date}].

If the bot encounters a row of data that does not meet the record variable schema, the bot fails. This prevents the bot from passing incorrect or invalid data into the next action.

Use Work Item variables

You can use the Work Item variables to pass the Work Item attributes or values to the Task Bot from the Control Room when you run the bot with the option **Run bot with queue**.

The Work Item variables are available in a Task Bot only after you attach a work item template to the Task Bot when you define the work item template in the work item structure during queue creation.

[Attach work item template to bot](#) on page 2224

1. On the left pane, click **Automation**.
A list of available and forms is displayed.
2. Click **Create a bot**.
3. In the **Create a Taskbot** window, enter the required parameters such as **Name**, **Description**, and **Folder** location.
4. Click **Create & edit** to open the Task Bot in edit mode.
5. Attach the bot to a queue category by selecting a **Work item template**.
[Attach work item template to bot](#) on page 2224
6. Press the function key F2 to open the **Insert a variable** window and add the following Workload variables to an action:
 - a) **workItem** to view the default values or attributes of the Work Item when you run the Task Bot using the **Run bot with queue** option.
The **workItem** is an input variable for debugging a Workload bot to be used for Task Bot deployment options **Run now** and **Schedule a bot**. You can add the values for the **workItem** variable when you create an automation.

On the other hand, when you use the option **Run bot with queue**, the **workItem** variable uses the values passed on by the Control Room.

- b) workItemResult** to set the final outcome of the Work Item when you run the Task Bot using the **Run bot with queue** option.

Use the **String > Assign action** to set the value of **workItemResult** variable. This is an output variable type and you can use the string values as well as other variables to set the value of **workItemResult** variables.

The variables are read-only and therefore cannot be edited or deleted from the Task Bot editor page.

Double click a variable in the **Variables** panel to view the variable parameters:

- Variable name.
- Description of the variable.
- Read only if the Constant check box is selected when the variable was created.
- To be used as input or output parameter in a Task Bot during run time.
- Variable type.
- The default values or attributes that are configured with the Work Item template for a **workItem** variable or the default output values for a **workItemResult** variable.

Define the Work Item structure for processing in a queue. This enables you to manually upload the Work Items from the system in the absence of ready data in a file.

[Attach work item template to bot](#) on page 2224

Attach a work item template to a bot to use the bot in workload automation.

Related reference

[Workload package](#) on page 3054

The Workload package enables you to insert work items in a queue for workload automation. It also enables data chaining between multiple queues. You can orchestrate multiple bots, and enable optimal device utilization through the queueing mechanism of workload management.

Credentials and credential variables in the Bot editor

Use credentials when building bots to pass sensitive information such as passwords and account numbers. Using credentials separates the sensitive information from the bots and Bot Runners, which reduces the risk of data spillage or unauthorized user access.

Credential

A credential holds the sensitive information in attributes. An attribute can have a value that is standard for all users or it can accept a user-input value. For example, an `Email` credential can hold three attributes: `host name` (standard value), `username` (user input), and `password` (user input).

	<p>Credentials are predefined in the CREDENTIALS tab and cannot be modified when the user is building or running a bot.</p> <p>By default, all users can create, manage, and use their own credentials. A user is granted access to another user's credentials by receiving access to a locker that holds the credential. If the credential requires a user-input value, it appears in the CREDENTIAL REQUESTS tab.</p> <p>A credential must be assigned to a locker to be used for building and running a bot.</p>
Locker	<p>A locker specifies which users can view, modify, or access the credentials. For example, a human resources (HR) locker can hold <code>Email</code>, <code>Database</code>, and <code>Training website</code> credentials and allow only specific employees of the HR department to use the credentials in their bots.</p>
Credential variable	<p>A credential variable stores a credential value in a user-defined variable. It enables users to securely pass values to a bot and from a bot to another bot. Using a credential variable ensures that the values are not displayed in a message box or written to a file. The value is either selected from the Credential Vault or is provided by the user. You can use it into any action field that accepts a variable.</p>

Note: Values of this data type cannot be converted to another data type.

You can:

- Pass login credentials to a child bot.
- Retrieve confidential data, such as account numbers, and pass them to the main bot.

Note: You cannot pass credential values to the main bot when you deploy it from the **Run bot now** page. The values must be hard-coded in the bot or selected from the Credential Vault.

Working with credentials

- Only fields with a **Credential** tab below the field name accept a credential.
- Action fields display the locker, credential, and attribute name; users can not see attribute values in the Bot editor.

- A credential cannot be appended to other variables or to a string.

Packages that support Credential Variables

The following list of packages support use of credential variables:

- Active Directory
- Apigee
- Credentials
- Database
- Email
- Email trigger
- Excel advanced
- FTP / SFTP
- Generative AI
- Genesys
- Google G Suite
- Google Calendar
- Google Drive
- Google Document AI
- Google Sheets
- Interactive forms
- Legacy Automation
- Microsoft 365 Calendar
- Microsoft 365 Excel
- Microsoft 365 OneDrive
- Microsoft 365 Outlook
- Microsoft 365 Outlook trigger
- PDF
- PGP
- Recorder
- REST Web Service
- Salesforce
- SAP
- ServiceNow
- SharePoint
- Simulate keystrokes
- SNMP
- SOAP Web Service
- Terminal Emulator
- Workday

Example of building a bot that uses credentials

Build a bot that securely logs in to an online bank using credentials from Credential Vault, ensuring that the username or password is not stored in the bot or on the device.

- Credentials must be assigned to a locker to be used in a bot.
- You must have **Consumer** permissions to the locker.

If the email notification setting is enabled, you receive an email that confirms the locker name and your permissions to that locker.

In this example, you configure a credential with user-provided values and build a bot to automate logging into an online bank website.

1. Provide the user-input values.
 - a) Navigate to **BOTS > Credentials > CREDENTIAL REQUESTS**.
The credentials that require a user-provided value have an incomplete icon in the first column.
 - b) Click the credential that holds the bank login credentials.
 - c) Click **Edit**.
 - d) Enter the attribute values for the username and password and click **Save changes**.
2. Open a new bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create new > Bot**.
 - c) Enter a bot name and click **Create and edit**.
3. Open the browser to the bank login page.
 - a) Double-click or drag the **Browser > Open** action.
 - b) Enter the URL.
For example, `www.examplebank.com/login`.
Use an application page where you want to enter a credential.
 - c) Select your preferred browser.
 - d) Click **Save** and **Run**.
The bank website opens in a new window. If the website opens in a new tab, drag it into a separate window.
4. Specify the username text box.
 - a) Double-click or drag the **Recorder > Capture** action.
 - b) From the **Object detail** menu, select the window containing the bank website.
 - c) Click **Capture object**.
The window containing the bank website is activated.
 - d) Hover over the username text box and click when a red outline appears.
 - e) In the Object properties table, verify that the Control Type is a textbox.

- f) From the **Action** menu, select **Set text**.
 - g) Select the **Select a credential** option and click **Pick** to navigate to the credential. The **Pick a credential** window appears.
 - h) Select the **Locker**, **Credential**, and **Attribute** for the bank website username and click **Confirm**.
5. Repeat Step 4 to specify the password text box.
6. Specify the Log on button.
 - a) Double-click or drag the **Recorder > Capture** action.
 - b) From the **Object detail** menu, select the window containing the bank website.
 - c) Click **Capture object**.
The window containing the bank website is activated.
 - d) Hover over the Log on button and click when a red outline appears.
 - e) In the Object properties table, verify that the Control Type is a button.
 - f) From the **Action** menu, select **Click**.
7. Close the window containing the bank website.
8. Click **Save** and **Run**.

[Example of building a bot that uses credential variables](#) on page 2258

Perform the steps in this task to learn how to pass values securely between bots.

Related reference

[Recorder package](#) on page 2798

Recorder package captures a series of tasks in a process and then automates them. You can automate your business applications (for example, desktop, Web, SAP, and Java applications) using the Recorder to capture actions performed on application objects such as a text box, button, table, radio button, combo box, and list view.

[Credentials and credential variables in the Bot editor](#) on page 2254

Use credentials when building bots to pass sensitive information such as passwords and account numbers. Using credentials separates the sensitive information from the bots and Bot Runners, which reduces the risk of data spillage or unauthorized user access.

Example of building a bot that uses credential variables

Securely pass values to a bot using credential variables to automate the process of logging in to a bank website.

Complete the steps in the following task to build the child bot that automates logging in to a bank website: [Example of building a bot that uses credentials](#) on page 2257

This task is performed by the user who wants to build and deploy . You must have the necessary rights and permissions to complete this task, and authorization to log in to the as the licensed user.

In this example, you modify the bot to accept credentials passed from a parent bot.

In the bot that you built for [Example of building a bot that uses credentials](#) on page 2257, create two credential variables and insert them into the **Recorder > Capture** actions.

1. Configure the credential variable to hold the username.

Field	Input
Name	username
Use as input	select
Type	Credential
Default value	Insecure string, leave field empty

2. Configure the credential variable to hold the password.

Field	Input
Name	password
Use as input	select
Type	Credential
Default value	Insecure string, leave field empty

3. Modify the first **Recorder > Capture** action.
- Click the action to open it in the action editor.
 - In the **Select a credential** field, select the **Variable** tab.
 - Click F2 to open the Variables menu and select `$username$`.
 - Click **Yes, insert**.
4. Repeat the substeps in step 3 to insert the `$password$` variable into the second **Recorder > Capture**.
5. Click **Save** and **Close**
The **Automation** page appears.

Create a parent bot that will run the child bot and pass it the credential values.

6. Open a new bot.
- Click **Create new > Bot**.
 - Enter a bot name and click **Create and edit**.
7. Insert a **Task Bot > Run** action to select the bot and provide the login credentials.
- Double-click or drag the **Task Bot > Run** action.
 - In the **Task Bot to run** field, select the **Control Room file** tab.
 - Click **Browse** and select the bot that you modified in the above steps.
 - In the **Input values** options, select both **Set username** and **Set password**.
 - For each credential variable, click **Pick** to select the locker, credential, and attribute.
8. Click **Save** and **Run**.

Related reference

[Task Bot package](#) on page 2980

Use the **Run**, **Pause**, and **Stop** actions in the Task Bot package to manage running one or more child bots from a parent bot or with a third-party software using an API.

[Credentials and credential variables in the Bot editor](#) on page 2254

Use credentials when building bots to pass sensitive information such as passwords and account numbers. Using credentials separates the sensitive information from the bots and Bot Runners, which reduces the risk of data spillage or unauthorized user access.

Global values

Global values enable users to reuse identical values between bots instead of creating new variables for each bot. A user with the **AAE_admin** role configures a global value with a default value and can enable non-admin users to overwrite the value to use in their bots.

Data types

Data type	Description
DateTime	Stores a value containing a single date and time value.
Number	Stores numeric values, including integers and decimals. It can hold up to 15 decimal digits.
String	Stores alphanumeric and character values.
Boolean	Stores a Boolean value as True or False, default value is False. Note: The Boolean does not show the associated value or input when the user clicks View details on the Global values page.
User group	Stores the value of a user group either through the entities roles or teams.

Working with global values

Note: The maximum number of public global values that can be created by an admin user is 150.

Users can perform the following tasks:

- Create a global value as an admin.
[Create a global value](#) on page 2261
- Update the default value as a non-admin.
[Overwrite the default value](#) on page 2262
- Delete a global value.

A user with the **AAE_Admin** role can delete a global value by hovering over the vertical ellipsis to the right of the value, and clicking the **Delete** icon. When a global value is deleted, any overridden values for that global value are also deleted.

- Insert global values into bots.

All action fields that accept a user-created variable accept a global value. Insert a global value into an action field by pressing F2 or by clicking the **Insert a value** icon on the left side of the field.

Create a global value

You should have the `AAE_Admin` role to create a global value, configure the data type, set the default value, and enable the value to be updated by non-admin users

1. Log in as an administrator and navigate to **Manage > Global values**. The **All global values** page appears with a table of global values.
2. Click **Create global value**.

The **Create global values** screen appears.

3. Enter a descriptive name of up to 50 characters.

The screenshot shows the 'Create global value' form in the Automation Anywhere interface. The form includes a sidebar with navigation options: Manage, Scheduled, Event triggers, Devices, Queues, Global values (highlighted with a red circle 1), Credentials, and Packages. The main form area contains the following fields and options:

- Name:** A text input field containing 'NewGlobalValue' (circled with a red 3). Below it, 'Max characters = 50' is displayed.
- Description (optional):** A text input field containing 'This is a string global value' (circled with a red 4). Below it, 'Max characters = 255' is displayed.
- Type:** A dropdown menu showing 'String' (circled with a red 5).
- Value:** A text input field containing 'Test for Global Value of String Type' (circled with a red 6).
- The scope of this global value:** Two radio button options:
 - CANNOT be changed** (selected, circled with a red 7): The default value will be used for everyone.
 - CAN be changed**: The default value will be used, unless the username running the bot has changed the value.
- Buttons:** 'Cancel' and 'Create global value' (circled with a red 8).

Note:

- When the global value is initialized, you cannot change the name.
- Global values cannot be named Java keywords such as String, Boolean, Integer, Public, and Finally.

4. Optional: Enter a description of up to 255 characters.
5. Select the data type from the drop-down list.

[Data types](#) on page 2260

- User group: Select from Role or Team tab.
 - Role: Select the role that the users are assigned to.
 - Team: Select the team that the users belong to.

Note: When configuring the user group type value, teams must already be created to populate in the menu for selection.

- Basic data types (String, Number, DateTime, Boolean): Enter the default value.
-

Note: When the value is initialized, you cannot change the type.

6. Specify whether users can overwrite the value:
 - **CANNOT be changed:** The default value remains constant across all users and bots.
 - **CAN be changed:** Users can overwrite the default value to use in their bots.
-

Note: When you create a global value, if you set its scope to **CANNOT be changed**, you cannot edit the scope to **CAN be changed** later. If you want the scope of the global value to be **CAN be changed**, delete the value and recreate it with the scope set to **CAN be changed**.

7. Click **Create global value**.

Overwrite the default value

Global values can be configured to allow non-admin users to overwrite the default value. When building bots, use a global value for values that remain constant across all bots instead of creating a new variable for every bot.

As a non-admin user, you can only overwrite the default value in global values with a changeable scope. You can identify which global values have a changeable scope by checking the value in the **Scope changeable** column in the **All global values** table.

To verify if a global value has a changeable scope and to overwrite the default value, do the following steps:

1. Navigate to **BOTS > Global values**.
The **All global values** table appears. Each row shows the data type, value name, whether the scope is changeable, and the last modified date and time.
 2. Find the global value that has a changeable scope.
 3. Move your mouse over the vertical ellipsis and click **Edit global value**.
The **Edit global value** page appears with the **User value** field enabled.
 4. Enter the value that will overwrite the default value.
-

Note: This value will overwrite the default value of this global value in all of your bots.

5. Click **Save changes**.

Debug tool

The Debug tool helps you identify and troubleshoot any issues during bot running process. It improves developer productivity and helps narrow down the automation issues.

You can change or edit variable values in debug mode to run the automation successfully.

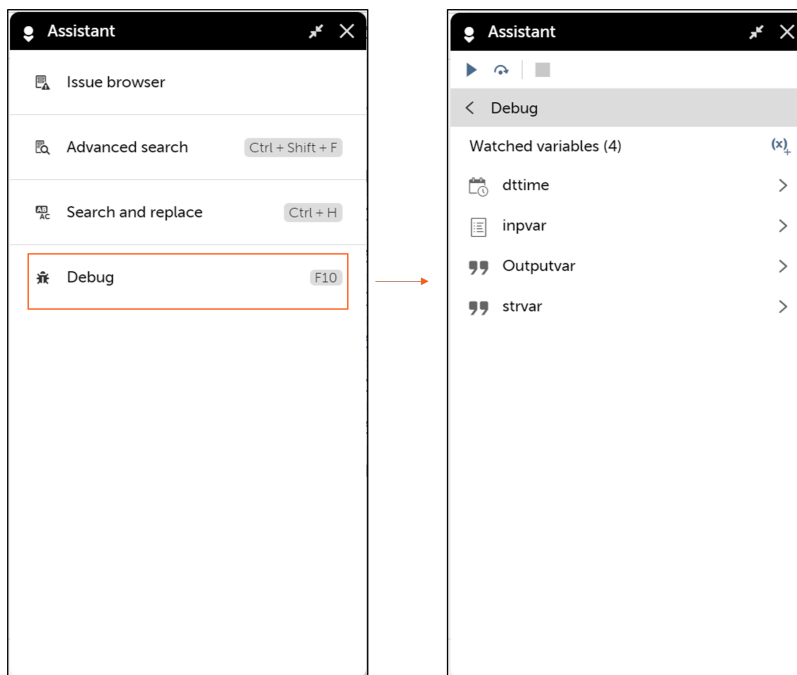

User role: Citizen developers and Professional developers

Debugging your automations

You can use the **Debug** tool in the Bot editor to debug your automations.

Using the Debug tool

From the **Automation** page, select and edit the bot that you want to debug. You can access the **Debug** tool from the **Assistant** utility or from the Bot editor.

When you invoke the **Debug** tool from the Bot editor:

- You can add, update, or delete actions and variables within a bot. You can continue to edit the bot as long as the debugging process has not yet started.
- A header bar appears below the bot name that displays the name of the bot being debugged. The header bar displays **Now debugging** and the bot name afterward. For example: **Now debugging: MSGBot5**
- The **Actions** panel on the left side of the Bot editor automatically collapses. This helps in providing more horizontal area to view the actions added in the Bot editor while debugging. Once the debugging stops, the **Actions** panel expands again.

Note:

- Invoking a debugger does not start debugging.
- Before you start debugging, ensure that you fix validation any errors in your bots.

- You can debug the bot in **Flow** and **List** views. However, for better visibility of your actions, we recommend that you debug your bot in the **List** view.

Debug controls

Actions	Icons	Keyboard shortcuts	Description
Start debugging		--	Use Start debugging to start the debugging process.
Step to next action		F6	Use Step to next action to debug one action at a time. After you have debugged the current action, you can use Step to next action to move to the next action in the sequence.
Continue to next breakpoint		F5	Use Continue to next breakpoint to move to the next breakpoint directly. Continue to next breakpoint executes the current action and then moves to the next breakpoint and pauses. Note: When debugging is in progress, the Start debugging icon changes to Continue to next breakpoint .
Stop		F7	Use Stop to stop the debugging process.

Adding breakpoints

Breakpoints allow you to pause the debugging process during a bot run. To pause and troubleshoot a specific action, you can insert a breakpoint at that specific action. When you enable the breakpoint, the specific action that is being debugged is highlighted with a pause

sign against it. After you add the breakpoint to pause the debug tool, you can **Continue to next breakpoint**, **Step to next action**, or **Stop** the debugging process.

Actions	Icons and keyboard shortcuts	Description
Enable breakpoint	 F9	<p>To insert a breakpoint, click the vertical ellipses on the specific code line and select Enable breakpoint.</p> <p>Alternatively, you can also enable a breakpoint by clicking on the specific line number. This displays a breakpoint icon on top of the line number.</p> <hr/> <p>Note: When you enable a breakpoint for a specific line of code, the Debug tool highlights it and denotes it with a pause button at the right side of the code line.</p>
Disable breakpoint	 F9	<p>To disable a breakpoint, click the vertical ellipses on the specific code line and select Disable breakpoint. The breakpoint becomes inactive. Additionally, you can also click the breakpoint icon on top of the specific line number to disable it.</p>
Clear all breakpoints	 Shift + F9	<p>To clear all breakpoints, click the Clear all breakpoints icon.</p>

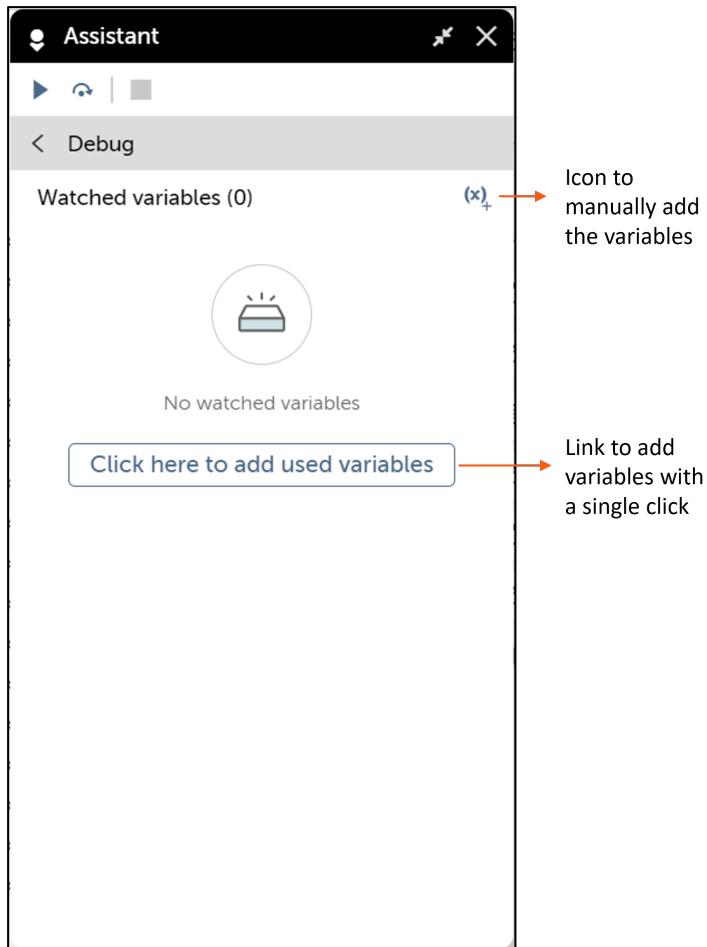

Watched variables

You can use **Watched variables** to watch the values of the specific variable during bot execution. By default, the **Watched variables** list is empty. With a single click, you can add used variables in a bot. These variables are displayed in a pop-up where you can select or deselect, one or more variables, from the list.

Adding watched variables

You can add variables used in a bot to the **Watched variables** list using either of these methods:

- Select the **Click here to add used variables** link in the **Assistant** utility pane to add all of the used variables in a bot with one click.
- Click the x () icon next to **Watched variables** to add or remove variables manually.

When a bot updates the variables, the values of those variables are updated dynamically in the **Watched variables** list. This provides a current status of a bot run at each action, and helps fix any bot-related errors early on from the **Debug** tool.

Note: If you rename a variable that is in the **Watched variables** list, then you must re-add it for it to display in the **Watched Variables** list.

Editing watched variables

To edit the variables added to the **Watched variables** list:

1. In the **Watched variables** list, click the variable that you want to edit.
A view with the specific variable details opens in the same tab.
2. Click the edit icon next to the variable name.

3. Change the value of the variable and click **Update**.

Note:

- To edit the watched variables, ensure that you install Bot Agent version 21.250 (which was released with Automation 360 v.29) on your system.
- You cannot edit the values of the constant variables.
- You can edit a variable value only when paused at a breakpoint in debug mode.
- The variable value that you update in debug mode is effective only during the debug session. It does not change the original variable value. Once the variable value is updated, the next set of actions that refers to the variable will use the new value.

Instead of navigating to the **Variable** panel, the **Watched variables** detailed view provides a quick reference of the variable properties such as type, input, output, and constant.

Currently, you can edit the values of the following variable types:

- Number
- String
- Boolean
- Datetime

You can navigate to the next and the previous variables from the edit window by clicking the next and previous arrows, respectively.

**Note:**

- You can watch variable values only when you start the debugging process.
- You cannot debug child bots from their parent bot.

Bot dependencies

Bots dependencies are files and other bots that are required to run that bot successfully.

Add bot dependencies

You must add the files that are required to run a bot as its dependencies.

Ensure that the files you want to add as dependencies are uploaded in the Control Room, except for bots.

The system identifies the automatic dependencies for a bot and adds the required files and other bots as its dependencies. However, for manual dependencies, you must identify the files and bots that are required and add them as dependencies for a bot.

1. On the left pane, click **Automation**.
A list of available and forms is displayed.
2. In the **PRIVATE** tab, expand the **Bots** folder that contains the bot for which you want to add dependencies.
3. Select the bot for which you want to add dependencies.
4. Select the **Edit Task Bot** icon from the actions menu (vertical ellipsis) on the right.
5. Select **Dependencies** from the actions menu (vertical ellipsis) on the top-right.
6. Expand the **Bots** folder and select the folder that contains the files you want to add as dependencies.
7. Select the files you want to add as dependencies from the Available files section and click the right arrow.
8. Click **Save**.
9. Click **Return to editor** if you want to update the bot or click **Close** to close the bot.

Related tasks

You can upload Enterprise 11 or Enterprise 10 bots, their dependent bots, and other files that are required to run a bot successfully in the Automation 360 Control Room.

Edit bot-dependent text-based files

As a Bot Creator, you can open, view, edit, and save bot-dependent text-based files directly inside the workbench. Automation 360 supports more than 40 text-based file formats, such as TXT, XML, JSON, and Javascript.

- You must have a Bot Creator license.
- You must be assigned a custom role, with the **View content** and **Check out** permissions assigned at the folder level.

If you have the **Check in** permission, you can check in the edited files to the public workspace.

1. Log in to the Control Room as Bot Creator.
2. In the **Private** page, expand the **Bots** folder and select the folder that contains the bot-dependent text-based files that are added as dependencies.

Note: You can edit only the text-based dependent files.

3. Select the file that you want to edit.
4. From the actions menu (vertical ellipses) on the right, click **Edit file** to open the file in the text editor.
The file opens up with all the formatting effects.

For example, XML files open up with the same formatting as that in code editor, providing you with a similar experience.

5. Make changes to the file and click **Save**.
The changes made to the file are saved.

6. Click **Close**.

Check out non-bot file dependencies

Check out the specific versions of the non-bot file dependencies from the public workspace to the private workspace to create an editable copy of the file.

Ensure you have completed all the prerequisites for checking out non-bot file dependencies: [Prerequisites for checking out bot and dependencies](#).

1. Log in to the Control Room as a Bot Creator or a Citizen Developer user.
2. On the left pane, click **Automation**.
A list of available bots, forms, and non-bot files are displayed.
3. You can choose to check out either one file or multiple files simultaneously.
 - Select the file dependency that you want to check out, click the actions menu (vertical ellipsis), and click **Check out file**.
 - Select the file dependencies that you want to check out and click **Check out checked items**.

Option	Steps
Check out file	Select this option to check out the latest version of the dependent file.
Advanced options	<p>Select this option to select a specific version of the dependent file to check out.</p> <ol style="list-style-type: none"> a) Click Advanced options. b) Select the version of the dependent file to check out. c) Add or remove further dependencies if any. d) Select the version of these dependencies. e) Review the dependencies (Overwritten, Missing, Cloned, Skipped.) f) Click Check out.

The file appears in the same folder structure in the private workspace.

4. To cancel the checked-out dependent file, click the **Cancel check out for file** option.

You can use this option from either the public or the private workspace.

In the public workspace, the file status changes to **Public**, and the file is available for check out by another user with the appropriate permissions. In the private workspace, the file status changes to **New** if any changes were made to the file. If there are no changes, the file is replaced with a clone.

View version history of non-bot file dependencies

You can now view the version history of your non-bot file dependencies such as TXT, XML, JSON, XLS, VBS, CSV, Javascript files, to identify relevant changes performed by other users to your files on a specific date and time along with the check-in messages.

You must have check-in and check-out permissions.

You can view the version history of the non-bot file dependencies available in the public workspace (only if there are checked-out files). However, there is no version history available for new and cloned files.

1. Log in to the Control Room.
2. On the left pane, click **Automation**.
A list of bots, forms, and dependencies are displayed.
3. Select the dependency file for which you want to view the version history. Hover over the actions menu (vertical ellipsis) on the right and click **View history file**.
A message appears listing all the versions of the selected file in a sequence (latest revision on the top and first revision at the bottom). The information includes the version number, check-in message, date and time of check-in, and the username that made the check-in.

Actions to build bots

Use actions to build an automation workflow and to instruct a bot what to do. The available actions are located in the Actions palette of the Bot editor in the Control Room.

Actions, packages, and dependencies

Actions are grouped into packages based on the technology they automate. For example, the Excel advanced package contains Excel-related actions, such as **Open workbook**, **Go to cell**, and **Delete cell**, which you can insert in the Bot editor to automate a spreadsheet process.

Each package is updated and enabled individually to support new functionality. New bots are built with the default version. Existing bots are not automatically updated. They run using the same package version that they were built with until the Bot Creator manually updates to the new version.

When the Control Room deploys a bot, the packages used to create the automation are collected and sent to the Bot Agent on the destination device. The Bot Agent caches the packages so that it does not require updates each time the bot runs.

To shorten the runtime the first time a bot runs on a device, preload the packages using the **Preload packages** option in the Bot editor. The system loads the packages to `\ProgramData\AutomationAnywhere\GlobalCache` on the local machine for quick access at runtime.

After an action from a package is used in a bot, that package becomes a dependent file of that bot.

- Learn more about managing packages in [Packages](#) on page 1832.
- Developers can learn more about creating packages in [Package SDK](#) on page 3343.
- Learn more about managing bots and package dependencies in [Bot dependencies](#) on page 2268.

Packages and exe files

Packages	exe process files
DLL	Automation.CSharpDLLWrapper.exe
Database	Automation.DatabasePlayer.exe

Working with actions

Important: Each action in a package provides minimum compatible Control Room and Bot Agent version information when you create bots. So you can update your bots and reduce runtime errors caused by an incompatible Control Room or Bot Agent version.

You can configure actions in the Bot editor. Double-click the action to view the fields and features that you can configure, and double-click or drag an action to insert it into the automation.

Move the mouse over the vertical ellipsis at the top right of an action icon to access the following features:

Copy action	Duplicate the action.
Cut action	Copy the action and remove it from the bot code.
Paste after action	Paste the copied action below the selected action.
<hr/> <p>Note: This option only appears when there is an action in the clipboard.</p> <hr/>	
Delete action	Remove the action from the bot code.
Disable action	At run time, bot ignores the action until you enable it.
Enable breakpoint	Pauses the bot for debugging purposes. Debugging your automations on page 2263
Step over	Use the Step over icon to go to the next action in debug mode. By default, it starts from the first action in debug mode.

You can edit multiple actions at a time, using the toolbar at the top of the Bot editor.

Find in this bot (Search box)	Search for any text or action such as a package name, actions name, string name, or variable name in the Flow, List, or Dual view of the Task Bot. You can search text across multiple pages of the bot and do not require the pages to be loaded manually. This feature is useful for viewing or editing a bot with longer code lines to determine where the searched text, such
-------------------------------	---

as variables, strings, or actions is used and in which line.

- You can search only within the lines of the code in the Bot editor.
- The search is not case-sensitive.

Run from here

Use the Run from here option to execute the bot from a specific line in the Bot editor by skipping all the lines of code before it. This feature helps to execute a particular code block quickly and easily without running the complete bot.

Note: When you use an action within the conditional packages such as If, Loop, or Error handler in the bot, the **Run from here** option is not available from that action. However, you can use the **Run from here** option from If, Loop, or Error handler actions.

Copy items

Copy actions to a clipboard so they can be duplicated within the bot.

Cut items

Copy the actions and remove them from the bot code.

Paste items

Paste one or more actions after the highlighted action. If you have not highlighted an action, the actions are appended to the end of the automation sequence.

Note: This icon is only enabled when there are actions in the clipboard.

Copy to shared clipboard

Copy actions, triggers, and metadata to a clipboard that is shared between bots.

Paste from shared clipboard

Paste actions, triggers, and metadata from another bot.

Note: This icon is only enabled when there are actions in the shared clipboard.

Note: The **Copy to shared clipboard** and **Paste from shared clipboard** options are enabled only for users with Bot Creator privileges.

The **Copy to shared clipboard** option is not displayed if the bot is in Debug mode and you have selected only one line of code. However, this option appears when you select multiple lines of a code.

Auto-save functionality of events in Bot editor

In the Bot editor, when you use actions to build an automation, when a bot is not manually saved, an auto-save is performed and the bot now automatically saves the changes for specific events.

Note: The auto-save functionality is currently available only for specific events.

Some of the events that support auto-save functionality are as follows:

- Recorder: When you create a bot with certain actions and click **Recorder**, the event is saved, and when the recording is complete, the event is automatically saved.
- Variable manager: When you create or edit a variable to insert it in an action, the changes are saved.

Note: The auto-save functionality is not supported when you delete a variable or insert it by pressing F2 to open the variable list.

- Actions menu (vertical ellipsis): When you select any action from this menu, for example **Packages**, the event is saved automatically. When you make any change to the **Packages** page and return to the Bot editor, the event is saved.
- Find a file: When you click the **Find a file** icon, the bot is saved if it is not manually saved. Also, after you click the **Add** option, the bot is automatically saved.
- Dialog boxes: When a dialog box is opened, it is automatically saved if any changes are made.

Note: Auto-save is triggered only for top-level dialog boxes and not for nested dialog boxes.

- Deleting variables: When you delete unused variables, the event is saved.
- Bot name change: If you edit the name of a bot, the event is saved.

[Bot editor for creating bots](#) on page 2152

The Bot editor enables users to create and edit bots on any device and from anywhere the user can access a web browser.

Advanced search option in Bot editor

When you edit or view a bot, you can use the advanced search feature to find the exact line of action and the corresponding details where the search text appears, select the search filter criteria, and navigate through the search results.

Search for any text value or variable name within action details across a bot by using the **Advanced search** feature. You can access **Advanced search** from the Bot editor in one of the following ways:

- Click the **Assistant** icon at the top.
- Click **Search in this bot** > **Open advanced search** icon.
- Use **Ctrl + Shift + F** shortcut keys.

If you enter a search term in the **Search in this bot** field and then click the **Open advanced search** icon, the search term is carried over and displayed on the **Advanced search** page.

The **Advanced search** feature comprises of three components:

Search

In the **Advanced search** page, you can enter a search text in the search box. You can search for a text value, variable name, or long text that has multiple matches.

Figure 2: Search

You can also select the search filter criteria and navigate through the search results.

Note: **Advanced search** is not case sensitive.

Search filters

You can use filters to narrow down the search results and quickly locate the search text. The filters can include the following search criteria:

- Canvas (Flow and List views): to search for any text within the canvas that is displayed in the flow and list views.
- Text value: to search for any text value within the action details.
- Variable name: to search for any variable name within the action details.

You can select or clear one or all the filter check boxes depending on the search criteria.

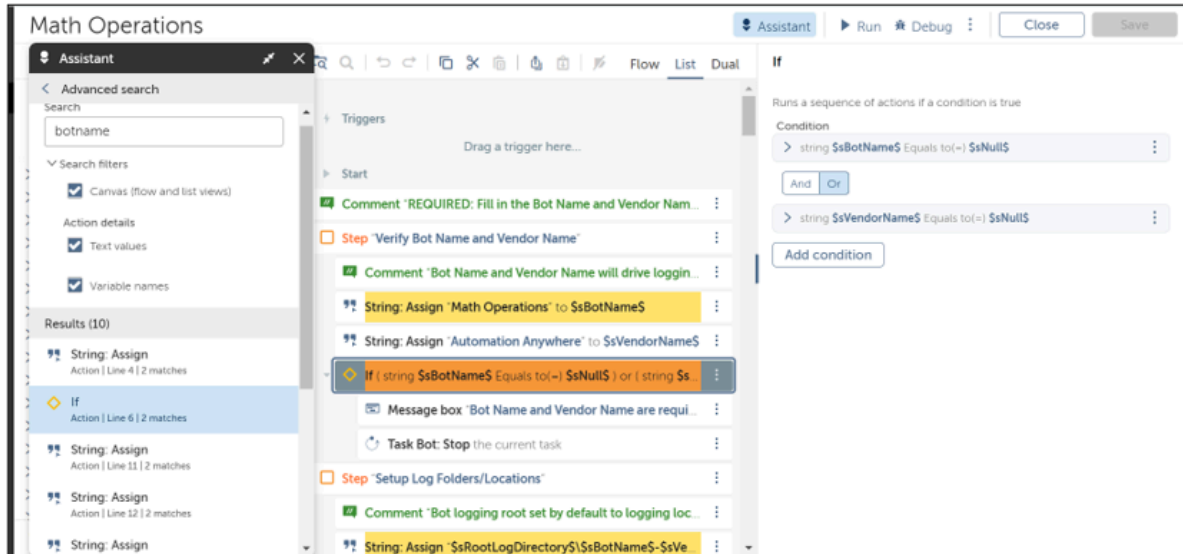

Figure 3: Search filter

When you click a matching item from the action details, for example, if you select the second search result **If | Line 6 | 2 matches** in the **Results** tab, you will see the complete line of action that contains the search text highlighted in the canvas, and the details of the selected action are displayed on the properties panel. You can see that the searched text `botname` is appearing in the if condition, as shown in the properties panel.

Results

When you enter the search text and select the filter criteria, the **Advanced search** page displays the search results based on action names across the different lines of the bot.

The **Results** header displays the total count of matched action names and the count of selected action or line item in a bot. For each action name listed, the line number containing the action and the total matching results found within the action details are displayed as **Action or Trigger | Line number | Number of matches**.

Note: The count displayed in the **Results** header displays only the count of matching line items (or actions) within the bot. However, each line item can have multiple matches and is not counted in the total matching line items. For individual line items, the count of multiple matches is displayed within the particular line item in the **Results** tab.

When you select a specific line item against the action name, the action detail page opens within **Results** tab displaying a list of all matching results within that action.

When there is more than one search result, you can use the **Back** button to go to the previous line and the **Next** button to go to the next item. When you select the **Back** or **Next** button, the action is highlighted in the canvas, and the detail of the corresponding item is displayed in the properties panel.

The following example shows how **Advanced search** works. You are editing a bot with lengthy lines of code. Now you want to search with the text `botname` in the **Assistant** window. The **Results** header shows the total count of 10 matched action names and line numbers with the count of matching line items, such as **If | Line 6 | 2 matches**.

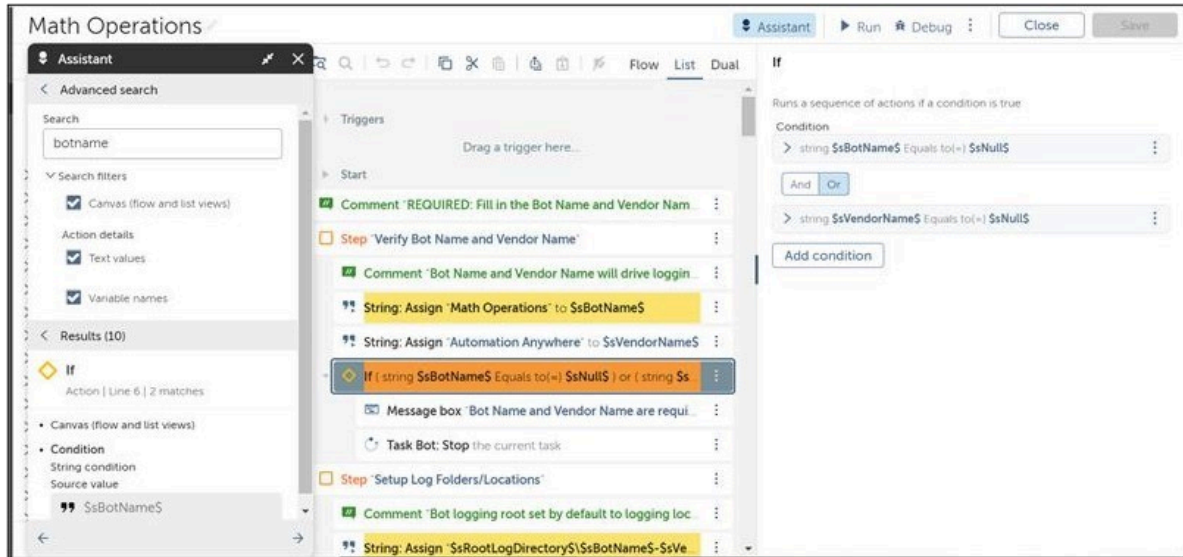

Figure 4: Results

Search and replace option in Bot editor

The search and replace feature enables you to search for any text or string and variable within an action in the Bot editor, and replace it with text or string and variables of the same type. This feature helps in bulk replacement within the bot.

Use one of the following methods to access **Search and replace**:

- Click **Assistant > Search and replace** option.
- Click the **Search in this bot** icon and click the **Open search and replace** icon.
- Use **Ctrl + H** shortcut key.

The **Search and replace** feature comprises of four components:

Search type

Click the **Search type** drop-down menu to select one of the following:

- **String**: To search for text or string.
- **Variable name**: To search for a variable.

Figure 5: Search type

Search

In the **Search** field, enter the term or keyword you want to search. You can search for a text value, variable name, or long text that has multiple matches.

Replace

In the **Replace** field, enter the term or keyword that you want to replace.

- If the **Search type** field is **String**, then enter the text or string in the **Replace** field to replace it.
- If the **Search type** field is **Variable name**, then select the variable from the **Replace** field.

Note: If the search type is a variable, then the **Search** and **Replace** drop-down menus will only display the variable names that are used in the bot.

Points to remember:

- Ensure that you enter different values or select different variables in **Search** and **Replace** fields.
- **Search** field is case-sensitive.
- When you set the **Search type** to **Variable**, the **Search** is applicable only for the used variables.
- Any search text that you have used in the **Search** field of the **Advanced search** window is retained in the **Search** field of the **Search and replace** tab.

For example, if you have used the keyword 'commands' in the **Search** field and then open the **Advanced search** window, the keyword 'commands' is retained in the **Search** field of the **Advanced search** window.

- You can only use the **Search type** > **String** to search a string value. Although you can search and replace the variable types such as number, boolean or datetime, you cannot search or replace their values.

Results

The **Results** header displays the total count of matched action names and the count of selected actions or line item in a bot. For each action name listed, the line number containing the action and the total matching results found within the action details are displayed as **Action or Trigger | Line number | Number of matches**.

You can select one, or all line items where the search keyword appears for replacement. When you click the **Replace** button, all the selected line items are replaced. automatically

Consider the following example when you select the **Search type** as **String**. Enter Please enter your commands to loop in the **Search** field and Please do not edit this in the **Replace** field. Select the **Comment** check box for items you want to replace, and click **Replace** button at the bottom.

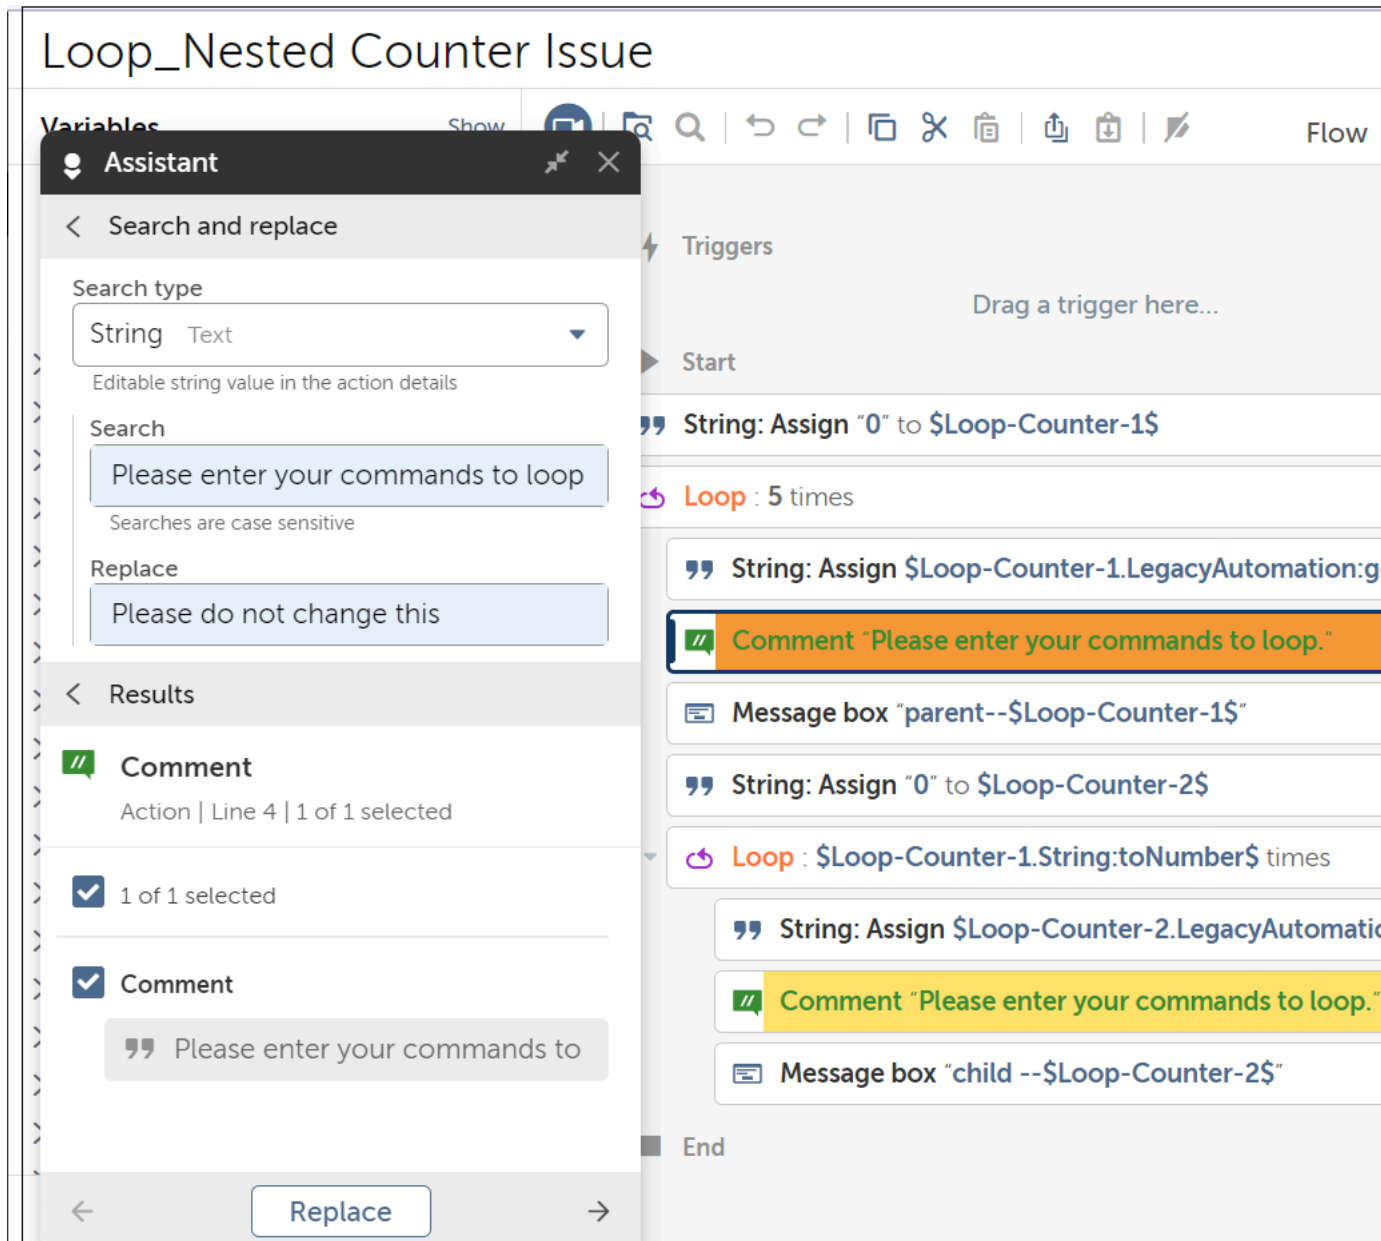

Figure 6: Results for Search type: String

Similarly, here is a sample scenario where you want to search and replace a loop counter variable. You select the **Search type** as **Variable-name**. Use the **Search** drop-down menu to select **Loop-Counter-2**, click **Replace** drop-down menu and select **Loop-Counter**. In the **Results** tab, select the line item where you want to replace the loop counter and click the **Replace** button at the bottom.

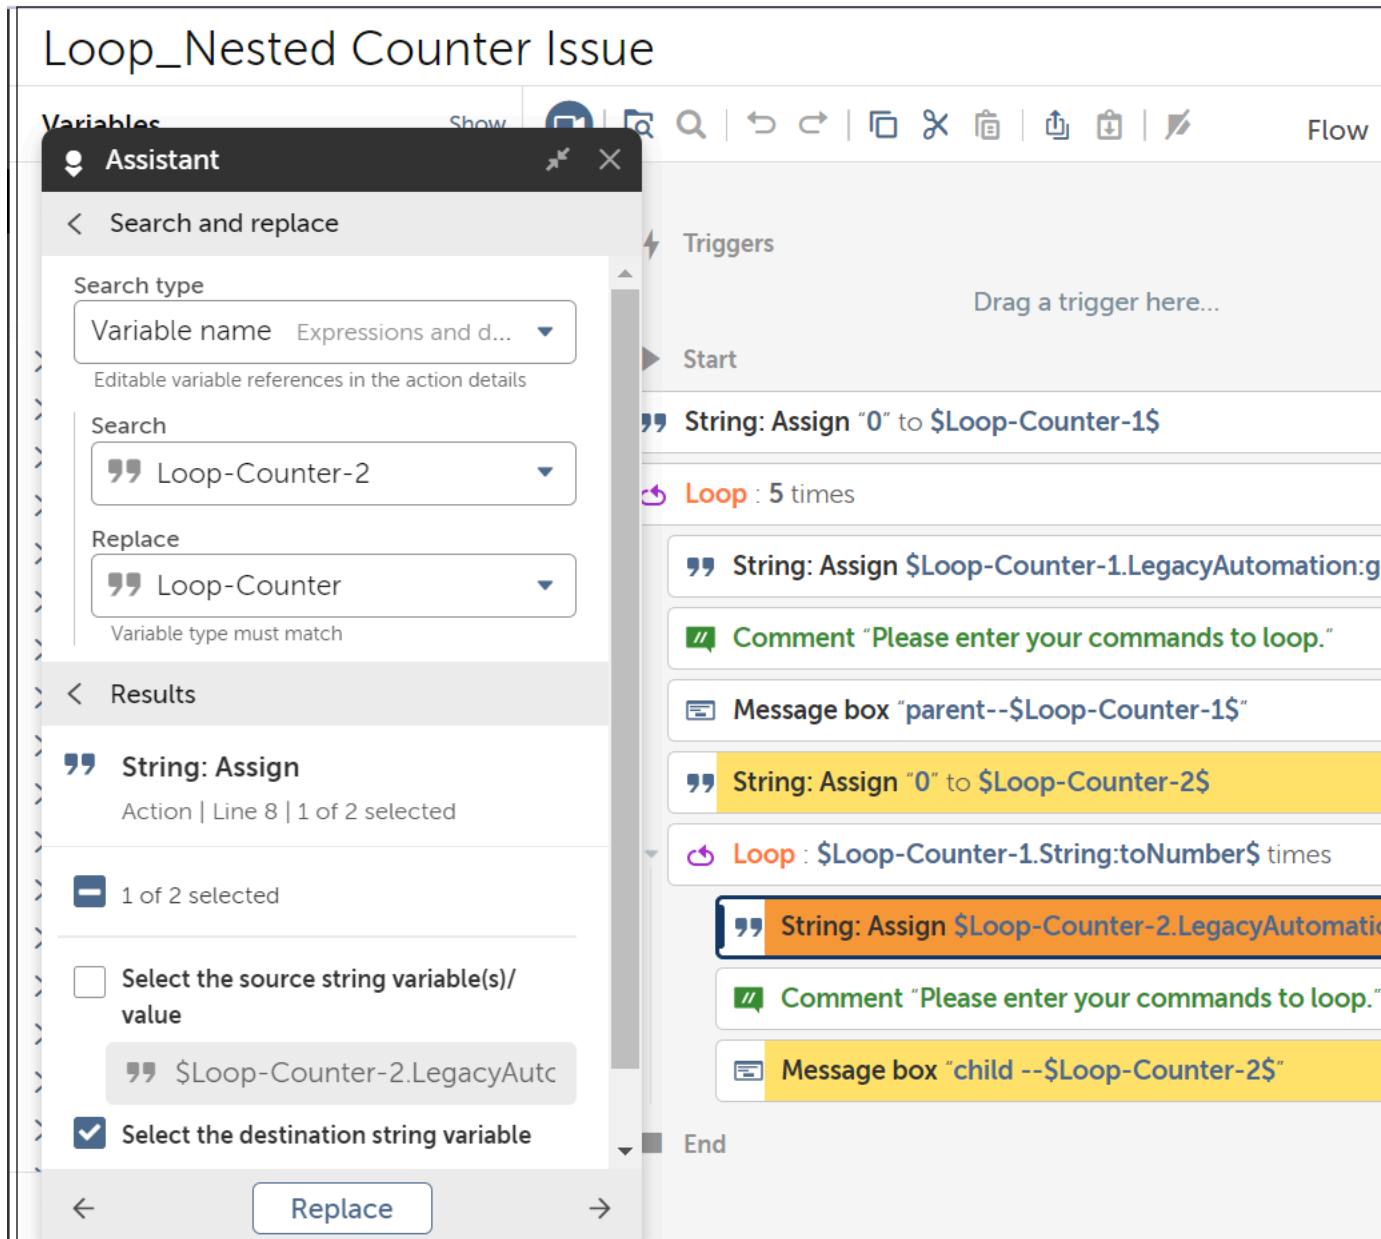

Figure 7: Results for Search type: Variable-name

Points to remember:

- The **Results** tab displays the total count of search terms present in a bot, along with the corresponding line number in the action. However, only the count of matching line items (or actions) within the bot are displayed.

Each line item can have multiple matches and is not counted in the total matching line items. For individual line items, the count of multiple matches is displayed within the particular line item in the **Results** tab.

- The **Replace** button is enabled when you select one of the line items in the **Results** tab.

- Click the line item to get more details from the action. If there are multiple matches for the same line item in the detailed view, they are all displayed and you can select the specific match to replace them.
- The **Next** and **Previous** arrows at the bottom of the dialog allows you to navigate to the next and previous items in the search list.

Active Directory package

Use the `Active Directory` package to automate actions in the Active Directory. An Active Directory is a directory service provided by Microsoft to assist the admin in managing users across a group or organization.

Automation Workspace uses Lightweight Directory Access Protocol (LDAP) to read from and edit users in the Active Directory. The server and domain names are combined to create an LDAP path, which is used to connect to the Active Directory.

Before you start

Before you can use the available actions, in the `Active Directory` package you must perform the following steps:

1. Establish a connection with the Active Directory using the **Connect** action. Use this same session name for the other actions. For more details, see [Using Connect action for Active Directory](#) on page 2289.
2. Use the actions to automate a task.
3. After you have automated all the Active Directory -related tasks, use the **Disconnect** action to terminate the connection to the server .

Operations in the Active Directory package

The `Active Directory` package includes the following operations:

Operation	Description
Computer operations	See Computer operations on page 2285.
Group operations	See Group operations on page 2287.
LDAP operations	See LDAP operations on page 2289.
Organizational unit operations	See Organizational unit operations on page 2291.
User account operations	See User account operations on page 2293.

Active Directory attributes list

The following table provides examples of the most commonly used Active Directory attributes. For a complete list of attributes, the Active Directory administrator can review the attributes listed in the Active Directory server.

Attribute Name	Example
cn (CommonName)	George.Woods
description	Marketing Manager
distinguishedName	DN attribute is a sequence of distinguished names that contains identifying information for an associated user, group, or object. For example, CN=George.Woods,OU=aae,CN=USERS,DC=domain
displayName	George Woods
givenName	George
objectClass	An object class is a defined grouping of attributes such as users, groups, computers, printers, and domain controllers.
objectCategory	Objects attributes are a set of fields that define the mandatory and optional attributes that an object can have. For example, a user object in Active Directory will have attributes such as first Name, last Name, email address, department, and title.
ou (Organizational Unit)	Marketing
sAMAccountName	SJones@domain.com
userAccountControl	You can use the userAccountControl attribute to configure several account settings in Active Directory. The attribute values apply to flags that control password, lockout, disable or enable, script, and other behavior for the user account. For example, for the flag <code>Disabled Account</code> , the value in decimal is 514.
userPrincipalName	SJones

Review the updates in released versions of the Active Directory package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Computer operations

The computer operations in the Active Directory package contain various actions to automate tasks related to computers, including create, delete, get property, rename, and set property.

Actions in the Active Directory package

The Active Directory package includes the following actions for computer operations:

Action	Description
Create computer	See Create computer action in Active Directory on page 2285
Delete computer	See Delete computer action in Active Directory on page 2285
Get computer property	See Get computer property action in Active Directory on page 2286
Move computer	See Using the Move computer action on page 2286
Rename computer	See Rename computer action in Active Directory on page 2287
Set computer property	See Set computer property action in Active Directory on page 2287

Create computer action in Active Directory

The **Create computer** action in the Active Directory package enables you to create a new object for the computer.

Settings

- Enter the same session name as the one you used in the **Connect** action.
- Enter a name for the computer.
- Optional: Enter a description of the computer.

Delete computer action in Active Directory

The **Delete computer** action in the Active Directory package enables you to delete an existing computer.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter a name for the computer.

Get computer property action in Active Directory

The **Get computer** action in the Active Directory package enables you to retrieve a specific property value for a computer.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter the computer name.
- Enter the property.
- Assign the value to a string variable.

Using the Move computer action

Use the Move computer action to move the computer from an existing location to a new location.

Ensure there is an existing computer.

[Computer operations](#) on page 2285

1. In the **Actions** palette, double-click or drag the **Move computer** action from the **Active Directory** package.
2. Add the computer name:
 - Select the name from the server:
 - a) Click **Add computer from server**.
 - b) Enter the host and domain credentials in the **Connect to server** window and click **Connect**.
 - c) In the **Select computer** window, select the computer name from the **Domain Objects** panel and click **Apply**.
 - Enter the name in the **Computer name** field.
3. Add the LDAP path: or perform the following steps if you choose the option :
 - Enter the path in the **Move to** field.
 - Click **Select computer object** and perform these steps:
 - a) Enter the host and domain credentials in the **Connect to server** window and click **Connect**.
 - b) In the **Select computer** window, select the destination server path from the **Domain Objects** panel and click **Apply**.
4. Enter the same session name in the **Active Directory session** that you used in the **Connect** action.
5. Click **Save** and **Apply**.

Rename computer action in Active Directory

The **Rename computer** action in the Active Directory package enables you to rename an existing computer.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter a name for the computer.
- Enter a new name for the computer.

Set computer property action in Active Directory

The **Set computer property** action in the Active Directory package enables you to assign a value to a computer property.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter the computer name.
- Enter the property to update.
- Enter the new value.

Group operations

The group operations in the Active Directory package contain various actions to automate tasks related to groups, including create, delete, get property, and set property.

Actions in the Active Directory package

The Active Directory package includes the following actions for group operations:

Action	Description
Create group	See Create group action in Active Directory on page 2287
Delete group	See Delete group action in Active Directory on page 2288
Get group property	See Get group property action in Active Directory on page 2288
Rename group	See Rename group action in Active Directory on page 2288
Set group property	See Set group property action in Active Directory on page 2289

Create group action in Active Directory

The **Create group** action in the Active Directory package enables you to create a new group.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter a unique name for the group.
- Optional: Enter a description for the group.
- Select the group scope from the following options:
 - **Domain Local**
 - **Global**
 - **Universal**

Group scope

- Select the group type from the following options:
 - **Security**: Provides users with access rights to folders.
 - **Distribution**: Sends emails to a group of users.

Delete group action in Active Directory

The **Delete group** action in the Active Directory package enables you to delete an existing group.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter the name of the group to delete.

Get group property action in Active Directory

The **Get group property** action in the Active Directory package enables you to retrieve a specific property value for the group.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter the group name.
- Enter the property.
- Assign the value to a string variable.

Rename group action in Active Directory

The **Rename group** action in the Active Directory package enables you to rename an existing group.

Settings

- Enter the same session name as the one you used in the **Connect** .

- Enter the group name.
- Enter a new name for the group.

Set group property action in Active Directory

The **Set group property** action in the Active Directory package enables you to assign a value to a group property.

Settings

Assigns a value to a group property.

- Enter the same session name as the one you used in the **Connect** .
- Enter the group name.
- Enter the property to update.
- Enter the new value.

LDAP operations

The Lightweight Directory Access Protocol (LDAP) operations in the Active Directory package contain various actions to automate tasks related to LDAP, including connect, disconnect, and run query.

Actions in the Active Directory package

The Active Directory package includes the following actions for LDAP operations:

Action	Description
Connect	See Using Connect action for Active Directory on page 2289
Disconnect	Closes the connection with the LDAP server.
Run query	See Run query action in Active Directory on page 2290

Using Connect action for Active Directory

Use the **Connect** action to establish a connection with an Active Directory server. This is the first action you must use to automate an Active Directory related task.

This action enables you to provide the server credentials and details, and associate this information with a session name. Use this same session name for the other Active Directory actions so that you have to provide the server information only once.

To establish a connection with an Active Directory server, follow these steps:

1. In the Actions palette, double-click or drag the **Connect** action from the Active Directory package.
2. Enter a session name.
3. Enter or create the LDAP URL:

- **Parent path:** Enter the LDAP URL that identifies the server that hosts the Active Directory services.

For example, LDAP://192.168.2.60/DC=corporate,DC=com

- **Build parent path:** Create the LDAP URL:
 - a) Click the **Build parent path** option to connect to the Active Directory server.
 - b) In the **Connect to server** window, enter the host and domain credentials, and click **Connect**.
 - c) In the **Object Explorer** window, select the specific path from the **Objects** panel.
 - d) Verify the selected LDAP URL path in the **Preview** field and click **Apply**.

4. In the **Login user** field, provide your username with one of the following options:

- **Credential:** Select a credential from the Credential Vault. [Credentials and credential variables in the Bot editor](#) on page 2254
- **Variable:** Select a variable holding a credential data type value. [Your variables \(user-defined\)](#) on page 2241
- **Insecure string:** Enter a value or select a variable.

Important: Values entered using this option are not encrypted.

5. In the **Login password** field, provide your password with one of the following options:

- **Credential:** Select a credential from the Credential Vault. [Credentials and credential variables in the Bot editor](#) on page 2254
- **Variable:** Select a variable holding a credential data type value. [Your variables \(user-defined\)](#) on page 2241
- **Insecure string:** Enter a value or select a variable.

Important: Values entered using this option are not encrypted.

6. Click **Save**.

7. After you have automated all the Active Directory-related tasks, terminate the connection to the server using the **Disconnect** action.

Run query action in Active Directory

The **Run query** action in the Active Directory package enables you to run a specified Active Directory query. The query results are stored in a list variable, either for object names or LDAP paths, depending on the option selected.

Settings

- Enter the same session name as the one you used in the **Connect**.
- Input the query. For example: (&(objectCategory=person)(objectClass=user)(name=A*))
- Specify the return type. Select either the **Object Name** or **LDAP Path** option.
- Assign the value to a string variable.

Organizational unit operations

The organizational unit operations in the Active Directory package contain various actions to automate tasks related to organizational units, including create, delete, and rename organizational units, and get and set property.

Actions in the Active Directory package

The Active Directory package includes the following actions for organizational unit operations:

Action	Description
Create organizational unit	See Create organizational unit action in Active Directory on page 2291
Delete organizational unit	See Delete organizational unit action in Active Directory on page 2291
Get organizational unit property	See Get organizational unit property action in Active Directory on page 2292
Move organizational unit	See Using the Move organizational unit action on page 2292
Rename organizational unit	See Rename organizational unit action in Active Directory on page 2293
Set organizational unit property	See Set organizational unit property action in Active Directory on page 2293

Create organizational unit action in Active Directory

The **Create organizational unit** action in the Active Directory package enables you to create a new object for the organizational unit.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter a name for the organizational unit.
- Optional: Enter a description of the organizational unit.

Delete organizational unit action in Active Directory

The **Delete organizational unit** action in the Active Directory package enables you to delete an existing organizational unit.

Settings

- Enter the same session name as the one you used in the **Connect** .

- Enter the name of the organizational unit to delete.

Get organizational unit property action in Active Directory

The **Get organizational unit property** action in the Active Directory package enables you to retrieve a specific property value for an organization and assigns the results to a variable.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter the organizational unit name.
- Enter the property.
- Assign the retrieved value to a string variable.

Using the Move organizational unit action

Use the Move organizational unit action to move an organizational unit from an existing location to a new location.

Ensure there is an existing organizational unit.

[Organizational unit operations](#) on page 2291

1. In the **Actions** palette, double-click or drag the **Move organizational unit** action from the Active Directory package.
2. Add the organizational unit name:
 - Add the name from the server by performing these steps:
 - a) Click **Add organizational units from server**.
 - b) Enter the host and domain credentials in the **Connect to server** window and click **Connect**.
 - c) In the **Select organizational unit** window, select the organizational unit name from the **Domain Objects** panel and click **Apply**.
 - Enter the name in the **Organizational unit name** field.
3. Add the LDAP path: or perform the following steps if you choose the option **Select organizational unit object**
 - Enter the path in the **Move to** field.
 - **Select organizational unit object** and perform these steps:
 - a) Enter the host and domain credentials in the **Connect to server** window and click **Connect**.
 - b) In the **Select organizational unit** window, select the destination server path from the **Domain Objects** panel and click **Apply**.
4. Enter the same session name in the **Active Directory session** that you used in the **Connect** action.
5. Click **Save** and **Apply**.

Rename organizational unit action in Active Directory

The **Rename organizational unit** action in the Active Directory package enables you to rename an existing organizational unit.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter the name of the organizational unit to rename.
- Enter the new name.

Set organizational unit property action in Active Directory

The **Set organizational unit property** action in the Active Directory package enables you to assign a value to an organizational property.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter the organizational unit name.
- Enter the property to update.
- Enter the new value.

User account operations

The Active Directory package contains various actions to automate tasks related to user account management, including create, delete, get property, remove, rename, and set property.

Actions in the Active Directory package

The Active Directory package includes the following actions for user account operations:

Note: We now support Active Directory user operations by logon name with domain and can provide the domain name to extract the user details. When you retrieve user property or perform any user operation based on the logon name (userPrincipalName), and if the user domain name differs from the domain specified in the LDAP path, the user properties are now successfully retrieved regardless of whether it contains a domain name or not.

For example, LDAP Path: LDAP://ADServer/DC=automation, DC=net

User	Logon name
userPrincipalName: kim@aaengg.net	User can provide logon name as kim@aaengg.net.
userPrincipalName: shaun@aasales.net	User can provide logon name as shaun@aasales.net.

User	Logon name
userPrincipalName:sarah@automation.net	user can provide a logon name as either sarah or sarah@automation.net.

When you perform any user action on the logon name, and if the logon name has a duplicate user under subDomain and subDomain@rootDomain, the user property is retrieved for the user with the root domain.

For example, LDAP Path: LDAP://ADServer/DC=automation, DC=net

- User 1: userPrincipalName (logon name) is kim@aaengg.net.
- User 2: userPrincipalName (logon name) is kim@aaengg.net@automation.net.

If you enter the logon name as kim@aaengg.net or kim@aaengg.net@automation.net, the operations will be performed on the second user that is kim@aaengg.net@automation.net.

Action	Description
Add users to group	See Using the Add users to group action on page 2294.
Create user	See Using the Create user action on page 2295.
Change user password	See Change user password action in Active Directory on page 2296
Delete user	See Delete user action in Active Directory on page 2296
Disable user account	See Disable user account action in Active Directory on page 2296
Enable user account	See Enable user account action in Active Directory on page 2297
Get all users of a group	See Get all users of a group action in Active Directory on page 2297
Get user property	See Get user property action in Active Directory on page 2297
Remove users from group	See Using the Remove users from group action on page 2297.
Rename user	See Rename user action in Active Directory on page 2298
Set user property	See Set user property action in Active Directory on page 2298
Update account options	See Update account options action in Active Directory on page 2299
Update user details	See Using the Update user details action on page 2299

Using the Add users to group action

Use the **Add user to group** action to add an existing user to a user-created group.

Ensure there is an existing user and group.

[User account operations](#) on page 2293 | [Group operations](#) on page 2287

1. In the **Actions** palette, double-click or drag the **Add users to group** action from the **Active Directory** package.
2. From the **Select user** field, select one of the following options:
 - **Add user manually:** Enter the **Name** and **Ldap path** of the user in the **Add user** window and click **Add**.
 - **Add users from server:** Add an existing user from the server:
 - a) Enter the host and domain credentials in the **Connect to server** window and click **Connect**.
 - b) In the **Select user** window, select the user from the **Objects** panel and click **Add user**.

The user name and LDAP path of the user is added in the **Select user** table.

3. Add the user to the specified group by choosing one of the following options:
 - **Group name:** Enter the group name to add the existing user to a specific group.
 - **Select user group:** Add an existing user to a group:
 - a) Enter the host and domain credentials in the **Connect to server** window and click **Connect**.
 - b) In the **Select user** window, select the group from the **Objects** panel to add user to the destination group and click **Apply**.
4. Enter the same session name in the **Active Directory session** that you used in the **Connect** action.
5. Click **Save** and **Apply**.

For more information on how to use some of the actions (including Add user to group), see this example topic [Example using user account actions from Active Directory package](#) on page 3131

Using the Create user action

Use the **Create user** action to configure and activate a new user.

Connect to the Active Directory server.

[Using Connect action for Active Directory](#) on page 2289

1. In the **Actions** palette, double-click or drag the **Create user** action from the **Active Directory** package.
2. In the **Session name** field, enter the session name that you provided in the **Connect** action.
3. Enter a user name.

For example, John Smith.
4. Enter the logon name.

The user will use this value to log in to the account.
For example, john.smith.
5. Enter the user's first name.
6. Optional: Enter these user details: last name, display name, initials, email address, description, department, and title.

7. Select **Active user** to activate the user.
8. Select the **Password settings** check box to set the password for the user.
9. Enter the password.
You can select **Credential** to use a value from the Credential Vault, **Variable** to use a credential variable, or **Insecure string** to manually enter a password.
10. Select the option that enables the user to either change or not change their password at the next login.
If you choose the **Don't require password change at next login** option, you have additional options to select.
 - **User can't change password**
 - **Password doesn't expire**
11. Click **Save**.

Change user password action in Active Directory

The **Change user password** action in the Active Directory package enables you to change the user password.

Settings

- Enter the user name. You can select **Credential** to use a value available in the Credential Vault, **Variable** to use a credential variable, or **Insecure string** to manually enter a user name.
- Enter the new password. You can select **Credential** to use a value available in the Credential Vault, **Variable** to use a credential variable, or **Insecure string** to manually enter a password.
- Enter the same session name in the **Active Directory session** that you used in the **Connect** action.

Delete user action in Active Directory

The **Delete user** action in the Active Directory package enables you to delete an existing user.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Select whether to search for the user by **User name** or **Logon name**.

Note: Before removing a user, make certain all unfinished development of bots are checked-in.

Disable user account action in Active Directory

The **Disable user account** action in the Active Directory package enables you to disable a user account.

Settings

- Enter the same session name as the one you used in the **Connect** .

- Select whether to search for the user by **User name** or **Logon name**.

Enable user account action in Active Directory

The **Enable user account** action in Active Directory package allows you to enable a user account.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Select whether to search for the user by **User name** or **Logon name**.

Get all users of a group action in Active Directory

The **Get all users of a group** action in Active Directory package enables you to retrieve a list of all the users of a group, and assigns the results to a variable.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Enter the group name.
- Specify the return type. Select either the **Object Name** or **LDAP Path** option.
- Assign the value to a string variable.

Get user property action in Active Directory

The **Get user property** action in the Active Directory package enables you to retrieve a specific property value for a user and assigns the results to a variable.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Select whether to search for the user by **User name** or **Logon name**.
- Enter the property.
- Assign value to a string variable.

Using the Remove users from group action

Use the Remove users from group action to remove a user from a group.

Ensure there is an existing user assigned to a group.

[Using the Add users to group action](#) on page 2294

1. In the **Actions** palette, double-click or drag the **Remove users from group** action from the Active Directory package.
2. From the **Select user** field, select one of the following options:
 - **Add user manually**: Enter the **Name** and **Ldap path** of the user in the **Add user** window and click **Add**.
 - **Add users from server**: Add an existing user from the server:

- a) Enter the host and domain credentials in the **Connect to server** window and click **Connect**.
- b) In the **Select user** window, select the user from the **Objects** panel and click **Add user**.

The user name and LDAP path of the user is added in the **Select user** table.

3. To remove the user from a group, select one of the following options:
 - **Group name**: Enter the group name to remove the existing user from a group.
 - **Select user group**: Remove an existing user from a group.
 - a) Enter the host and domain credentials in the **Connect to server** window and click **Connect**.
 - b) In the **Select user** window, select the group from the **Objects** panel to remove user from the group and click **Apply**.
4. Enter the same session name in the **Active Directory session** as you used in the **Connect** action.
5. Click **Save** and **Apply**

Rename user action in Active Directory

The **Rename user** action in Active Directory package enables you to rename the user logon name or the user account name.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Select whether to search for the user by **User name** or **Logon name**.
- Enter the name to search for.
- In the **New name** field, enter the updated name.
- Select from the following options to specify what to update:
 - **Rename user name**
 - **Rename logon name**
 - **Rename user and logon name**

Set user property action in Active Directory

The **Set user property** action in Active Directory package enables you to assign a value to a user property, view the current details, and update it.

Settings

- Enter the same session name as the one you used in the **Connect** .
- Select whether to search for the user by **User name** or **Logon name**.
- Enter the property to update.

- Enter the new value.

Update account options action in Active Directory

The **Update account options** action in Active Directory package enables you to set account attributes for the user.

Settings

- Specify the user name. You can select **Credential** to use a value from the Credential Vault, **Variable** to use a credential variable, or **Insecure string** to manually enter a user name.
- Select the status of the user as **Active** or **Inactive**.
- Select an option indicating whether the user can change their password at the next login or not.

If you choose the **Don't require password change at next login** option, you have additional options to select.

- **User can't change password**
- **Password doesn't expire**
- Enter the same session name in the **Active Directory session** that you used in the **Connect** action.

Using the Update user details action

Use this action to update the details of a user.

Connect to the Active Directory server.

[Using Connect action for Active Directory](#) on page 2289

1. In the **Actions** palette, double-click or drag the **Update user details** action from the **Active Directory** package.
2. In the **Session name** field, enter the session name that you provided in the **Connect** action.
3. Select whether to search for the user by **User name** or **Logon name**.
4. Enter the user's first name.
5. Optional: Enter the following user details: last name, display name, initials, email address, description, department, and title.
6. Click **Save**.

Advanced Classifier package

The Advanced Classifier package enables you to classify documents into a folder structure. You can upload the documents from the folders to the respective learning instance for content extraction in Document Automation.

Note:

- A valid Skillja (3rd Party provider) license is mandatory for utilizing the Advanced Classifier package and the associated actions to process documents. For more information, see [Configuring bring your own key \(BYOK\) for Advanced Classifier package](#) on page 2309.

- Your CSM, AE or PEM can contact contact@scalehub.com to obtain the license details.
- You can download the Advanced Classifier package from [IQ Bot downloads](#) link.
- You must upload this package to the Control Room. For more information, see [Add packages to the Control Room](#) on page 1842.

Actions in the Advanced Classifier package

The package contains the **Train Advanced Classifier**, **Classify Document**, **Classify Pages**, and **Split Document** actions. You can use these actions to create a model file, and use the file to classify uploaded documents into different folders. These actions work as a precursor to document processing.

Actions	Description
Train Advanced Classifier	Use the Train Advanced Classifier action to create a model file that is used by the Classify Document, Classify Pages, or Split Document actions to sort the documents into required categories for input. For more information, see Using the Train Advanced Classifier action on page 2301.
Classify Document	The Classify Document action groups the input documents based on the first page of each document, using the selected model file that is created with the Train Advanced Classifier action. For more information, see Using the Classify Document action on page 2306.
Classify Pages	The Classify Pages action groups the pages of an input document based on the model file that was created using the Train Advanced Classifier action and filters out the pages that do not fit the model. For more information, see Using the Classify Pages action on page 2307.
Split Document	Use the Split Document action to separate the input document into multiple documents based on the selected classification model. For more information, see Using the Split Document action on page 2308.

Note:

The Advanced Classifier package leverages Tesseract OCR for image-based classification. For an extensive list of languages supported by Tesseract OCR, see [Tesseract OCR Supported Languages](#).

Related reference

[Advanced Classifier package updates](#) on page 814

Review the updates in released versions of the Advanced Classifier package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using the Train Advanced Classifier action

Use the **Train Advanced Classifier** action to create a model file that is used by the **Classify Document**, **Classify Pages**, or **Split Document** actions to sort the documents into required categories for input.

Before building the bot, collect example documents and categorize them into folders. Ensure the set of example documents meets the following requirements:

- Has at least two categories.
- A minimum of 15 files per category is required, with a recommendation of 20 files per category.
- There are no restrictions on the maximum number of categories. However, it is important to note that as the training data set and the corresponding model size increase, the performance of the classification process can decline. Therefore, it is advisable to keep the number of categories within a range of 150 per model file for optimal performance.
- The supported file formats are as follows:
 - .tiff
 - .bitmap
 - .jpeg
 - .png
 - .pdf
 - .txt
- We recommend that you provide images with a resolution of 300 dpi (dots per inch). The minimum acceptable resolution is 200 dpi.

Note:

If these minimum requirements are not met, an error message is displayed during bot run-time.

-
1. In the Actions palette, double-click or drag the **Train Advanced Classifier** action from the Advanced Classifier package.
 2. Enter a name for the model file in the **Model name** field.
 3. Select the **Training folder path** from **Desktop folder** or **Variable**. The input folder path must have subdirectories with the names that correspond to the category of the documents that you want to train the classifier on. For example, if you have sales-related documents, the input folder path must have subfolders such as Invoice and Purchase Order.
 4. Optional: If you select **Desktop** file, click **Browse** to change the default filepath. For example, C:\Users\Dave\BankStatement\TrainingData
 5. Use the **Model output path** field to select the directory for the output model file.
 6. In the **License** field, provide a license credential.
 7. If you select **Credential** option, click **Pick** to get a license from the license locker.
 8. In the **Document Split Training** field:
 - If you select **Disabled**:

- a) In Advanced Settings, choose the **Classification Type** from the drop-down menu based on the type of classifier you want to build:
- Visual Classifier
 - Content Classifier
 - Visual and Content Classifier

- b) Optional: Add the **Text Rules**.

If you select **Enabled**:

- a) You will see the following options:
- Merge Unknown Document - Unchecked, by default.
 - Unknown Page Threshold - 30 percent, by default
 - Split Confidence Threshold (or Separation Split Threshold) - 70 percent, by default.
- b) In Advanced Settings, choose the **Classification Type** from the drop-down menu based on the type of classifier you want to build:
- Visual Classifier
 - Content Classifier
 - Visual and Content Classifier

- c) Optional: Add the **Text Rules**.

Note: There must be only one rule file per category. If the rules file is placed outside the category folders shows the following error message:

```
Invalid rule file location
```

-
9. Click **Save** and **Run**.

After creating the model, build a bot to classify input documents. For more information, see [Using the Classify Document action](#) on page 2306.

Set up rules for classifying documents or pages

This topic describes about the capability to set up rules for classifying documents or pages.

Understanding rules and their usage

A rule is used to determine the category to which a document should be assigned. For the below example, a rule can specify a particular phrase like `Annexure` and when the rule is applied to the document text, if that phrase is found, the category associated with the rule will be assigned a high score, such as 80, indicating a strong match.

```
[
{
  "DocumentTypeID": 0,
  "Location": 0,
  "Distance": 1,
```

```

"Score": 80,
"KBGuid": "00000000-0000-0000-0000-000000000000",
"IsEnabled": true,
"ExpectExactSequence": false,
"TextRulePhrases": [
  {
    "Text": "Annexure",
    "IsNegativePhrase": false,
    "PhraseType": 1
  }
]

```

Rules are useful when additional guidance is needed to enhance the accuracy of a classification model in determining the most relevant document category. While technically it is possible to do all classification using a rules, it is not the best practice as the management of rules configuration becomes a significant overhead overtime especially when dealing with large number of categories.

Example of a rule file

A rule file is a json schema and in json format as specified below. The <filename>.json can have multiple rules setup. For a document to be considered during the training process for classification, it must be placed in a designated training folder category, for example, C:\Invoice\Vendor1.

```

[
  {
    "DocumentTypeID": 0,
    "Location": 1,
    "Distance": 3,
    "Score": 90,
    "KBGuid": "00000000-0000-0000-0000-000000000000",
    "IsEnabled": true,
    "ExpectExactSequence": true,
    "TextRulePhrases": [
      {
        "Text": "Annexure",
        "IsNegativePhrase": false,
        "PhraseType": 1
      },
      {
        "Text": "Terms & Conditions",
        "IsNegativePhrase": false,
        "PhraseType": 1
      },
      {
        "Text": "Payment Terms",
        "IsNegativePhrase": false,
        "PhraseType": 1
      }
    ]
  },
  {
    "DocumentTypeID": 2,
    "Location": 2,

```

```

"Distance": 1,
"Score": 95,
"KBGuid": "00000000-0000-0000-0000-000000000000",
"IsEnabled": true,
"ExpectExactSequence": false,
"TextRulePhrases": [
{
"Text": "Addendum",
"IsNegativePhrase": true,
"PhraseType": 5
}
]
}
]
]

```

Configurable properties of a rule file

Configuration	Description
DocumentTypeID	Currently, this field is not supported. For any rule being setup it can be kept static text as 0.
Location	<p>This configuration specifies which location of the document text the rule applicable. The values can be 0, 1, 2, or 3.</p> <ul style="list-style-type: none"> "Location": 0 Any Location: There are no restrictions for finding the phrase, it can be anywhere on the document "Location": 1 First Page: The phrase must be found on the first page of the document. "Location": 2 Inside Caption: The phrase must be found on inside caption text of the document. "Location": 3 Last Page: The phrase must be found on the last page of the document. If only a few pages are provided to the text rule classifier, the last page is the one that will be passed to the classifier..
Distance	<p>This configuration specifies the distance between phrases when the look-up is done on the document text. The rule will only match if the distance is as specified basis this configuration. The values can be 0, 1, 2, or 3.</p> <ul style="list-style-type: none"> "Distance": 0 Same Text Line: All phrases must be in the same text line. "Distance": 1 Next Text Line: All phrases must be in the same text line or have a maximum of one line-break in between each other. "Distance": 2 Same Paragraph: All phrases must be within the same paragraph text. "Distance": 3 Same Page: All phrases must be on the same page.

Configuration	Description
Score	After a rule match is performed, a score is assigned to the category (or training folder) associated with that rule. The score value can range from -100 to 100.
KBGuid	Currently, this field is not supported. For any rule being setup it can be kept static text as 00000000-0000-0000-0000-000000000000
IsEnabled	This allows rule to be enabled or disabled by setting <code>true</code> OR <code>false</code> respectively.
ExpectExactSequence	<p>When looking up multiple phrases in a rule, this configuration specifies exact sequence based matching. For example, if set <code>true</code> in the example, "<code>Text</code>": "<code>Annexure</code>", "<code>Text</code>": "<code>Terms & Conditions</code>", and "<code>Payment Terms</code>" must be present in the document text in this order for the rule to match. It is possible for other text to exist between these phrases, but it is important that the order of these phrases is consecutive, with one following the other.</p> <hr/> <p>Note: Unless its very clear that the expected sequence will follow a specific pattern its recommended to keep this configuration as <code>false</code></p> <hr/>
TextRulePhrases	The <code>TextRulePhrases</code> contains all the phrase text values that needs to be looked up against the document text. It can have one or more phrase text values.
Text	<code>Text</code> - specifies the phrase text value that needs to be looked up against the document text
IsNegativePhrase	<code>IsNegativePhrase</code> - specifies whether the lookup condition is a negative phrase type of lookup. When set <code>true</code> in the example, this will mean that " <code>Text</code> ": " <code>Addendum</code> " is not present in the document text for the rule to match.

Configuration	Description
PhraseType	<p>PhraseType specifies type of match that will be used when phrase text value is looked up against the document text</p> <p>"PhraseType": 1 Fuzzy Matching allows you to use some tolerance in word matching. A phrase is matched if the Levenshtein distance is $\geq 80\%$. For a 5 character word this means 1 character can be different.</p> <p>"PhraseType": 5 Exact Matching requires an exact match of the phrase but still ignores character casing and also includes some filtering of punctuations.</p> <p>"PhraseType": 6 RegularExpression allows you to define a regular expression that is then searched in the original text. No text pre-processing or filtering of punctuation characters is done for this type of matching.</p>

Using the Classify Document action

The **Classify Document** action groups the input documents based on the first page of each document, using the selected model file that is created with the **Train Advanced Classifier** action.

- If not done already, use the **Train Advanced Classifier** action to create a model file.
- Ensure the input files are in required format.

Build a bot with the **Classify Document** action within a **Loop** action to iteratively classify each file in the selected folder.

1. In the Actions palette, double-click or drag the **Classify Document** action from the Advanced Classifier package.
2. In the **Input file** field, provide the default filepath for incoming files for classification:
 - **Control Room file**
 - **Desktop file**
 - **Variable**
3. In the **Classifier** field, provide the filepath of the model file. You can either select the **.zip** folder or extract the **.clsproj3** file from this folder and select it.
 - **Control Room file**
 - **Desktop file**
 - **Variable**
4. Use the **Output folder** path option to save the classification output documents. The pages from the output document are saved in the respective subfolders based on the categories created in the model file.
 - **Desktop folder**
 - **Variable**
5. In the **License** field, provide a license credential.
6. If you select **Credential** option, click **Pick** to get a license from the license locker.

7. Optional: Configure the Confidence threshold (%). If the confidence value of the category prediction of a document is less than the confidence threshold, the document is moved to the `Unclassified` folder.
8. Select or create a list variable to hold the output. The classification results as a list with the following keys:
 - `fileName`
 - `category`
 - `confidence`

Using the Classify Pages action

The **Classify Pages** action groups the pages of an input document based on the model file that was created using the **Train Advanced Classifier** action and filters out the pages that do not fit the model.

- If not done already, use the **Train Advanced Classifier** action to create a model file.
- Ensure the input files are in required format.

Build a bot with the **Classify Pages** action within a **Loop** action to iteratively classify each file in the selected folder.

1. In the Actions palette, double-click or drag the **Classify Pages** action from the Advanced Classifier package.
2. In the **Input file** field, provide the default filepath for incoming files for classification:
 - **Control Room file**
 - **Desktop file**
 - **Variable**
3. In the **Classifier** field, provide the filepath of the model file. You can either select the `.zip` folder or extract the `.c1sproj3` file from this folder and select it.
 - **Control Room file**
 - **Desktop file**
 - **Variable**
4. Use the **Output folder** path option to save the classification output documents. The pages from the output document are saved in the respective subfolders based on the categories created in the model file.
 - **Desktop folder**
 - **Variable**
5. In the **License** field, provide a license credential.
6. If you select **Credential** option, click **Pick** to get a license from the license locker.
7. Optional: Configure the following:

Save classification output variable: Save the classification results as a list of dictionaries with the following keys:

 - `fileName`
 - `index`
 - `category`

- confidence

Note:

- You can select the type of classification in the Advanced Classifier:
 - Image-based classification
 - Text-based classification
 - Both image and text based classification

8. Click **Save** and **Run**.

You can use each subfolder of similar documents to create and train a learning instance to extract data from the documents.

Using the Split Document action

Use the Split Document action to separate the input document into multiple documents based on the selected classification model.

- If not done already, use the **Train Advanced Classifier** action to create a model file.
- Ensure the input files are in required format.

To split a document into multiple documents, do the following:

1. In the **Actions** palette, double-click or drag the **Split Document** action from the **Advanced Classifier** package.

Note: The PDF and TIFF documents with multiple pages are the only valid inputs for the **Split Document** action.

2. In the **Input file** path, select one of the following options to specify the location of the Input file:
 - **Control Room file**
 - **Desktop file**
 - **Variable**
3. Use the **Output folder** path option to save the classification output documents.
 - **Desktop folder**
 - **Variable**
4. In the **License** field, provide a license credential.
5. If you select **Credential** option, click **Pick** to provide a license from the credential vault.
6. Use the **Save split output variable** option to save the classification output documents. Save the classification results as a list of dictionaries with the following keys:
 - fileName
 - documentIndex
 - pageIndex
 - category
 - classConfidence

- splitConfidence

7. Click **Save** and **Run**.

Comparing Advanced Classifier and Document Classifier

This topic is a concise comparison matrix between Advanced Classifier and Document Classifier.

Table 4: Comparison Matrix: Advanced Classifier vs Document Classifier

Capability	Advanced Classifier	Document Classifier
Key for Multiple Matches: Use the key to fetch more than one matching classes	Available	Not Available
Hierarchical Classification: Can process class definition using a complex folder tree structure.	Available	Not Available
Rules for Document Classification: Ability to define rules for document or page classification.	Available	Not Available
Split Document: Feature for handling document splitting during training.	Available	Not Available
Retraining: Incrementally updates the classification model using additional files.	Not Available	Available
OCR Engine: Type of OCR engine used for text extraction and processing.	Tesseract OCR	ABBYY FineReader Engine

Configuring bring your own key (BYOK) for Advanced Classifier package

To leverage BYOK (bring your own key) license for Advanced Classifier package, follow these configuration steps.

Log in as the Admin user type with **Locker** admin.

Create a custom role to access the Credential Vault locker.

1. Navigate to **Administration > Roles > Create role**.
2. Provide a name for the role, such as `advanced-classifier-credential-role`. The `Manage my credentials` and `lockers` permission is automatically selected.
3. Click **Create role**.

Assign the role to the Bot creator and Unattended Bot Runner user types.

4. Navigate to **Administration > Users** and locate the users.
5. For each user, click Edit user and add the `advanced-classifier-credential-role`.
6. Navigate to **Manage > Credentials > Create credential**.
7. Provide a name for the credential, such as `advanced-classifier-credential`.
8. Provide a name for the attribute, such as `ServiceAccount`.
9. Select the **Standard** input option and enter the `License` json key in the **Value** field.
10. Click **Create credential**.
Create a locker to store the key and provide access to other users.
11. Navigate to the **Lockers** tab and click **Create locker**.
12. Provide a name for the locker, such as `advanced-classifier-locker`.
13. Select the `advanced-classifier-credential` and click the right arrow to move the credential to the **Selected column**.
14. In the **Consumers** tab, select the `advanced-classifier-credential-role` and click the right arrow to move the credential to the **Selected** column.
15. Click **Create locker**.

Analyze package

Use the actions in the **Analyze** package to specify the actions and variables to use in the Bot Insight dashboard and widgets. The **Analyze** package enables you to perform transactional analytics for the data that is logged by the variables when the bot runs.

Note: The proxy configuration with authentication is currently not supported.

Actions in the Analyze package

The **Analyze** package includes the following actions:

Action	Description
Close	<p>Closes a transaction.</p> <ul style="list-style-type: none"> • In the Transaction name field, enter the transaction name that you provided in the Open action. • In Dictionary variable, select the following options: <ul style="list-style-type: none"> • All user-defined variables: Include all the user-defined string, numeric, and datetime variables from the bot to populate the Bot Insight dashboards. • Manually select the variables to include in the Bot Insight dashboards.
Open	<p>Opens a transaction. Insert the actions that you want to include for analysis between the Open and Close actions. In the Transaction name field, enter a transaction name.</p>

Using the **Open** and **Close** actions with the **Loop** package

- If you want to capture all the data within the loop in the Bot Insight dashboard, use the **Open** and **Close** actions inside the loop.

Example: If you are using the **For each row in CSV/TXT** iterator in the **Loop** action to read values from each row in a Microsoft Excel sheet, use the **Open** and **Close** actions inside this loop to analyze and capture the data of each row in the Bot Insight dashboard.

- If you want to capture only the last interpreted data of the loop in the Bot Insight dashboard, use the **Open** and **Close** actions outside the loop.

Example: If you are using the **For each row in CSV/TXT** iterator in the **Loop** action to read values from each row in a Microsoft Excel sheet, use the **Open** and **Close** actions outside this loop to capture only the data in the last row of the Excel sheet in the Bot Insight dashboard.

Using the **Open** and **Close** actions with the **Error handler** and **If** packages

- If you want to analyze and capture error messages during bot execution in the Bot Insight dashboard, use the **Open** and **Close** actions with an **Error handler** package.

Example:

1. Create a bot with multiple **If** actions within a loop.
2. To capture errors, within every **If** action, add an **Error Handler > Catch** action.
3. Inside the loop, after every **If** action, add the **Analyze > Close** action to capture the errors inside every **If** condition on the Bot Insight dashboard for analysis.

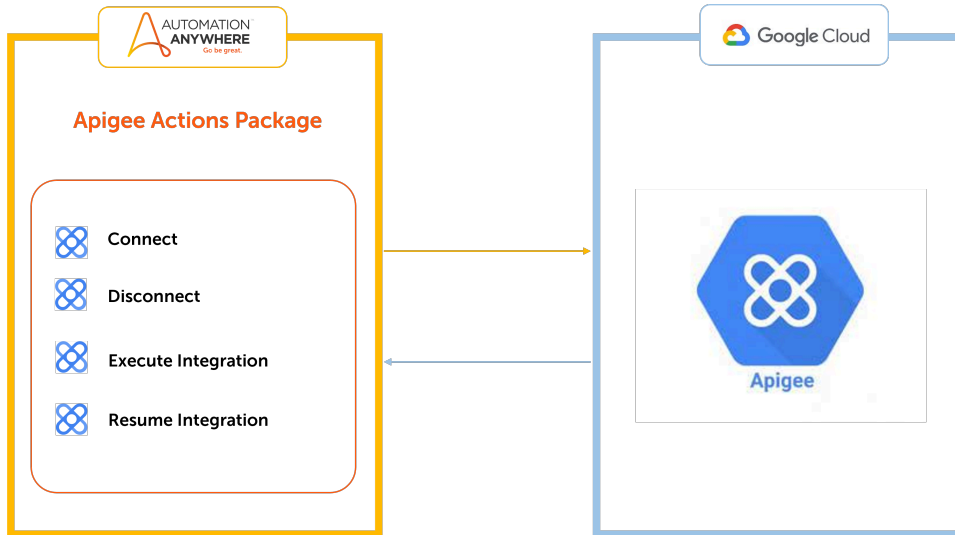

Example task: See the following topic for an example of building a bot to retrieve data from a website to create visualizations in Bot Insight: [Build a Bot Insight dashboard bot](#) on page 3110. The example includes using the **Open** and **Close** actions inside a loop when using the **For each row in CSV/TXT** iterator in the **Loop** action.

Apigee action package

Use the Apigee package to connect to an Apigee instance to run integrations and collaborate efficiently to function as one unit.

Apigee Integration offers business organizations of all sizes the tools needed to connect and manage the multitude of software applications required to support business operations in a digital world. With Apigee Integration's out-of-the-box triggers, configurable tasks, and friendly user interface, you can create enterprise-level integrations with ease. All the Automation 360 actions can be configured to an API trigger to invoke executions for Apigee integrations.

The following illustration shows an overview of the actions that can be used to connect to an Apigee instance and execute integrations:

Related reference

[Apigee package updates](#) on page 815

Review the updates in released versions of the Apigee package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Apigee Connect

You can connect to a Google Cloud Platform (GCP) instance using the **Apigee Connect** action. The GCP manages access to your Apigee instance.

- Create a GCP account ([GCP Cloud](#)) and create a GCloud project.
- Login to your GCloud account at [Google Cloud Project](#) and create a project. If you already have access to a project, you will see your project here.
- Create an OAuth 2.0 Client ID. A client ID is used to identify a single application to Google's OAuth Servers. For more details, see [Apigee Connect](#).

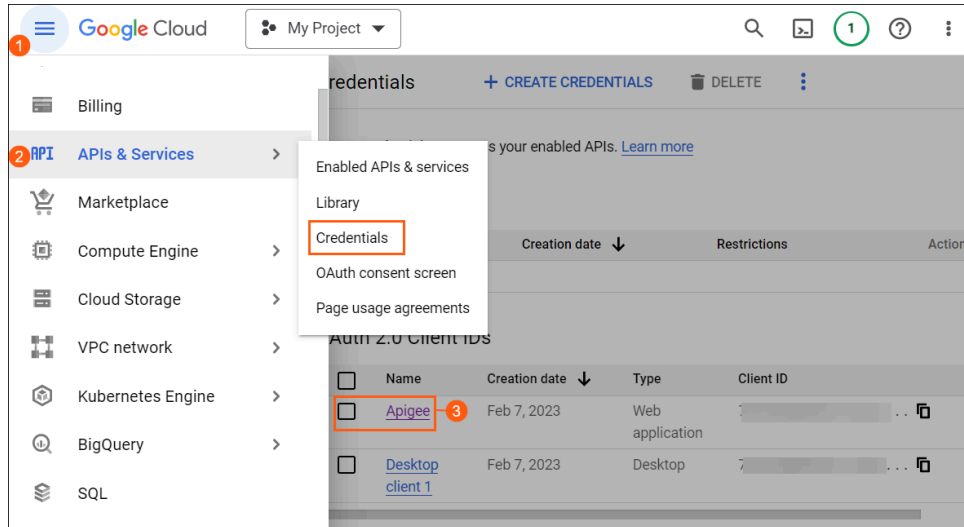

You can connect to an Apigee instance using the **Apigee Connect** action from Automation 360.

You can use different connection methods to connect to Apigee:

- **User Account:** Use this connection method by providing the GCloud account credentials. The GCloud account is required to establish a connection.
- **Service Account:** Use this connection method by providing the GCloud service account key. This method uses the certificate to authenticate between servers rather than user credentials. To create a service account key, see [Creating a service account](#).
- **Control room OAuth connection:** Use this connection method by creating an OAuth connection and storing it in the Control Room.

1. Log in to the Control Room.
2. Create a new bot or edit an existing bot. For more details, see [Create your first bot](#) on page 1429.
3. From the Actions pane, select **Apigee > Connect** and place it under the **Start** of the bot flow.
4. In the **Authentication Type** field, select the authentication method from the drop down list.

5. To view client ID and client secret details in Apigee for **User Account** authentication, complete the following steps:
 - a) Open the [Google Cloud console](#).
 - b) At the top-left, click **Menu > APIs & Services > Credentials**.
 - c) Click on an application under OAuth 2.0 Client IDs that you want to connect.

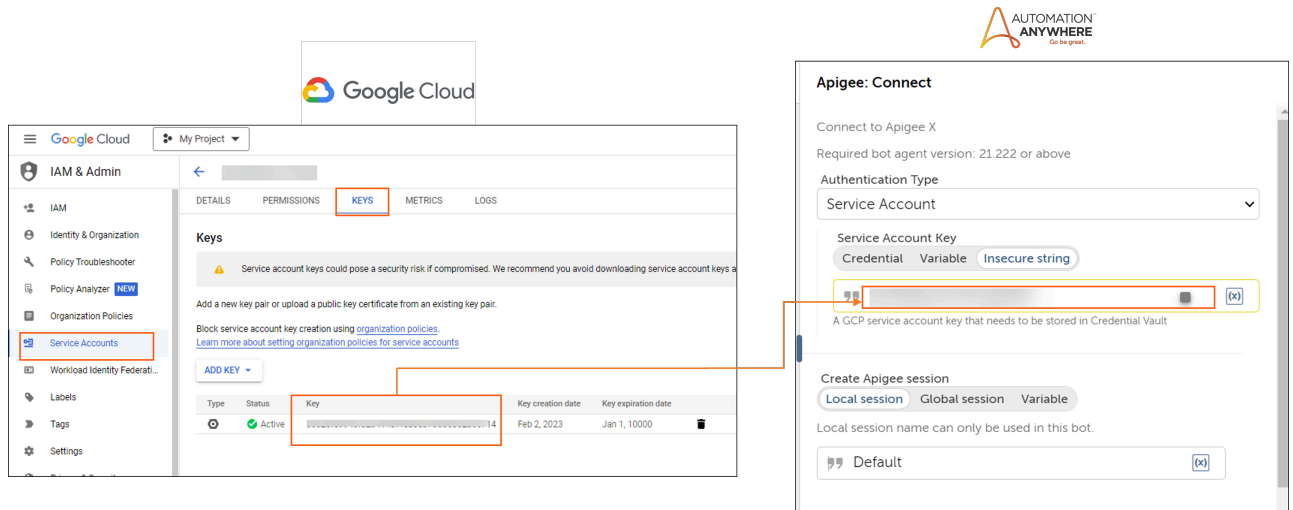

- d) Copy the values from **Client ID**, **Client secret**, and **URI** fields.
6. To connect using User Account, complete the following steps:
 - a) In the **User Email Address** field, enter the email address used to login to the GCloud account.
 - b) In the **Client ID** field, paste the **Client ID** copied from the GCloud. This example uses **Insecure string** whereas you can use **Credential** or **Variable** options for better security.
 - c) In the **Client Secret** field, paste the **Client Secret** copied from the GCloud.
 - d) In the **Redirect URI** field, enter the redirect URI from the GCloud account.
 - e) Enter **Default** as the session name.

Note: You can use one of the following options to specify the **User Email Address/Client ID/Client secret/ Redirect URI**:

- **Credential:** Enables you to use a value in the Credential Vault that contains information about the User Email Address/Client ID/Client secret/Redirect URI.
- **Variable:** Enables you to use a credential variable that contains information about the User Email Address/Client ID/Client secret/Redirect URI..
- **Insecure string:** Enables you to enter the User Email Address/Client ID/Client secret/Redirect URI. User Email Address/Client ID/Client secret/Redirect URI

7. To connect using Service Account, in the **Service Account Key** field, enter the GCloud service account key. This example uses **Insecure string** whereas you can use **Credential** or **Variable** options for better security.

Note: If you do not have access to generate and retrieve the **Service Account Key**, contact your Google Cloud Admin.

8. To configure a **Control room OAuth connection** in Apigee, complete the following steps:
 - a) Complete step 1 to step 5 in [Create OAuth connection](#) on page 1827.
 - b) Open the [Google Cloud console](#).
 - c) At the top-left, click **Menu > APIs & Services > Credentials**.
 - d) Click **CREATE CREDENTIALS > OAuth client ID**.
 - e) Select **Web application**. Enter a name and add the Callback URL from [Create OAuth connection](#) on page 1827 as an authorized redirect URI.
 - f) Click **Create**.
 - g) Copy the client ID and client secret.
 - h) Go to [Create OAuth connection](#) on page 1827 and complete the remaining steps to create an OAuth connection with the above details.
9. To connect using **Control room OAuth connection**, pick an Apigee OAuth connection you have created and stored in the Control Room. For more details, see [Integrate OAuth with Control Room](#) on page 1824.
10. In the **Create Apigee session** field, the session name is displayed as **Default**.

Apigee Disconnect

You can disconnect from your Apigee instance and clear the session using the **Apigee Disconnect** action.

1. From the **Actions** pane, select **Apigee > Disconnect** and place it under the bot flow.
2. Enter the session name and click **Run**.
3. After the bot runs, your Apigee instance is disconnected.

Apigee Execute Integration

You can configure and execute an integration in Apigee using the **Apigee Execute Integration** action.

- Create a GCP account ([GCP Cloud](#)) and create a GCloud project.
- Login to your GCloud account at [Google Cloud Project](#) and create a project. If you already have access to a project, you will see your project here.
- Create an OAuth 2.0 Client ID. A client ID is used to identify a single application to Google's OAuth Servers. For more details, see [Apigee Connect](#).

Use the **Apigee Execute** action to execute an integration in an Apigee instance from Automation 360.

1. Log in to the Control Room.
2. Create a new bot. For more details, See [Create your first bot](#) on page 1429.
3. From the **Actions** pane, select **Apigee > Execute integration** and place it under the **Start** of the bot flow.
4. Click **Discover integrations to configure. Step 1/4: Connect to Apigee X** appears. In the **Authentication Type** drop down, select the authentication method. For more details, see [Apigee Connect](#) on page 2312.
 - **User Account:** Use this connection method by providing the GCloud account credentials.
 - **Service Account:** Use this connection method by providing the GCloud service account key. You need to add the service account key in the following JSON format. It is recommended to store the entire JSON snippet in the credential vault and pick the saved credential during connection.

```
{
  "type": "service_account",
  "project_id": "your_project_id",
  "private_key_id": "your_private_key_id",
  "private_key": "-----BEGIN PRIVATE KEY-----\your_private_key-----
END PRIVATE KEY-----\n",
  "client_email": "your_client_email",
  "client_id": "your_client_id",
  "auth_uri": "https://accounts.google.com/o/oauth2/auth",
  "token_uri": "https://oauth2.googleapis.com/token",
  "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
  "client_x509_cert_url": "your_client_certificate_url"
}
```

- **Control room OAuth connection:** Use this connection method by creating an OAuth connection and storing it in the Control Room.
5. Click **Connect**.
If the credentials are correct, it gets connected to GCloud and the **Step 2/4: Load Integration** screen appears.
 6. Select the following in the **Step 2/4: Load Integration** screen.
 - a) Click the **Project ID** drop-down and select the project ID from where you want to load the integration.
 - b) Click the **Location** drop-down and select the location from where you want to load the integration.

7. Click **Next**.

Step 3/4: Select an Integration screen appears with all the available integrations.

8. Select an integration from the list.

9. Click **Next**.

Step 4/4: Configure my Integration screen appears with all the configuration options.

10. In the **Step 4/4: Configure my Integration** screen, click the **API Trigger** drop-down and select the trigger you want to invoke.

The input parameters are the parameters retrieved from Apigee.

11. Click **Done**.

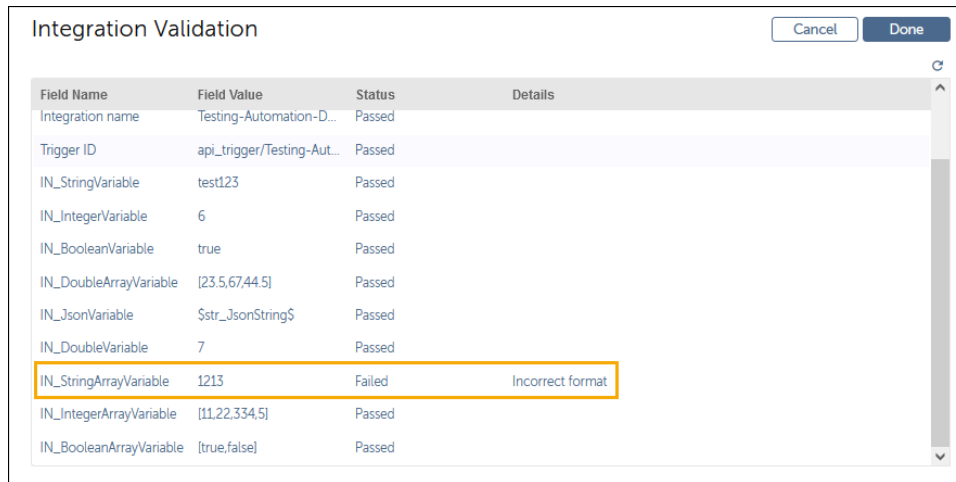

All the selected options are displayed as parameters in the **Apigee: Execute integration** action.

12. Click **Add new input parameter** to manually add the input parameters. You can provide the parameter value for different parameter types as specified in the following table:

Parameter type	Parameter value	Example
String	Specify a string value stored as a variable.	\$str_INString\$
Integer	Specify a number.	9
Double	Specify a decimal number.	20.5
JSON	Specify a JSON string.	\$str_JSONString\$
String Array	Specify string values in an array.	[a,b,c]
Integer Array	Specify integers in an array.	[11,22,334]
Double Array	Specify integers and decimal numbers in an array.	[23.5,27,44.5]

Parameter type	Parameter value	Example
Boolean	Specify boolean value as True or False.	True
Boolean Array	Specify boolean values as an array.	[true,false]
-- (Manual entry)	Specify any value from the above formats.	

13. We recommend that you click **Validate my settings** to validate all the parameters you have provided. If the values are incorrect, you will see the details in the **Integration Validation** window.

14. Enter **Default** as the session name.
15. You can store the execution ID to a variable to verify in Apigee. For example: ExecutionId.
16. To verify the response from the Apigee integration, you can store the response to a variable. For example: Execution.

20 **Execution result (optional)**
 ▾ (x)
Execution result of the integration you want to execute

Note: The output is retrieved as a list of type `list`. To read an individual record (row) in this list, you need to loop through all the dictionary items using the `action` and read or extract the records (rows) individually. For example, the output of `get multiple records` is saved in the variable `list_of_records_any`. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

1. ServiceNow: Authentication Start a "Default" session on SPDI_urls
2. ServiceNow: Get Multiple Records Get a list of "Incident" records using filter type (N
3. Loop : For each item in the list
4. Dictionary: Get value of the key "number" from \$ListItem\$
5. Dictionary: Get value of the key "severity" from \$ListItem\$
6. Dictionary: Get value of the key "short_description" from \$ListItem\$
7. Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
8. ServiceNow: Revoke Authentication End the "Default" session

An orange arrow points from the "Loop" action to a "View variable" dialog box. The dialog box shows the following details:

Type	Subtype
List	Any
Name	Description
list_of_records_array	An ordered group of items
Use as input	
No	
Use as output	
No	
Constant (read-only)	
No	
Default value (optional)	
This list is empty	

time.

Apigee Resume Integration

You can resume an integration that is suspended in Apigee using the **Apigee Resume Integration** action.

You can use the suspend task in Apigee to temporarily pause and then resume the execution of an integration. When an integration is suspended the execution is halted and all tasks after the suspend task are suspended. You can configure an output variable (**Suspension result**) for the suspended task that you can use to resume the integration. You must configure a suspend task element in Apigee to suspend an integration. For more details, see [Suspend an integration](#).

You can use the [Apigee Execute Integration](#) on page 2315 to configure and execute an integration in Apigee. If you use the execute integration to suspend an integration in Apigee, the result shows a suspension ID that you can use to resume the integration.

To revoke the suspension you can use the **Apigee Resume Integration** action. You can use one of the following options to resume an integration:

- **Execution ID:** A unique identifier for the execute integration task that is performed to suspend a task in Apigee.
- **Suspension ID:** A unique identifier for the Suspend task. The value of this variable is set immediately after the integration is suspended.
- **Suspension result:** A variable to store the result of the Suspend task.

1. Log in to the Control Room.
2. Create a new bot or modify an existing bot. For more details, see [Create your first bot](#) on page 1429.
3. From the **Actions** pane, select **Apigee > Resume integration** and place it under the bot flow.
 - a) In the **Project ID** field, enter the GCloud project ID or select a variable if the project ID is stored as a variable.
 - b) In the **Location** field, select the location of the integration you want to resume.
 - c) In the **Integration name** field, specify the name of the Apigee integration.
 - d) In the **Execution ID (optional)** field, you can specify the unique execution ID of the Apigee integration.
 - e) In the **Suspension ID (optional)** field, you can specify the unique ID of the Apigee suspend task.
 - f) In the **Suspension result (optional)** field, you can store the suspension result in one of the following formats:
 - **Text:** You can use a text value for the suspension result.
 - **Dictionary:** You can use a name or value pairs for the suspension result.
 - **Manual entry:** You can manually enter names and values as the suspension result.
 - g) Enter **Default** as the session name.
 - h) In the **Event execution info ID (optional)** field, specify the unique ID of the integration execution.

App Integration package

Extract text from a window and save it to a string variable by using the actions in the App Integration package.

The App Integration package supports the following technologies:

- UNIX shells, such as Cygwin, PowerShell, and GIT shell
- Windows applications, such as Calculator, Command Prompt, and Notepad
- Java applications that are based on the Standard Widget Toolkit and Abstract Window Toolkit, which can draw text using Windows text-drawing APIs

The actions in the App Integration package are based on legacy technology and have certain limitations on specific applications. To seamlessly obtain data from applications and browsers, use the [Recorder package](#) on page 2798.

Building bots with actions from the App Integration package

1. Open the application or file from which you want to capture the text using the **Application > Open program/file** action.

[Application package](#) on page 2326

2. Extract the text using one of the actions from the App Integration package.
3. Use any of the following actions from the String package to manipulate the captured text:
 - **Extract text:** Extracts text from the source string using logical operators.
 - **Split:** Splits the string into multiple strings and stores the output in a list variable.
 - **Trim:** Trims blanks and white spaces from a string.

[String package](#) on page 2957

Actions in the App Integration package

The App Integration package includes the following actions:

Action	Description
Capture area	See Capture area action on page 2323.
Capture scrollable text	See Capture scrollable text action on page 2324.
Capture text of window	See Capture text of window action on page 2325.

Related reference

[Screen resolution dependent packages](#) on page 1739

The screen resolution between the Bot Runner and Bot Creator device should be consistent as when resolution-dependent packages are used to build bots, any screen resolution difference between the Bot Creator and Bot Runner device will impact the bots during runtime.

[App Integration package updates](#) on page 816

Review the updates in released versions of the App Integration package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Capture area action

The **Capture area** action enables you to extract text from within the captured area of a window and saves it to a string variable.

Settings

Extracts text from within the captured area of a window and saves it to a string variable.

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.
 - **Application**: Select from a list of windows, including browser windows, that are currently open on the device.
 - **Browser**: Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- **Variable**: Select an existing window variable to specify the title of the application window title.
- Insert a wildcard character (*) in the **Window title** field to search for window titles that can change.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as ((\w*) -Notepad for all window title names starting with ((\w*) -Notepad, or use **Pattern** value as ((\w) \s) *document-Notepad for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

-
- Optional: Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the bot's ability to identify the target object.

- Click **Capture region** and select the area to capture.
- In the **Save captured text to a variable** field, select a string variable.

Capture scrollable text action

The **Capture scrollable text** action enables you to capture scrollable text from the specified window.

Settings

Captures scrollable text from the specified window.

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.
 - **Application**: Select from a list of windows, including browser windows, that are currently open on the device.
 - **Browser**: Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- **Variable**: Select an existing window variable to specify the title of the application window title.
- Insert a wildcard character (*) in the **Window title** field to search for window titles that can change.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*) -Notepad` for all window title names starting with `((\w*) -Notepad`, or use **Pattern** value as `((\w) \s) *document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

-
- (Optional) Select the **Resize window** option to specify the window dimensions.
This option delivers a more reliable . It resizes the window to the dimensions at which the task was recorded, which enhances the bot's ability to identify the target object.
 - Click **Capture coordinate** to capture the coordinates of the window or a specific control within the window.
 - In the **Save captured text to a variable** field, select a string variable.

Note: The PowerBuilder application is currently not supported.

Capture text of window action

The **Capture text of window** action enables you to extract all the text from a window and saves it to a string variable.

Settings

Extracts all the text from a window and saves it to a string variable.

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.
 - **Application:** Select from a list of windows, including browser windows, that are currently open on the device.
 - **Browser:** Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- **Variable:** Select an existing window variable to specify the title of the application window title.
- (Optional) Select the **Resize window** option to specify the window dimensions.
This option delivers a more reliable . It resizes the window to the dimensions at which the task was recorded, which enhances the bot's ability to identify the target object.
- (Optional) Select the **Use legacy behavior (same as V11)** check box to capture text from a specific window when the Automation Launcher and the target application are running on two different user profiles.
This feature ensures successful bot run by supporting the same application process run by two users. Also, with the introduction of this new option, the App Integration package supports 32-bit applications and replicates the functionality of Enterprise 11 in Automation 360 when capturing text from a window.
- In the **Save captured text to a variable** field, select a string variable.

Application package

Use the **Open Program/File** action in the **Application** package to launch an application or a file. This action supports .exe, .bat, script files, or shortcut paths.

Actions in the Application package

The **Application** package includes the following action:

Action	Description
Open program/file	See Open program/file action on page 2326.

Related reference

[Application package updates](#) on page 818

Review the updates in released versions of the **Application** package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible **Control Room** and **Bot Agent** versions.

Open program/file action

The **Open Program/File** action in the **Application** enables you to launch an application or a file.

Settings

Opens an application or file.

- Enter the name of the application or file, or insert a variable. For example, `chrome.exe`.

Note: You can also enter the full file path in this field.

- Optional: Enter the location of the file that you want to use to open the application in the **Start in path** field.

For example, `C:\Program Files (x86)\Google\Chrome\Application\`

- Optional: In the **Parameters** field, specify the parameters or arguments you want to pass to the program.

For example, if you are using the command line, enter the arguments in this field.

When you enter a file path in the **Location of the program/file** field or **Start in path** field and use a backslash (\) character to separate the file path, when you save the bot, the backslash (\) character is changed to forward slash (/). To support multiple platforms, Automation 360 converts the file paths to a relative path, and the bot uses a forward slash (/) to separate the file paths.

Note: Your bots will continue to run successfully even when the backslash (\) is changed to a forward slash (/) during bot execution.

AWS Comprehend NLP package

The AWS Comprehend NLP package contains actions that enable you to connect to and consume the Amazon Comprehend API to identify the language, sentiment, key phrases, and entities.

Important: This is a beta package and is currently not available with the Automation 360 Enterprise and Cloud editions.

Before you start

You require the following information for an existing AWS account to use these actions:

- **Access key** and **Secret key:** Credentials that authenticate Automation 360 with your AWS account.

See [Access Keys \(Access Key ID and Secret Access Key\)](#).

- **Region:** Specifies the AWS service endpoint.

See [AWS Service Endpoints](#).

Actions in the AWS Comprehend NLP package

Action	Description
Detect language	Identifies the language of the provided content and returns it in ISO 639-1 language code. The output is stored in a string variable. This action supports over 100 languages. For the full list, see Detect the Dominant Language .
Get key phrases	Identifies the main points and returns a list of key phrases. For example, if the input text is about a basketball game, this action returns the names of teams, the name of the venue, and the final score.
Get named entities	Identifies the entities in the provided content such as people, places, organizations, date/time, quantities, branded products, and book titles. The output is stored in a dictionary variable, where each name is a key, and the corresponding entity is the value.
Get sentiment	Analyzes the provided content and returns the overall sentiment and scores for all possible sentiments. An example output of the dictionary values: <code>POSITIVE {Positive: 0.66238534, Negative: 0.0013064129, Neutral: 0.33621928, Mixed: 8.892125E-5}</code> The output is stored in a dictionary variable containing two keys and their corresponding values: <code>sentiment</code> and <code>score</code> .

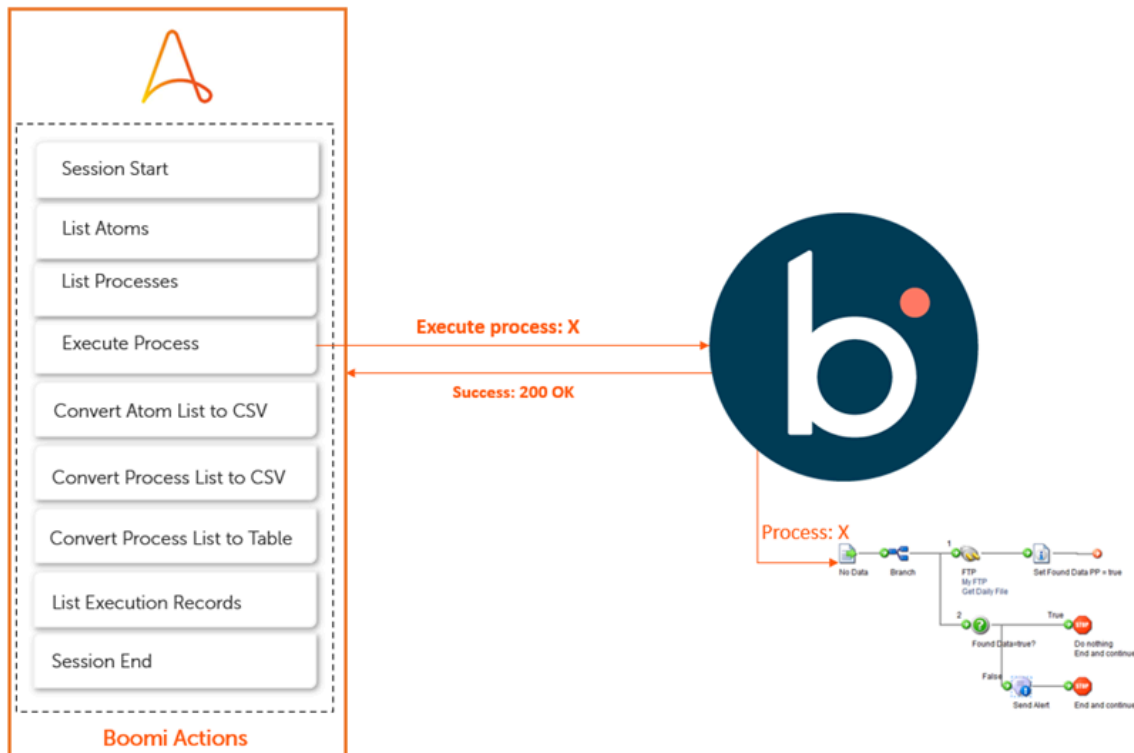

Boomi action package

Boomi Atmosphere is a leading industry on-demand integration service available as a platform-as-a-service (iPaaS) offering. With the Boomi actions package, you can start a session in Boomi from Automation 360 and perform general tasks in Boomi.

Note: The Boomi package is only available via the Bot Store and is not yet generally available in Automation 360. This package is currently undergoing final testing, after which it is anticipated to be generally released as part of Automation 360.

Without extensive training or specialized technical skills, you can build integration flows in Boomi using drag-and-drop. A multitude of connectors to external systems are available out of the box. It simplifies typical integration functions such as transforming between various data formats (EDI, CSV, XML, JSON, and so on) and handling different transport mechanisms (file, FTP, HTTP, and so on). The Boomi action package uses the Boomi APIs to integrate Automation 360 with Boomi.

To perform any action in Boomi using Automation 360, RPA developers need to establish a session with Boomi. After you establish a session is established, you can execute a process from the Automation 360. Additionally, you can list the Atoms and Processes.

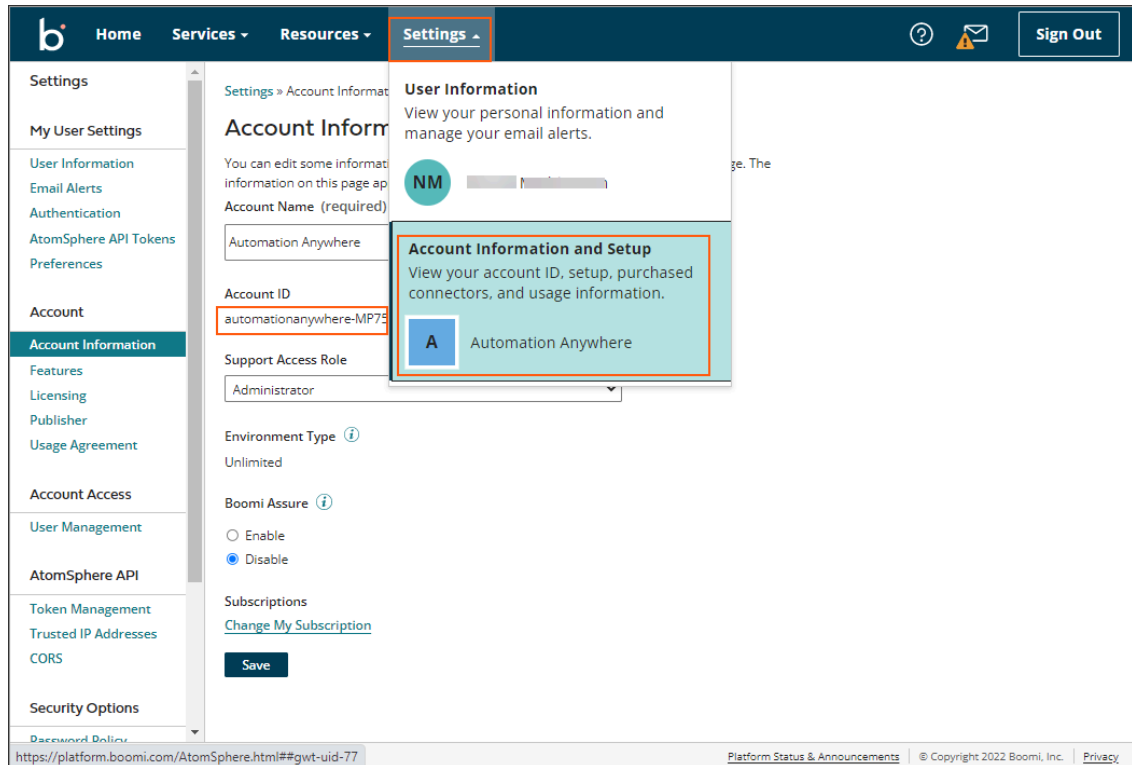

Boomi Session Start action

With the **Boomi Session Start** action, you can connect to a particular Boomi instance using a valid Account ID to begin a session.

Make sure you have an account to log in to the Boomi AtomSphere Platform. If you are new to Boomi, go to the Boomi website at [Boomi Platform](#) and click the Free Trial link on the banner at the top of the page.

1. Log in to the Boomi AtomSphere Platform ([Boomi Platform](#)).
2. Navigate to **Settings > Account Information and Setup**.

You will notice the **Account ID**.

3. Copy the Account ID.
4. Log in to the Automation 360 Control Room.
5. Create a new .
 - a) Log in to your instance of the .
 - b) On the left panel, click **Automation**.
 - c) Click **Create new > Bot**.
 - d) In the **Create Task Bot** window, enter the name.
 - e) Accept the default folder location: `\Bots\`
To change the default storage location, click **Choose** and follow the prompts.
 - f) Click **Create and edit**.
6. From the Actions pane, select **Boomi > Session Start** and place it under the **Start** of the bot flow.

Boomi information	Option
Boomi Account ID/Boomi Login/ Boomi password	<p>Select one of the following options to specify the Boomi Account ID/Boomi Login/Boomi password:</p> <ul style="list-style-type: none"> • Credential: Enables you to use a value available in the Credential Vault that contains information about the Boomi Account ID/Boomi Login/Boomi password. • Variable: Enables you to use a credential variable that contains information about the Boomi Account ID/Boomi Login/Boomi password. • Insecure string: Enables you to enter the Boomi Account ID/Boomi Login/Boomi password for the Boomi Session Start.

- a) In the **Boomi Account ID** field, paste the **Account ID** copied from the Boomi Atomsphere Platform.
- b) In the **Boomi Login** field, enter the Email Address used to log in to the Boomi Atomsphere Platform.
- c) In the **Boomi Password** field, enter the Password used to log in to the Boomi Atomsphere Platform.

The following example shows how **Insecure string** is used for the Session Start information. For better security, you can use either the **Credential** or **Variable** options.

Boomi List Atoms action

With the Boomi List Atoms action, you can list all the Atoms associated with a Boomi instance.

Note: Ensure that you have started a Boomi session before initiating any Boomi action. For more details, see [Boomi Session Start action](#) on page 2329.

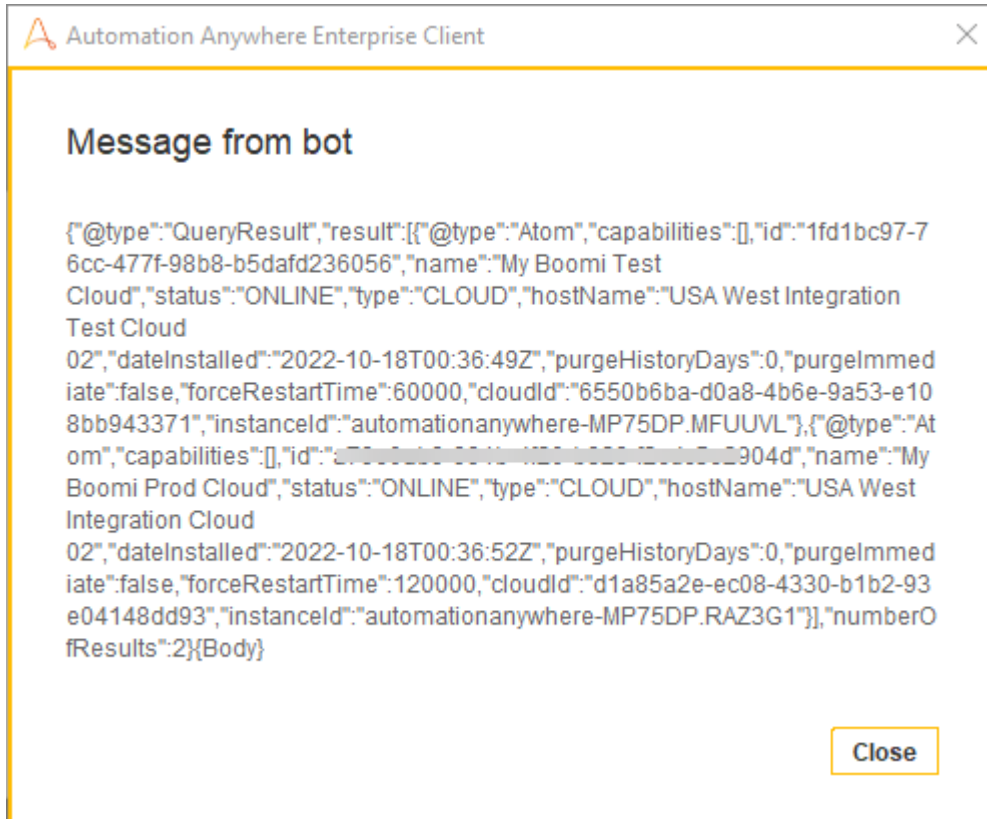

An Atom is a single tenant runtime engine and cannot be used by multiple accounts. It is a light-weight Java application that runs on a single node only and does not provide high availability. The following procedure describes how to list all the Atoms of a Boomi instance:

1. From the **Actions** pane, select **Boomi** > **List Atoms** and place it in the canvas.

The screenshot displays the Boomi automation interface. On the left, a flow diagram shows the sequence of actions: Start, Boomi: Session Start (session start "Default"), Boomi: List Atoms (List Atoms), Message box ("\${jListAtoms}\${Body}"), and End. The 'Boomi: List Atoms' action is highlighted with a red box. On the right, the configuration panel for 'Boomi: List Atoms' is shown, with the 'Session name' field set to 'Default' and the 'JSON Results' field set to 'jListAtoms'.

2. Make sure the **Session name** field is set to Default. Default uses the current session that has been established using the [Boomi Session Start action](#) on page 2329.
3. Create a variable to store the response. In this example, the response is saved in a variable named `jListAtoms`.

You can use a message box action to view the list of Atoms. The message box displays the list of Atoms similar to the following image:

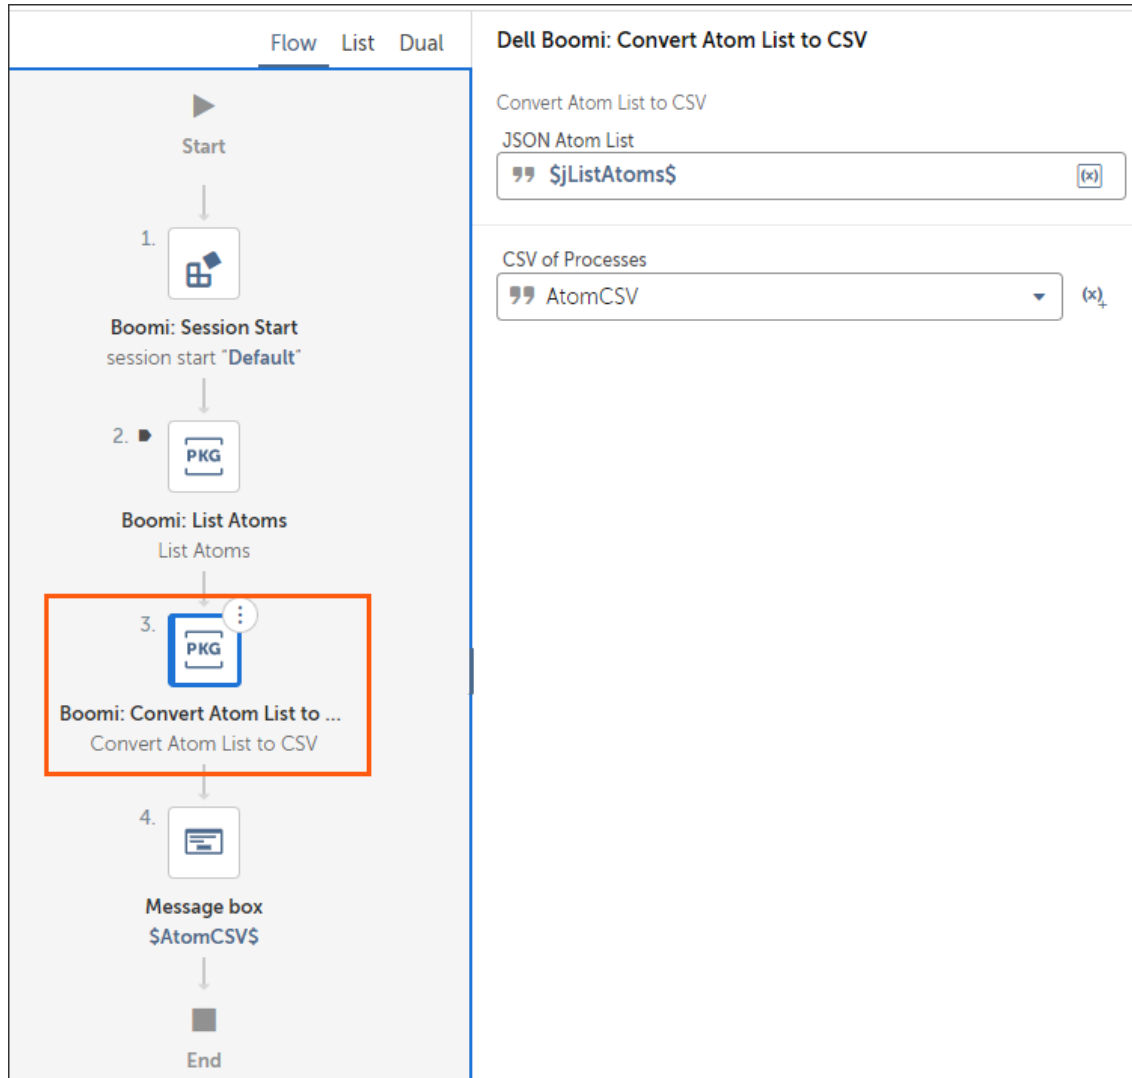

Boomi Convert Atom list to CSV action

With the **Boomi Convert Atom List to CSV** action, you can convert an Atom list associated with a Boomi instance into a CSV format.

Note: Ensure that you have started a Boomi session before initiating any Boomi action. For more details, see [Boomi Session Start action](#) on page 2329.

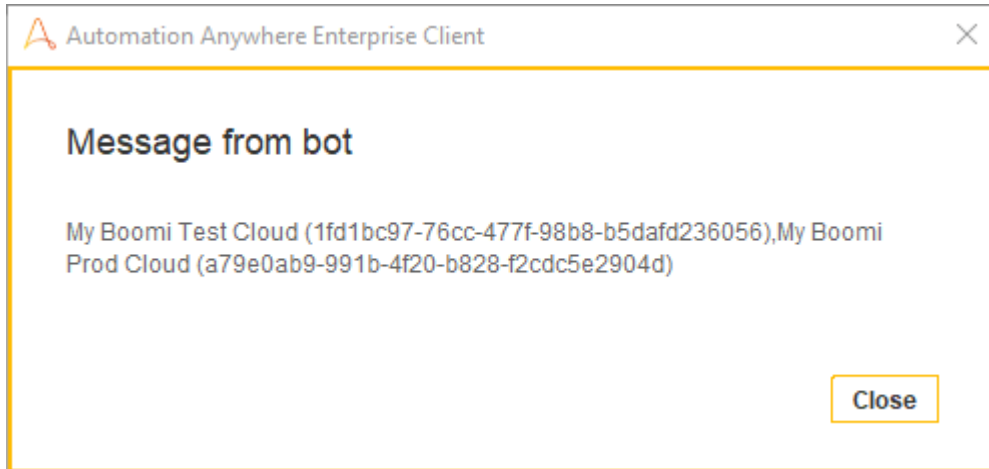

The following procedure describes how to convert an Atom list to CSV in a Boomi instance:

1. From the **Actions** pane, select **Boomi** > **Convert Atom List to CSV** and place it in the canvas.

2. Enter a JSON Atom List stored in a variable. For more information on storing a JSON Atom List, see [Boomi List Atoms action](#) on page 2331.
3. Create a variable to store the response. In this example, the response is saved in a variable named `AtomCSV`.

You can use a message box action, to view the CSV. The message box displays the list of Atoms converted into a CSV similar to the following image:

Boomi List Processes action

With the Boomi List Processes action, you can list all the Processes associated with a Boomi instance. The process is the central component in Boomi Integration.

Note: Ensure that you have started a Boomi session before initiating any Boomi action. For more details, see [Boomi Session Start action](#) on page 2329.

A process is a graphical representation of the path that a document takes from the point at which it is received or retrieved to the point at which it is sent to one or more destinations. Processes in Boomi are depicted with a left-to-right series of shapes and connected together similar to a flow chart. It illustrates the steps required to transform, route, or manipulate the data from the source to the destination. Processes use connectors to retrieve and send data. Processes are deployed to the atom (a dynamic runtime engine). Once processes have been deployed, the atom contains all the components required to execute the integration processes from start to finish including:

- Connectors
- Transformation rules
- Decision handling
- Processing logic

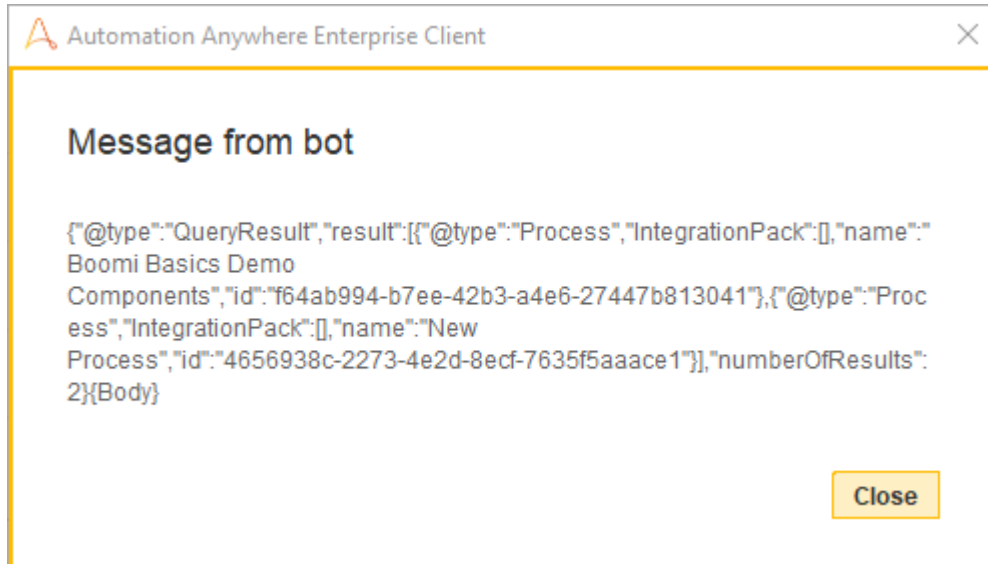

The following procedure describes how to list all the Processes of a Boomi instance:

1. From the **Actions** pane, select **Boomi** > **List Processes** and place it in the canvas.

The screenshot displays the Automation Anywhere interface. At the top, there are buttons for 'Saved', 'Assistant', 'Run', 'Debugger', 'Close', and 'Save'. Below this, the 'Flow' tab is selected, showing a vertical flowchart with three steps: 1. 'Boomi: Session Start' (session start "Default"), 2. 'Boomi: List Processes' (List Processes), and 3. 'Message box' (displaying "\${jListProcesses\${Body}}"). The 'Boomi: List Processes' step is highlighted with a red box. To the right, the configuration panel for 'Dell Boomi: List Processes' is visible, showing the 'List Processes' section with 'Session name' set to 'Default' and 'JSON Results' set to 'jListProcesses'.

2. Make sure the **Session name** field is set to Default. Default uses the current session that has been established using the [Boomi Session Start action](#) on page 2329.
3. Create a variable to store the response. In this example, the response is saved in a variable named `jListProcesses`.

You can use a message box action, to view the list of Processes. The message box displays the list of Processes similar to the following image:

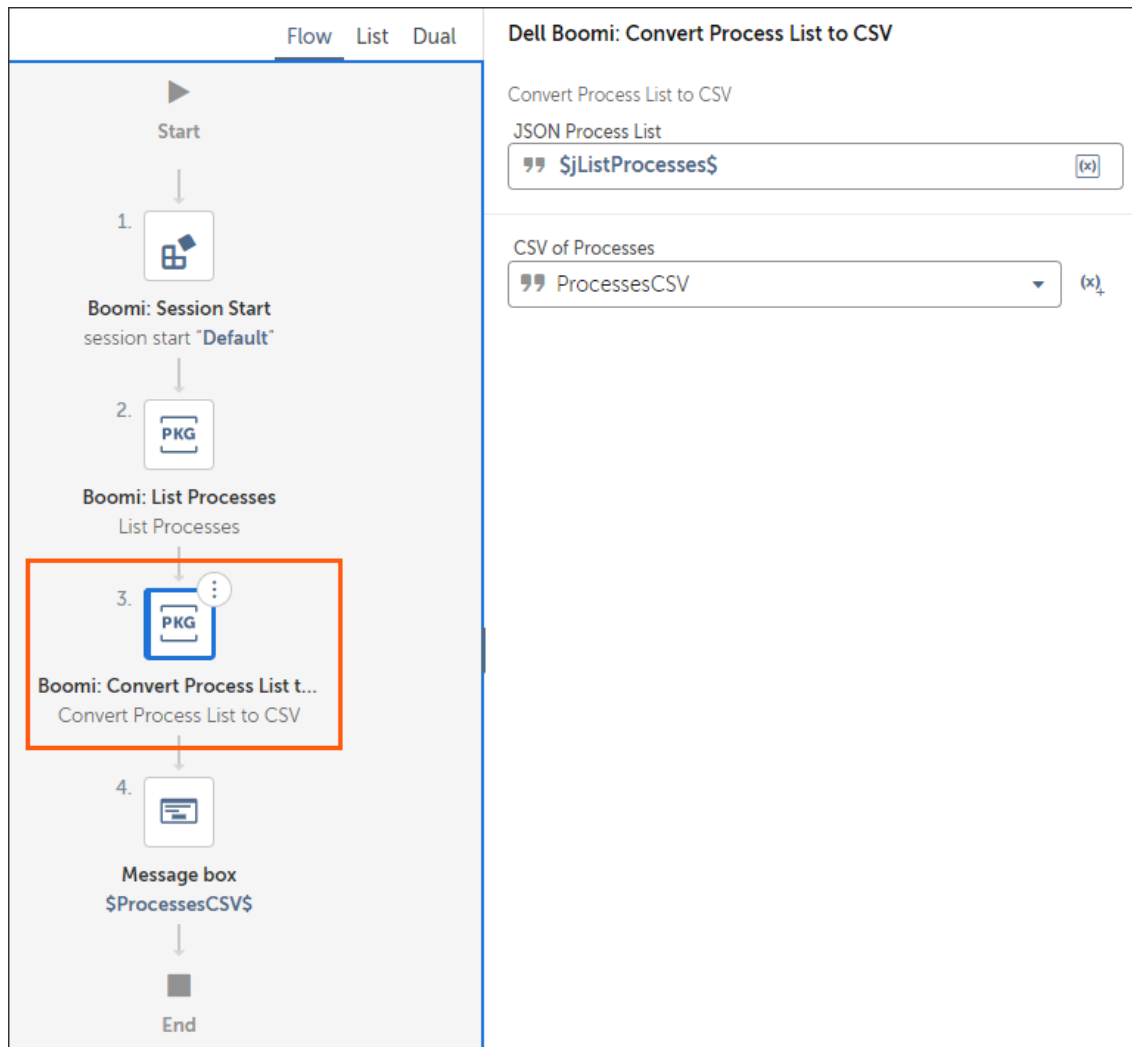

Boomi Convert Process List to CSV action

With the **Boomi Convert Process List to CSV** action, you can convert a Process list associated with a Boomi instance into a CSV format.

Note: Ensure that you have started a Boomi session before initiating any Boomi action. For more details, see [Boomi Session Start action](#) on page 2329.

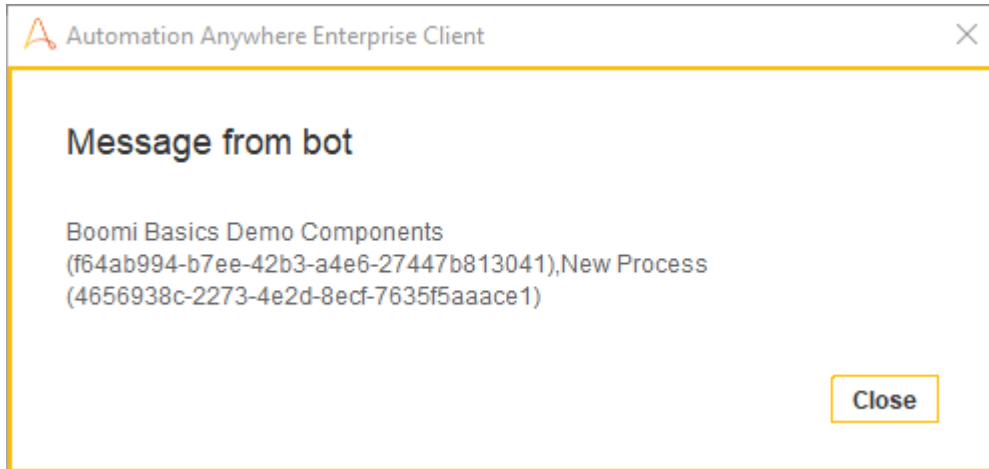

The following procedure describes how to convert a Process list to CSV in a Boomi instance:

1. From the **Actions** pane, select **Boomi** > **Convert Process List to CSV** and place it in the canvas.

2. Enter a JSON Process List stored in a variable. For more information on storing a JSON Processes List, see [Boomi List Processes action](#) on page 2335.
3. Create a variable to store the response. In this example, the response is saved in a variable named `ProcessesCSV`.

You can use a message box action, to view the CSV. The message box displays the list of Processes converted into a CSV similar to the following image:

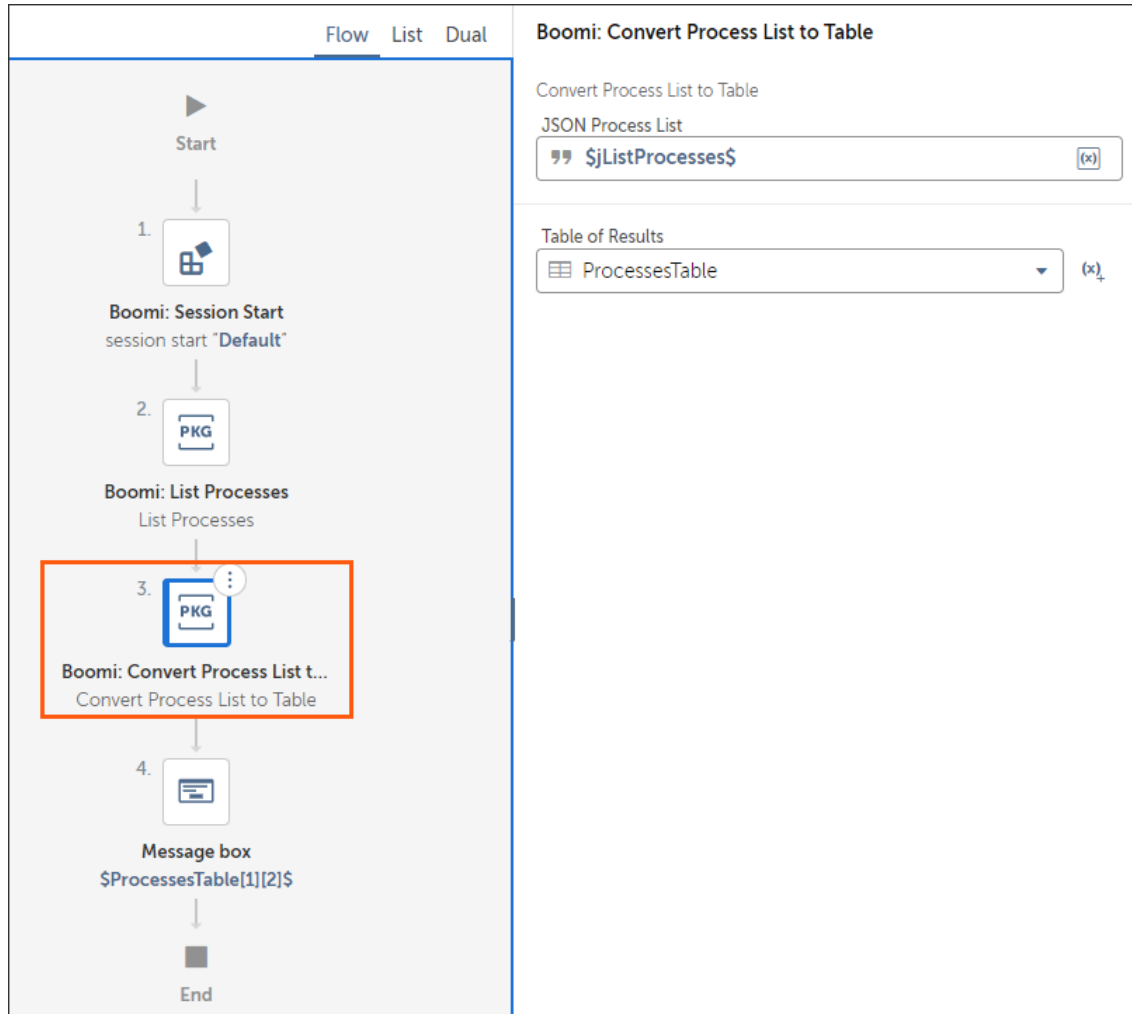

Boomi Convert Process List to Table action

With the **Boomi Convert Process List to Table** action, you can convert a Process list associated with a Boomi instance into a Table format.

Note: Ensure that you have started a Boomi session before initiating any Boomi action. For more details, see [Boomi Session Start action](#) on page 2329.

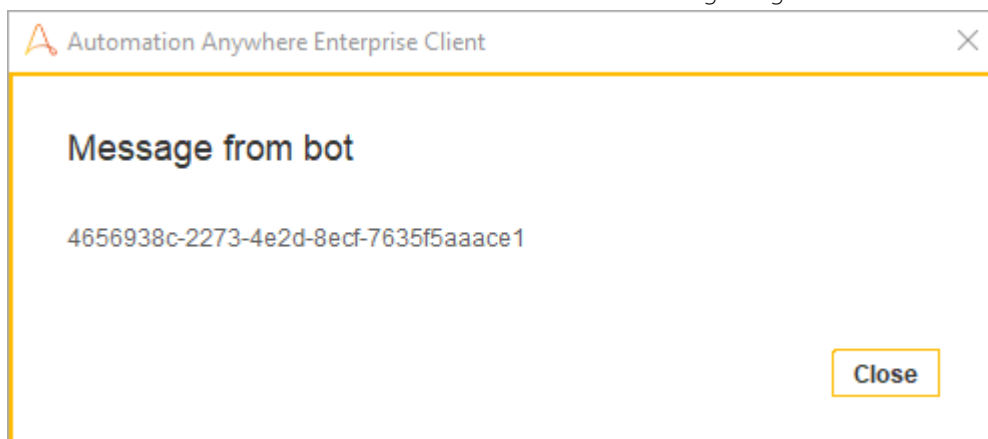

The following procedure describes how to convert a Process list to table in a Boomi instance:

1. From the **Actions** pane, select **Boomi > Convert Process List to Table** and place it in the canvas.

2. Enter a JSON Process List stored in a variable. For more information on storing a JSON Process List, see [Boomi List Processes action](#) on page 2335
3. Create a variable to store the response. In this example, the response is saved in a variable named `ProcessesTable`.

You can use a message box action, to view the CSV. The message box displays a cell from the list of Processes converted into a Table similar to the following image:

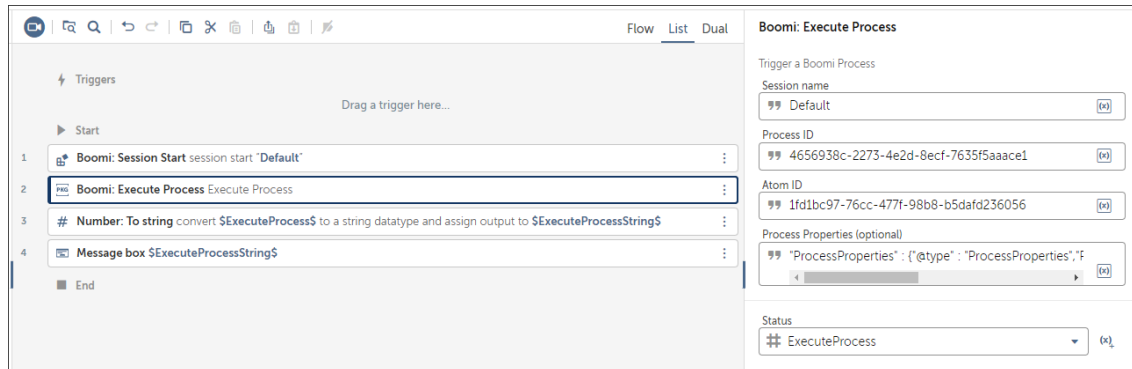

Boomi Execute Process action

With the **Boomi Execute Process** action, you can execute a process associated with a Boomi Atom.

Note: Ensure that you have started a Boomi session before initiating any Boomi action. For more details, see [Boomi Session Start action](#) on page 2329.

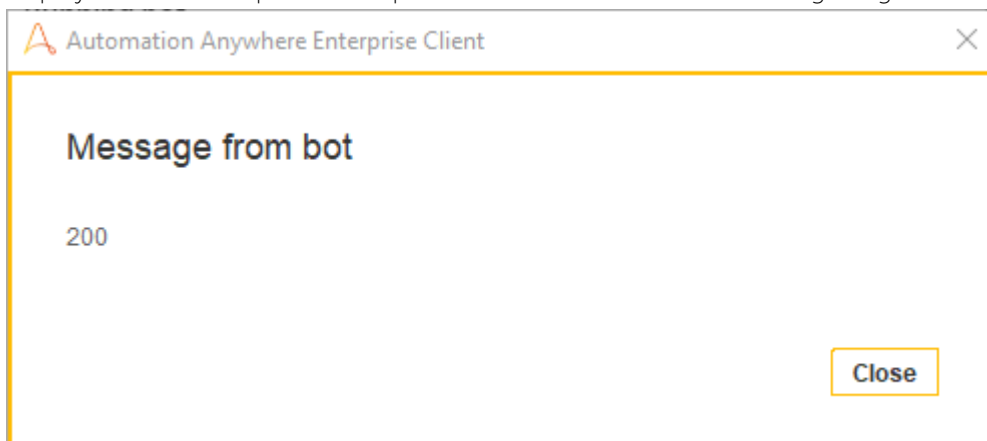

The following procedure describes how to execute a process associated to a Boomi atom:

1. From the **Actions** pane, select **Boomi > Execute Process** and place it in the canvas.

2. Make sure the **Session name** field is set to Default. Default uses the current session that has been established using the [Boomi Session Start action](#) on page 2329.
3. In the **Process ID** field, enter a process ID that you want to execute. For more information on retrieving the process ID, see [Boomi List Processes action](#) on page 2335.
4. In the **Atom ID** field, enter an atom ID to which the process is associated. For more details, see [Boomi List Atoms action](#) on page 2331.
5. In the **Process Properties field (optional)**, enter the process properties you want to edit.

You can save the response into a variable. In this example, the response is saved in a variable named `ExecuteProcess`. Use a message box to view the content of the variable. The API response is converted into a string before it is passed to the message box. The message box displays the execute process response of the similar to the following image:

Boomi List Execution Records action

With the **Boomi List Execution Records** action, you can list all the execution records associated with a Boomi instance.

Note: Ensure that you have started a Boomi session before initiating any Boomi action. For more details, see [Boomi Session Start action](#) on page 2329.

The following procedure describes how to list the execution records of a Boomi instance:

1. From the **Actions** pane, select **Boomi** > **List Execution Records** and place it in the canvas.

The screenshot displays the Boomi automation canvas with the following steps:

1. Start
1. Boomi: Session Start (session start "Default")
2. Boomi: Execute Process (Execute Process)
3. Boomi: List Execution Records (List Execution Records) - This step is highlighted with a red box.
4. Data Table: Write to file ("c:\Temp\test.txt" from data ta...)
- End

The right-hand pane shows the configuration for the **Boomi: List Execution Records** action:

- List Execution Records**
- Session name: Default (x)
- Table of Results: ExecutionRecords (x)

2. Make sure the **Session name** field is set to Default. Default uses the current session that has been established using the [Boomi Session Start action](#) on page 2329.
3. Create a variable to store the response. In this example, the response is saved in a variable named `ExecutionRecords`.

You can use a **Data Table: Write to file** action, to view the execution records.

Boomi Session End

With the Boomi Session End action, you can end an established Boomi session.

Note: Ensure that you have started a Boomi session before initiating any Boomi action. For more details, see [Boomi Session Start action](#) on page 2329.

The following procedure describes how to end an existing session of a Boomi instance:

1. From the Actions pane, select **Boomi > Session End** and place it at the end of the bot flow.

The screenshot displays the Boomi Studio interface. On the left, a workflow diagram shows the following steps: 3. Boomi: List Execution Records (List Execution Records), 4. Data Table: Write to file (writing to 'c:\Temp\test.txt'), and 5. Boomi: Session End (session end 'Default'). The 'Boomi: Session End' action is highlighted with a red box. On the right, the configuration pane for 'Boomi: Session End' shows the 'Session name' field set to 'Default'.

2. Make sure the **Session name** field is set to Default. Default uses the current session that has been established using the [Boomi Session Start action](#) on page 2329.

Boolean package

The **Boolean** package contains actions that enable you to do various operations on boolean values.

Actions in the Boolean package

The actions in the **Boolean** package accept a variable as an input and assign the output to a variable. These actions enable you to compare two boolean values, convert a boolean value to a string or numeric value, and convert a string value to a boolean value.

The **Boolean** package includes the following actions:

Action	Description
Assign	See Assign action in Boolean on page 2345
Compare to	See Compare to action in Boolean on page 2345
Equal to	See Equal to action in Boolean on page 2345
Invert	See Invert action in Boolean on page 2346
To number	See To number action in Boolean on page 2346
To string	See To string action in Boolean on page 2346

Compare results for the Compare to action

The following table illustrates how two boolean values are compared using the **Compare to** action and their output:

Boolean value 1	Boolean value 2	Compare result
True	True	0
True	False	1
False	True	-1
False	False	0

Compare results for the Equal to action

The following table illustrates how two boolean values are compared using the **Equal to** action and their output:

Boolean value 1	Boolean value 2	Equal result
True	True	True
True	False	False
False	True	False
False	False	True

Related reference

[Boolean package updates](#) on page 819

Review the updates in released versions of the Boolean package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Assign action in Boolean

The Assign action in the Boolean package enables you to assign a constant value (True or False) or a user-defined value to a boolean value.

Settings

- In the **Select the source boolean variable/value** field, select one of the following options:
 - **Constant values:** Enables you to assign a constant value (**True** or **False**).
 - **Variable value:** Enables you to assign a user-defined value to a boolean value.
- In the **Select the destination boolean variable** field, select a boolean variable to store the output.

Compare to action in Boolean

The Compare to action in the Boolean package enables you to compare two Boolean values and assigns the output to a number variable.

Settings

- In the **Select the first boolean variable** field, specify a boolean variable.
- In the **Select the second boolean variable** field, specify a boolean variable that the first boolean variable has to be compared with.
- In the **Assign the output to a number variable** field, select a variable to store the output.

Equal to action in Boolean

The Equal to action in the Boolean package enables you to verify whether the two boolean values are equal or not, and assigns the output to a boolean variable.

Settings

- In the **Select the first boolean variable** field, specify a boolean variable.
- In the **Select the second boolean variable** field, specify a boolean variable that the first boolean variable has to be compared with.
- In the **Select the boolean variable to store the result** field, select a variable to store the output.

Invert action in Boolean

The Invert action in the Boolean package enables you to convert a boolean value to the opposite value (True to False and False to True), and assigns the output to a variable.

Settings

- In the **Select the boolean variable to be inverted**, select the boolean value to convert. Choose from **False**, **True**, or a **Variable**.
- In the **Assign the output to** field, select a boolean variable to store the converted value.

To number action in Boolean

The To number action in the Boolean package enables you to convert a boolean value to a numeric value. This action converts True to 1 and False to 0.

Settings

- In the **Select boolean variable** field, select the boolean variable that you want to convert.
- In the **Assign the output to variable** field, select the number variable to store the converted value.

To string action in Boolean

The To string action in the Boolean package enables you to convert a boolean value to a string value.

Settings

- In the **Select boolean variable** field, select the boolean variable that you want to convert.
- In the **Assign the output to variable** field, select the number variable to store the converted value.

Bot migration package

The **Bot migration** package enables you to migrate Enterprise 10 and Enterprise 11 bots to Automation 360 format. The package also enables you to convert Enterprise 10, Enterprise 11, or Automation 360 bots that use Internet Explorer to Microsoft Edge with IE mode. This package is used internally by the Bot Migration Wizard and the Update Bot wizard.

See [Supported Control Room versions for migration](#) on page 1446.

Important: We recommend that you use the Bot Migration Wizard to migrate Enterprise 11 or Enterprise 10 bots to Automation 360.

The **Bot migration** package does not migrate dependencies and other entities such as credential variables, AAAApplicationPath system variable, and global values that are required to run the migrated bot.

Action in the Bot migration package

The **Bot migration** package includes the following action:

Action	Description
Migrate legacy bot	See Migrate legacy bot action .
Update bot	See Update bot action .

Related concepts

[Migrate to Automation 360](#) on page 1436

Migration (upgrade) is the process of moving your data and bots from Enterprise 11 or Enterprise 10 to Automation 360. Migration includes but is not limited to replicating and updating your existing database and repository, converting your bots to the Automation 360 format, and migrating learning instances for IQ Bot and dashboards for Bot Insight.

Related reference

[Bot Migration package updates](#) on page 820

Review the updates in released versions of packages such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Migrate legacy bot action in Bot Migration

The Migrate legacy bot action enables you to migrate the Enterprise 11 and Enterprise 10 bot files to Automation 360 format.

Settings

Starting from Automation 360 v.24R2 release for IE EOL, the **Migrate bot** action is renamed as **Migrate legacy bot**.

This action only migrates the bot you specify, but does not migrate its dependencies. Dependencies are the bots and other files that are required to run the bot. You must migrate the dependent bots separately and upload other files manually to Control Room.

All the bots migrated using the **Bot migration** package are stored in the **Bots** folder in Automation 360. If you have to migrate a parent bot and its child bots separately using the **Bot migration** package, you must create the same folder structure as in Enterprise 11 or Enterprise 10 and move the dependent bots to these folders for the parent bot to run successfully.

- Use the **Control Room file**, **Desktop file**, or **Variable** tab to specify the location of the bot you want to migrate.
- In the **Output folder path** field, specify the location where you want to save the log files generated for the bot migration.

Note: Ensure that the location you have specified exists on the device.

The system does not upload the bot if it fails during the migration process. The system creates an XML report at the same location that provides information that helps you to troubleshoot if the system encounters an error during migrating the bot file.

- Select the **Overwrite the file if exists** check box to overwrite an existing bot file.
- Set a time-out value for migrating the bots within the range of 3 through 90 minutes (default value is 90 minutes).

If the migration of any specific bot is not completed within the set time, the bot will display a timeout message with the reason for the failure and the migration process will move on to the next bot.

- If you are migrating Enterprise 10 and Enterprise 11 bots that are built using Internet Explorer, select the **Convert bots built using Internet Explorer to Edge with Internet Explorer mode** option to convert them to Microsoft Edge with IE mode.

Update bot action in Bot Migration

The **Update bot** action enables you to convert Automation 360 bots that are built using Internet Explorer browser to Microsoft Edge Chromium with IE mode.

Settings

This action is internally used by the Update Bot wizard to convert the bots .

Note: This action cannot be used manually in a new or an existing bot for bot conversion.

- From the **Select task bot file** field, enter the name of the Task Bot file that you want to upload or select an existing used variable.
- From the **Select bot version to update** option, select either the latest version of the bot or the bot version that is provided on the production label.

Browser package

The Browser package contains actions that enable you to download files, find broken links, and launch a website. This package supports Google Chrome, Chromium-based Microsoft Edge, and Internet Explorer browsers.

Actions in the Browser package

The Browser package includes the following actions:

Action	Description
Call a JavaScript function	See Call a JavaScript function action on page 2349
Close	See Close action on page 2351

Action	Description
Download files	See Download file action on page 2353
Find broken links	See Using Find broken links action on page 2353
Get source code	See Get source code action on page 2354
Go back	See Go back action on page 2354
Open	See Open action on page 2355
Run JavaScript	See Run JavaScript action on page 2358

Note:

- When you create a bot using the **Call a JavaScript** or **Run JavaScript** actions and want to execute the same Javascript you ran earlier using the **Run JavaScript** action, the bot displays an error.

To resolve this issue, see the workaround provided in [Call a JavaScript or Run JavaScript actions display an error \(A-people login required\)](#)

- When you perform any action from the Browser package on the Internet Explorer browser tab, if multiple tabs with the same tab title are opened in the same browser window, the matching title is not searched in sequence starting from the first tab. The tab activation and browser action might be performed on different matching tabs in sthis case.
- If the same tab title occurs on different windows, then the action is executed on a tab with a matching title in any window.

Related reference

[Browser package updates](#) on page 821

Review the updates in released versions of the Browser package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Call a JavaScript function action

The Call a JavaScript function action in the Browser package enables you to call an existing JavaScript function directly in a webpage or in an iFrame within a webpage.

Configure the settings

Note: This action supports Google Chrome and Chromium-based Microsoft Edge browsers.

- Select the browser tab from the list of active supported browser tabs or insert a window variable.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `(\w*) -Notepad` for all window title names starting with `(\w*) -Notepad`, or use **Pattern** value as `(\w)\s*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

2. Optional: Use the **Capture object** option to capture the iFrames.
-

Note: You can use the **Capture object** feature to call and run an existing JavaScript function inside an iFrame.

3. In the **Function name** field, specify the name of the existing JavaScript function that you want to call.
 4. Optional: In the **Arguments** section, click **Add argument** to add arguments that must be passed to call the JavaScript function.
 - a) In the **Argument details** dialog box, select the **Argument type** required for the specific argument.
 - b) In the **value** field, enter the corresponding value or variable of the selected type that you want to pass.
-

Note: All string values in arguments are passed as is without any character being converted or escaped.

5. Optional: In the **Time out after** field, enter the number of seconds the bot must wait for the browser action to complete.
-

Note: Enter a timeout value of at least 9 seconds.

6. In the **Return Type** field, select the type of value returned by the JavaScript function.
-

Note: If the function does not return anything, in the **Return Type** field, select **None**.

7. For any **Return type** except **None**, in the **Save the outcome to a variable** field, select a variable for selected **Return type** to hold the JavaScript function output.
-

Create variable

To create a variable for selected **Return type**, perform the following steps:

1. Click the Create variable symbol next to the **Save the outcome to a variable** field.
A **Create variable** dialog opens with default variable name for the type of variable selected.
2. Optional: Specify the variable information in the **Description** field.
3. Optional: Specify a value in the **Default value** field.
4. Click **Create & select** to select the newly created variable.

Supported JavaScript types in Argument and Return type fields

The following JavaScript types are supported:

- String, Number, and Boolean JavaScript types which correspond to the same variable types in bot variables.
- Array JavaScript type which corresponds to the List variable type in bot variables.
- Object JavaScript type which corresponds to the Dictionary variable type in bot variables.

Close action

Use the Close action in the Browser package to close a browser window or tab.

Settings

Note: This supports , Chromium-based , and browsers.

- Select to close the tab, window, or all browsers:
 - **Tab:** Closes the selected tab. Select the browser tab from the list of active supported browser tabs or insert a window variable.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*) -Notepad)` for all window title names starting with `((\w*) -Notepad)`, or use **Pattern** value as `((\w)\s)*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

-
- **Window:** Closes the window of the selected tab. Select the window from the list of active supported windows or insert a window variable.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `(\w*)-Notepad` for all window title names starting with `(\w*)-Notepad`, or use **Pattern** value as `(\w)\s)*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

-
- **All browsers:** Closes all open browser windows for supported browsers.
 - Optional: In the **Time out after** field, enter the number of seconds the bot must wait for the browser window or tab to close before the bot fails.

Note: Enter a timeout value of at least 9 seconds.

Download file action

The Download file action in the Browser package downloads and saves a file from the specified URL that might require NTLM authentication.

Note: This action downloads only a single file to the specified file location.

Settings

- Specify the **URL of the file** you want to download.
- In the **Save to location** field, enter the location where you want to save the file.

Using Find broken links action

The **Find broken links** action finds broken links on a specific page or website, stores the output to a CSV file. Optionally, you can specify encoding for the output data.

Follow these steps to find broken links:

1. In the Actions palette, double-click or drag the **Find broken links** action from the Browser package.
2. In the **Page or URL** field, enter the URL of the page or website.
3. In the **Scope** option, choose either **check only this page** or **check the whole site**.
4. In the **Save list to location** field, specify the location of the CSV file.
5. Select the **Append to already existing csv file** check box if you want to append the data to an existing CSV file.
6. Select an option from the **Encoding** list to specify the encoding that you want to apply on the file.
 - **ANSI**
 - **Unicode**
 - **UTF-8**
7. In the **Number of parallel threads** field, enter the number of parallel threads you want to run simultaneously.

Parallel threads means multiple processes running simultaneously to perform the same task which results in faster execution. Higher the number of parallel threads faster the execution of a task execution. For example, if 10 threads complete a task in two minutes, 20 threads complete a task in one minute.

Note: The maximum value you can provide in the field is 99.

8. In the **Time out** field, specify the maximum time the system must wait to receive a response from each URL link.
9. Click **Save**.

Get source code action

The **Get source code** action retrieves the source code of a web page and an iFrame on a web page and saves the output to a string variable.

Settings

Note: This supports , Chromium-based , and browsers.

- Select the browser tab from the list of active supported browser tabs or insert a window variable.
 - Optional: Use the **Capture object** option to capture the iFrames.
-

Note:

- The **Capture object** feature is used only to retrieve the source code of an iFrame. If you do not capture anything on the window, the source code of the entire window is retrieved.
 - Retrieving the source code of an iFrame is currently supported only on the Google Chrome browser.
-
- Optional: In the **Time out after** field, enter the number of seconds the must wait for the browser action to complete.
-

Recommended: Enter a timeout value of at least 9 seconds.

- Optional: Select a variable to hold the output. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Go back action

The **Go back** action returns to a web page previously visited in the current tab. This action simulates clicking the browser **Back** option.

Settings

Note: This supports , Chromium-based , and browsers.

- Select the browser tab from the list of active supported browser tabs or insert a window variable.
-

Note: When you select the Internet Explorer tab from the list of active tabs, and if the selected tab title or any intermediate tab title while performing the **Go back** action has more than 60 characters, then the first 60 characters are used for comparison to find the matching tab title.

Recommendation: When you perform the action on the browser tab, ensure that only a single tab is open in the browser window with the matching tab title. This setting ensures that when

the action is executed, there is no intermediate tab title that matches another tab title in the same window.

- In the **Number of steps back** field, enter the number of pages to go back to.
- **Optional:** Select the **Throw an error if steps exceed history** option so that the bot will fail if the number entered in the previous step is greater than the number of pages visited.

If this option is not selected, when the bot runs, it will return the tab to the first web page it opened.

- **Optional:** In the **Time out after** field, enter the number of seconds the bot must wait for the browser action to complete.

Recommended: Enter a timeout value of at least 9 seconds.

Open action

The **Open** action opens the browser to a specific web page.

Using network path URLs

When you use network path URLs, you might encounter bot errors in the following scenarios:

- When you open a network file path using the **New tab**, **Existing tab**, or **New window** option in the Internet Explorer browser.
- When you open a network folder path using the **Existing tab** option in the Internet Explorer or Chromium (Google Chrome or Microsoft Edge) browsers.

To fix these errors with network file or folder path, perform one of the following steps as required:

- For network file path, select a Chromium browser (Google Chrome or Microsoft Edge) in the action.
- For network folder path, select a Chromium browser (Google Chrome or Microsoft Edge) in the action with **New tab** or **New window** option.

Settings

Note:

- This action is used only to open a URL in the browser. You cannot download a file using this action.
- This action does not support InPrivate or Incognito mode of browsers.

-
- Select to open the web page in an existing tab, new tab, or new window:
 - **Existing tab:** Opens the web page on a currently open tab. Select the tab from the list of active supported browser tabs, the **Last used browser tab** option, or insert a window variable.

Note: This option supports , Chromium-based , and browsers.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*) -Notepad` for all window title names starting with `((\w*) -Notepad`, or use **Pattern** value as `((\w) \s) *document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

- **New tab:** Opens the web page on a new tab. Select the tab from the list of active supported browser tabs or insert a window variable.
-

Note:

- This option supports Google Chrome, Chromium-based Microsoft Edge, and the Internet Explorer browsers.
 - When you perform the action on the Internet Explorer tab, the action is executed in the matching tab only when it is in ready state.
-

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*) -Notepad` for all window title names starting with `((\w*) -Notepad`, or use **Pattern** value as `((\w) \s) *document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

-
- **New window:** Opens the web page on a new window of a specific browser.

Select the browser from the following options:

- Default Browser

Ensure that Google Chrome, Microsoft Edge or Internet Explorer is set as the default browser.

Note: If any browser that is not listed is set as the default browser for the device, the bot might encounter an error.

-
- Google Chrome
 - Internet Explorer
 - Microsoft Edge
 - Mozilla Firefox

- Enter the link to the web page to open.

Note: For web pages to open properly, we recommend that you specify a URL with the protocol information, such as http, https, or file.

-
- Optional: In the **Time out after** field, enter the number of seconds the bot must wait for the specified webpage to load before the bot fails.

Note:

- You can enter a timeout value of at least 9 seconds.
 - Timeout value is applicable only for the **New tab** and **Existing tab** options.
 - For the Internet Explorer browser, the bot executes even if the webpage is not loaded completely after waiting till timeout.
-

Run JavaScript action

The **Run JavaScript** action in the Browser package executes JavaScript on a web page and on web pages that have iFrames.

Settings

Note:

- This action supports Google Chrome and Chromium-based Microsoft Edge browsers.
 - When you use this action to execute a JavaScript that contains a single-line comment as the last line of the JavaScript (for example, `//comment`), it can cause the Automation Anywhere plugin to become unstable. We recommend that you either remove the comment at the end of the JavaScript or convert it to a multi-line comment (for example, `/* comment */`).
-

- Select the browser tab from the list of active supported browser tabs or insert a window variable.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `(\w*) -Notepad` for all window title names starting with `(\w*) -Notepad`, or use **Pattern** value as `(\w)\s*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

- Choose one of the following options:

- In the **Import existing file** option, select an existing file.
-

Note: If you are uploading a script from a file on your desktop, the file and any dependencies must be in a standalone folder. When you select a file for upload, all files and folders at the same folder level are uploaded.

- In the **Manual input** option, enter the .
- Optional: Use the **Capture object** option to capture the iFrames.

Note:

- The **Capture object** feature is used only to run JavaScript inside an iFrame.
 - Support to run JavaScript inside an iFrame is available only for the Google Chrome browser.
-
- Optional: In the **Time out after** field, enter the number of seconds the must wait for the browser action to complete.

Recommended: Enter a timeout value of at least 9 seconds.

- Optional: In the **Save the outcome to a variable** field, select a variable to hold the action output. The Control Room shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Note: This action supports String, Number, and Boolean JavaScript types which correspond to the same variable types in bot variables, or to the bot variable type Any.

Recommendation:

- Do not use JQuery with the JavaScript package.
- Use the **Try/Catch** actions from the Error handler in the JavaScript function.
- Call a JavaScript function before declaring it.

Watch the following video on using the Run JavaScript action from the Browser package to execute JavaScript directly within an existing browser window:

Automating object-based applications

We recommend that you use the Recorder for object-based automations instead of Run JavaScript action. If you use Run JavaScript action to automate dynamic web pages and if there is a change in control hierarchy or properties, then you must re-write the entire script. Use the Run JavaScript action only to execute external scripts in any application.

You can use the Recorder to automate applications using other available technologies if you are unable to capture using the default HTML technology. Ensure that the accessibility for your application is enabled and is not blocked by any company policy before you use a different technology to automate. We recommend you open Google Chrome with the flag `--force-renderer-accessibility`.

Accessibility Internals

Use this page to inspect the internal representation of accessibility in Chrome. You can see and modify the various accessibility modes Chrome has. You can also view the accessibility tree for a specific page, or for the Chrome app natively.

Accessibility modes:

Check/uncheck accessibility modes to see how they change a page's accessibility.

- Native accessibility API support**
Allows Chrome to be controlled via native accessibility APIs specific to this platform.
- Web accessibility**
Accessibility support is enabled for web content.
- Text metrics**
Enables support for querying line breaks and the bounding box of arbitrary character ranges.
- Screen reader support**
Exposes accessibility APIs typically needed only by screen readers.
- HTML**
Exposes HTML tag names and attributes via accessibility APIs.

Accessibility tree viewing options:

Internal
Show internal accessibility tree instead of native

Filters:

Use filters to match the attributes and attribute values you want included in the output. Filters can contain simple wildcards (*) only, they're not regular expressions. Attributes are separated by spaces.

Allow:
Include these attributes. Empty attributes are skipped.

Allow empty:
Include these attributes, even if they are empty.

Deny:
Exclude these attributes.

Command line options:

Accessibility features in Chrome are off by default and enabled automatically on-demand. Changes to these modes only take effect until the next time Chrome is restarted.

To force accessibility to be enabled at launch, run Chrome with this flag:
`--force-renderer-accessibility`

To disable accessibility, run Chrome with this flag:
`--disable-renderer-accessibility`

Clipboard package

The Clipboard package contains actions that enable you to automate using the Windows clipboard. Use the actions to copy a string value to the clipboard, copy the clipboard value to a string variable, and clear the clipboard.

Actions in the Clipboard package

The Clipboard package includes the following actions:

Action	Description
Clear	See Clear action in Clipboard on page 2361.
Copy from	See Copy from action in Clipboard on page 2361.
Copy to	See Copy to action in Clipboard on page 2361.

Related reference

[Clipboard package updates](#) on page 822

Review the updates in released versions of the Clipboard package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Clear action in Clipboard

The **Clear** action in the Clipboard package enables you to clear the clipboard.

Settings

This action will remove any value that is stored in the clipboard.

Copy from action in Clipboard

The **Copy from** action in the Clipboard package enables you to retrieve the values stored in the clipboard.

Settings

This action enables you to retrieve the values stored in the clipboard and store it in the string variable that you select from the **Assign the output to variable** list. This action also enables you to pass the value from the clipboard to other actions.

Copy to action in Clipboard

The **Copy to** action in the Clipboard package enables you to store values in the clipboard.

Settings

You can either enter the value or specify the string variable that contains the value in the **Value** field.

Credential package

In the Credential package, use the **Assign** action to assign an insecure string or a variable value directly to the credential variable.

Actions in the Credential package

The Credential package includes the following action:

Note:

- The credential variables support the retry mechanism. When you create a bot that uses credential variables, if the bot fails during run time to retrieve those variables from the Credential Vault because the Control Room is disconnected or the Control Room services

stop intermittently, then the bot tries three times to retrieve the credential variables from the Credential Vault.

- While the **Convert credential to string** action is listed on the Credential package details page, it is not available for use from the actions list in the Bot editor. This is because the action should be used only for migration and not for other scenarios because it introduces a security risk.

Action	Description
Assign	<p>Sets the value of a credential variable.</p> <ul style="list-style-type: none"> • You can select Credential to use a value from the Credential Vault, Variable to use a credential variable, or Insecure string to manually enter a variable. • In the Save the outcome to a variable field, select a variable to hold the returned value.

Review the updates in released versions of the Credential package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

CSV/TXT package

The **CSV/TXT** package contains actions that enable you to open a CSV or text file, read data from that file, and assign the data to a Table variable. This package supports files encoded in ANSI, Unicode, UTF-8, or Windows-1251, and can process up to one million records.

Perform the following actions within the **CSV/TXT** package as part of using the set of available actions:

1. Open the file to be used in the automation. See [Using the Open action for CSV/TXT file](#) on page 2363.

Note: For files containing large data sets, use actions from the Database package to automate create, read, and update operations. See [Using Connect action for database](#) on page 2382.

2. Use the **Read** action to retrieve values from a CSV or TXT file and store them in a Table variable. See [Using Read action](#) on page 2364.

To retrieve values row by row, use the **For each row in CSV/TXT** iterator in the Loop action to read values from each row in the file and assign it to a record variable. See [Using the For each row in CSV/TXT iterator](#) on page 2690.

Note: The **Read** action and **For each row in CSV/TXT** iterator only support CSV/TXT files that conform to the RFC 4180 standard. For more information about the standard, see [Common format and MIME type for CSV files](#).

3. After you have automated the CSV/TXT-related tasks, close the file using the **Close** action. Enter the session name that was used to open the file with the **Open** action.

Related reference

[Loop package](#) on page 2679

Use the Loop package to run a sequence of actions repeatedly for a specific number of times or until a specific condition is met.

[Your variables \(user-defined\)](#) on page 2241

Users and some actions create user-defined variables to temporarily hold values. Use this kind of variable to input values into an action (window title, login credential, or file path) or to accept the output of an action (values read from a file or a Boolean return).

[CSV/TXT package updates](#) on page 825

Review the updates in released versions of the CSV/TXT package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using the Open action for CSV/TXT file

This action enables you to specify the delimiter used in the file, whether to trim the spaces, and the encoding applied on the file.

Note: If there is a double quotation mark (") in the last element of the last line of the CSV/TXT file, at runtime the bot will encounter an error.

To open a CSV or text file, do the following:

1. Double-click or drag the **Open** action from the **CSV/TXT** package in the **Actions** palette.
2. Select any of the following options to specify the location of the CSV or text file to open:

- **Control Room file:** Enables you to open a file from the .
- **Desktop file:** Enables you to open a file from the device. This field also accepts the file path input as a string variable or global value.

Note: When you enter a file path in the **Desktop file** field or browse a particular file from the system, wherein the file path is separated by the \ character and save the , the \ character is changed to / as the uses / to separate file paths. Your continue to run successfully even if the \ is changed to / during execution.

- **Variable:** Enables you to open a file by specifying a file variable.
3. Select the **Contains header** check box if the file contains a header row and you want to retrieve values from that row.
 4. Select any of the following options to specify the **Delimiter** used in the file:
 - **Comma**
 - **Tab**
 - **Regional list separator:** Enables you to specify the delimiter as configured in the regional settings of the Windows operating system. If the **List Separator** in the Windows regional settings is modified, then the CSV file should also contain that character as a delimiter.
 - **Newline**
 - **Other:** Enables you to specify a delimiter other than the options listed above.

5. Select the **Trim leading** and **Trim trailing** check boxes to remove the leading and trailing spaces from the data extracted from the CSV/TXT file
6. Select an option from the **Encoding** list to specify the encoding that is applied on the file. Data from the CSV/TXT file will be retrieved based on the selected encoding option even if the input file has a different encoding.
 - **ANSI**: Used to encode Latin alphabet.
 - **UTF8**: Can encode all possible characters.
 - **UNICODE**
 - **Win1251**: used to encode languages that use the Cyrillic script, including Bulgarian, Russian, and Serbian.
 - **UTF-16LE**: ignores the byte order mark (BOM) Unicode character at the beginning of file.
 - **Default**: identifies file encoding. This option supports UTF-8, UTF-16LE, and UTF-16BE file encoding.

Note: Shift-JIS files must use **ANSI** as encoding to read text file content.

7. Click **Save**.

Use the **Read** action to retrieve the data from CSV/TXT file and assign them to a table variable. You can use the loop action to retrieve each row of data from the file or table variable and assign them to the record variable for further operations.

- [Using Read action](#) on page 2364
- [Using the For each row in CSV/TXT iterator](#) on page 2690

Using Read action

Use the **Read** action to retrieve values from a CSV or TXT file, and insert them into a Table variable to perform operations with the data values.

Note:

- The **Read** action only support CSV/TXT files that conform to the RFC 4180 standard. For more information about the standard, see [Common format and MIME type for CSV files](#).
- When you use the **Read** action to read data from a CSV or TXT file that contains double quotes, the bot might display an error message: `Unable to read the file and create a table`. We recommend that you replace all double quotes with an empty or a blank character.

To retrieve values from a CSV or TXT file, do the following:

1. Double-click or drag the **Read** action from the **CSV/TXT** node in the **Actions** palette.
2. Enter the name of the session that you have used to open the CSV or text file in the **Open** action.
3. Select a Table variable from the **Assign value to the variable** list.
Create a variable if it does not already exist. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Note: A bot can return only a maximum of 3 MB to an output variable.

Workaround: Store the bot output on the device, such as in a .txt file. If the output must be shared across multiple Bot Runners, store the output in a shared drive.

Perform operations with the values in the Table variable using the [Data Table package](#) on page 2365.

Comment package

Use the `Comment` package to insert a user-specified comment into your bot logic.

Action in the Comment package

The `Comment` package includes the following action:

Action	Description
Comment	<p>Inserts a comment.</p> <hr/> <p>Note: A comment is saved and displayed as a single line. A comment with multiple lines is displayed as a single line, followed by an ellipsis when the comment is saved. Comments are ignored when the bot runs.</p> <hr/>

Related reference

[Comment package updates](#) on page 823

Review the updates in released versions of the `Comment` package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Data Table package

The `Data Table` package contains actions that enable you to perform various operations on the values of table variables. Use these actions to join or merge content, search for specific values, insert rows and columns, remove duplicate rows, and write values to a file.

Actions in the Data Table package

The `Data Table` package includes the following actions:

Note: If you built a bot using actions from the `Data Table` package from Build 5322 or earlier, the actions will be missing when you open the bot with the default package version. You must reinsert the actions and repopulate the fields.

Action	Description
Assign	Assign action on page 2367.

Action	Description
Change column type	Change column type action on page 2367.
Clear content	Clear content action on page 2368.
Delete column	Delete column action on page 2368.
Delete row	Delete row action on page 2368.
Get number of columns	Get number of columns action on page 2369.
Get number of rows	Get number of rows action on page 2369.
Insert column	Insert column action on page 2369.
Insert row	Insert row action on page 2371.
Join	<p>Using Join action on page 2372.</p> <p>Use the Join type output examples on page 2373 to help you decide whether to use the Join or Merge action.</p> <hr/> <p>Note: If you built a bot using this action from package version 2.0.0-20200624-042148 or earlier, the action will be missing when you open the bot with the default package version. You must reinsert the action and repopulate the fields.</p> <hr/>
Merge	<p>Using the Merge action on page 2375.</p> <p>Use the Merge output example on page 2375 to help you decide whether to use the Join or Merge action.</p> <hr/> <p>Note: If you built a bot using this action from package version 2.0.0-20200624-042148 or earlier, the action will be missing when you open the bot with the default package version. You must reinsert the action and repopulate the fields.</p> <hr/>
Remove duplicate rows	Remove duplicate rows action on page 2377.
Search for a value	Search for a value action on page 2377.
Set value of a single cell	Set value of a single cell action on page 2378.
Sort	Sort action on page 2378.
Write to file	Using Write to file action on page 2378.

Example: [Example of extracting data from a web table](#) on page 3071

Related reference

[Data Table package updates](#) on page 826

Review the updates in released versions of the Data Table package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Assign action

The **Assign** action in the Data Table package enables you to assign values to a table variable.

Settings

You can use this action to manually enter the table data.

- Use the **Source data table** field to select one of the following options:
 - **Table with values:** select one of the following tabs:
 - **Table:** Click **Edit table (1X1)** button to manually add rows and columns.
 - **Variable:** To select a source table variable.

Consider a scenario where you want to change or update some data in an existing database. In order to ensure you do not lose the original data, you can store the existing values as a temporary Datatable variable. You can then use the **Assign** action to create a temporary or duplicate Datatable for making changes.

- **Table with no values:** update the following fields:
 - **Number of rows:** enter the number of rows that you want to assign to the table.
 - **Number of columns:** enter the number of columns that you want to assign to the table.
- Click the **Save the outcome to a variable** drop-down to select a table variable to hold the output.

You can either select the source table variable to overwrite the values, or select a different table variable.

Change column type action

The Change column type action in the Data Table package enables you to change the data type of a column.

Settings

- Select the data table name from the drop-down list.
- Select whether to specify the column by **Name** or **Index**.
 - If you select to specify by name, enter the column name.
 - If you select to specify by index, enter the column index. For example, to set a value to the first column, enter 0.
- Select the new column data type from the drop-down list to **Number**, **Boolean**, **String**, or **Datetime**.

- If you select **Datetime**, you can format the values by selecting a predefined format or specifying a custom format.
- To specify the format applied on the input data table variable, select an option either from the predefined format list or enter the value in a custom format.
- Select a table variable to include the output.
You can either select the source table variable to overwrite the values or select a different table variable.

Clear content action

The Clear content action in the Data Table package enables you to clear the contents of the specified table variable.

Settings

This action clears the content until the execution of the bot is completed. After the bot execution is completed, the original values of the table variables are restored.

This action enables you to reuse an existing table variable to store values that are used only during the bot execution.

Note: The data type of the values must be same as the data type of the columns in the table variable.

Delete column action

The Delete column action in the Data Table package enables you to delete a specific column.

Settings

- Select the Table variable name from the drop-down list.
- Specify the column name or column index to delete.

Note: The index count starts from 0.

Delete row action

The Delete row action in the Data Table package enables you to delete a specific row.

Settings

Note: If the data table values were read from an Excel sheet, and you selected the **Sheet contains a header** option in the **Open** action, you cannot delete cells from the first row.

- Select the Table variable name from the drop-down list.

- Specify the row name or row index to delete.

Note: The index count starts at 0.

Get number of columns action

The Get number of columns action in the Data Table package enables you to retrieve the number of columns from a table.

Settings

Retrieves the number of columns and assigns it to a Number variable. You have the option to select the non-empty columns or include all the columns in the selection.

Get number of rows action

The Get number of rows action in the Data Table package enables you to retrieve the number of rows from a table.

Settings

Retrieves the number of rows and assigns it to a Number variable. You have the option to select the non-empty rows or include all the rows in the selection.

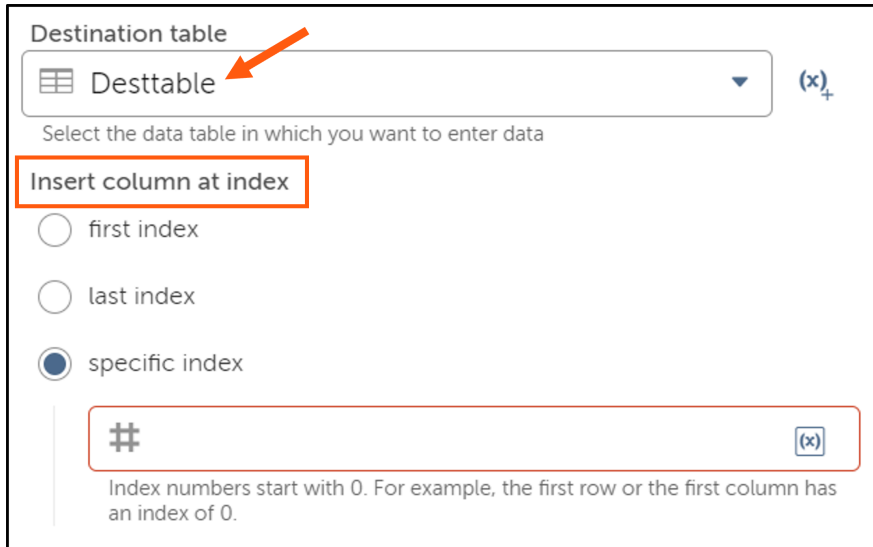

Insert column action

The Insert column action in the Data Table package enables you to insert a column from one table to another table. The Insert column action in the Data Table package enables you to insert a column from one table to another table or insert a custom column of a specified data type to the destination table.

Settings

- In the **Destination table** field, select the destination data table in which you want to enter the data.
- Select where you want to insert the column: **first index**, **last index**, or **specific index**.

Note: If you selected **specific index**, then enter the index number where you want to insert the column.

Destination table

Desttable (x)₊

Select the data table in which you want to enter data

Insert column at index

first index

last index

specific index

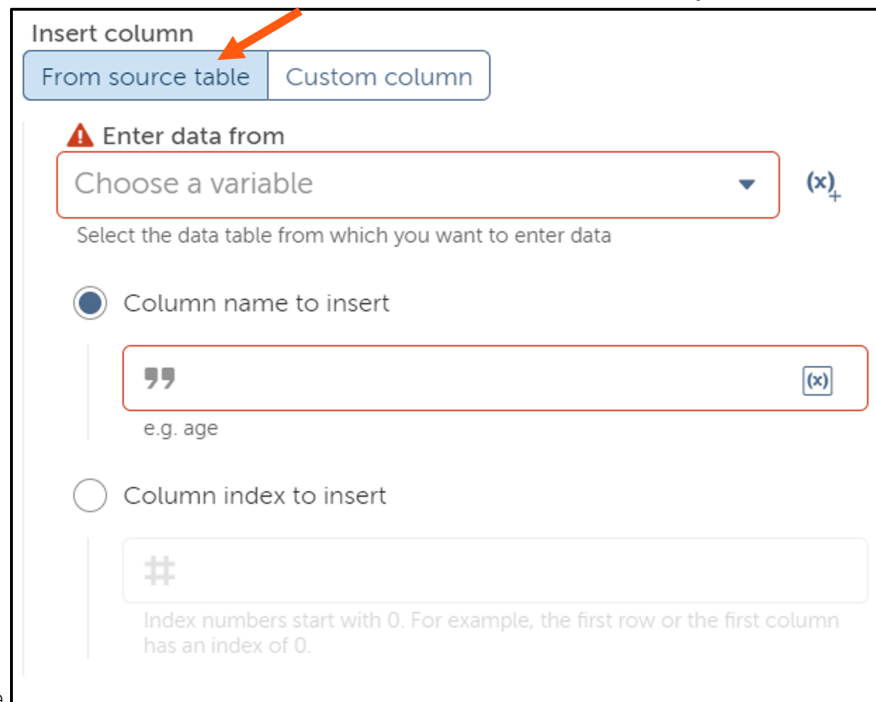

(x)

Index numbers start with 0. For example, the first row or the first column has an index of 0.

- From the **Insert column** option, select one of the following options:
 - **From source table**: Select to enter data from another table to the destination table.
 - **Custom column**: Select to insert an empty column or a column with specified data to the destination table.

Note: You can add only one custom column at a time.

- If you selected the **From source table** option, then perform the following steps:
 - In the **Enter data from** field, select a source table from which you want to enter

Insert column

From source table Custom column

Enter data from

Choose a variable (x)₊

Select the data table from which you want to enter data

Column name to insert

” (x)

e.g. age

Column index to insert

#

Index numbers start with 0. For example, the first row or the first column has an index of 0.

- data
 - Enter the name or index number of the column that you want to insert from the source table.

Note: The index count starts at 0.

- If you have selected the **Custom column** option, then perform the following steps:
 - In the **Column name** field, specify the name of the column that you want to

The screenshot shows the 'Insert column' dialog box with the following fields and values:

- From source table** / **Custom column** (selected)
- Column name (optional)**: Address (with a placeholder 'eg. age')
- Column type**: String
- Default value (optional)**: Bangalore (with a note: 'Default value will be set for all rows in the new column')

- insert.
 - In the **Column type** field, specify the data type of the column that you want to insert.

Note:

- String, Number, Boolean, and Datetime data types are supported.
 - In the **Column type** field, if you select Datetime as the datatype, the default value will be empty. If you run the bot with an empty value in the Datetime variable field, the action uses the current system date and time by default and then inserts that date and time in the Data Table.
-
- In the **Default value** field, specify the value that you want to display in each row of the new column.

See [Example of using Custom column option in Data Table package](#) on page 3135 on how to use the Insert column action.

Insert row action

The **Insert row** action enables you to insert a row into the table.

Settings

- Click the **Data table name** drop-down menu and select a data table.
 - If there is no existing data table, create a new variable of type **Table**.
- Use the **Insert row at index** field to select one of the following positions in the data table for inserting the row:
 - **first position**: to insert a row in the first index.

- **last position**: to insert a row in the last index
- **specific index**: to insert a row in the specific index.

Index refers to the specific row or column in the data table, and starts from 0. For example, index = 0 refers to the first row in the data table.

- Click the **Row record name** drop-down menu and choose an existing record variable to hold the values for the new row that you want to insert.

If there is no existing variable, create a record variable. In the **Create variable** tab, enter the name of the variable and under the **Default value** section, enter the name, value, and the type of value that you want to add to the new row as per the specified index values.

Note: A DataTable variable is created with one row and one column (1x1) by default. This default value is retained along with the row data that you added using the **first position, last position** or **specific index** option.

Consider a scenario where you want to insert a row record named 'March' at the beginning of a data table called 'Sales'.

1. Click the **Data table name** drop-down menu and select Sales.
2. Under the **Insert row at index** field, select **first position**.
3. Click the **Row record name** drop-down menu and select March.
4. Click **Save**.

Using Join action

Use the **Join** action to combine content from two table variables. This action enables you to combine content based on the shared values of a specific column in the tables and store the content into a third Table variable or one of the two source tables.

To join the content from two Table variables, do the following:

1. Double-click or drag **Data table > Join**.
2. Select the first Table variable to use from the **Enter first data table name** list.
3. Enter the name of the column from the first Table variable that contains the data to join.
4. Select the second Table variable to use from the **Enter second data table name** list.
5. Enter the name of the column from the second Table variable that contains the data to join.
6. Select an option to specify the type of join. For more information, see [Join type output examples](#) on page 2373.
 - **inner join**: Returns only the records that have matching values in the selected columns in both tables.
 - **left outer join**: Returns all records from the first table, and the matched records from the second table.
 - **right outer join**: Returns all records from the second table, and the matched records from the first table.
 - **full outer join**: Returns all records when there is a match in either left or right table.
7. In the **Enter name of data table in which to join** field, select the table variable to store the combined values.

Note:

- Starting from Automation 360 v.27 if you are using 4.6.0-20220920-155212 version of the Data Table package, the **Enter name of data table in which to join** field is mandatory and you must specify a third data table in the field to save the result of the Join action.
- When you upgrade from a previous version to Automation 360, and if you have not updated the package version to 4.6.0-20220920-155212, your bots will continue to run as is. In case you have updated both your bots and the package to the latest version, your bots will continue to run successfully if you have selected a table variable to store the output. If the field is empty, then the bot will encounter an error.

Join type output examples

Select a join type option based on your desired output. Use the examples below to guide your selection.

Inner join

Returns only the records that have matching values in the selected columns in both tables.

For example, if you have a table of employees and their departments, and a table of employees and their pay rates, this option will return a table of the employees that exist in both tables, and their departments and pay rates.

Table 1: Employees and Departments

Employee	Department
John	101
Jill	102
Mike	103
Betty	104
Cindy	105

Table 2: Employees and Pay rates

Employee	Pay rate
John	50
Betty	50
Mike	40
Jill	35
Dan	45

Table 3: Employees, Departments, and Pay rates

Employee	Department	Pay rate
John	101	50
Jill	102	35
Mike	103	40
Betty	104	50

Left outer join

Returns all records from the first table, and the matched records from the second table.

Using the example Tables 1 and 2, this option returns the following table:

Table 3: Employees, Departments, and Pay rates

Employee	Department	Pay rate
John	101	50
Jill	102	35
Mike	103	40
Betty	104	50
Cindy	105	

Right outer join

Returns all records from the second table, and the matched records from the first table.

This option returns the following table:

Table 3: Employees, Departments, and Pay rates

Employee	Department	Pay rate
John	101	50
Betty	104	50
Mike	103	40
Jill	102	35
Dan		45

Full outer join

Returns all records when there is a match in either left or right table.

This option returns the following table:

Table 3: Employees, Departments, and Pay rates

Employee	Department	Pay rate
John	101	50
Jill	102	35
Mike	103	40
Betty	104	50
Cindy	105	
Dan		45

Using the Merge action

Use the **Merge** action to combine the contents of two tables when both source tables contain identical column headers. To combine tables that contain different column headers, use the **Join** action.

If one of the tables contains non-identical headers, then the merged table will contain the columns from the first source table with data from the second source table under the identical column headers, followed by the non-identical columns and data from the second source table.

To merge the content, perform these steps:

1. Double-click or drag **Data table > Merge**.
2. Select the first table variable you want to use from the **Enter first data table name** list.
3. Select the second table variable you want to use from the **Enter second data table name** list.
4. Select the table variable that you want to use to store the merged data from the **Enter name of data table in which to merge** list.
5. Click **Save**.

For more information, see [Merge output example](#) on page 2375.

Merge output example

The **Merge** action combines data from two tables with identical column headers, and stores the merged content in a third table or one of the two source tables. These examples demonstrate the output of two tables with identical column headers and the output of two tables with differing column headers.

Output of tables with identical column headers

For example, if you have a table of employees hired in September and a table of employees that were hired in October, this option will return a table of all the employees, with the October hires merged below the September hires.

Table 1: Employees hired in September

Employee	Department	Pay rate
John	101	50

Employee	Department	Pay rate
Jill	102	35

Table 2: Employees hired in October

Employee	Department	Pay rate
Mike	103	40
Betty	104	50

Table 3: All employees

Note: The column headers in the output table are always lowercase.

employee	department	pay rate
John	101	50
Jill	102	35
Mike	103	40
Betty	104	50

Output of tables with differing column headers

In this example, the second table has a different column header. As a result, the third table contains the columns from the first source table with data from the second source table under the identical column headers, followed by the non-identical columns and data from the second source table.

Table 1: Employees hired in September

Employee	Department	Pay rate
John	101	50
Jill	102	35

Table 2: Employees hired in October

Employee	Department	Salary
Mike	103	40
Betty	104	50

Table 3: All employees

employee	department	pay rate	salary
John	101	50	

employee	department	pay rate	salary
Jill	102	35	
Mike	103		40
Betty	104		50

Remove duplicate rows action

The Remove duplicate rows action in the Data Table package enables you to delete any duplicate rows from a table.

Settings

Select the Table variable name from the drop-down list.

Search for a value action

Enables you to search for a specific value in a table and return the row or column numbers in which the entry occurs.

When you search for a value using the **Search for a value** action, it will either return:

- A list of all the positions from the Data table where the search matched
- An empty list if the value is not found.

Settings

- Click the **Enter database name** drop-down and select an existing data table.
If there is no existing data table, click the **Create variable** icon to create a variable.
- Click the **Enter value to search for** drop-down menu to select a variable.
- (Optional) Select the **Match case** check box if the search term is case sensitive.
- (Optional) Click **Assign result to variable** drop-down to select a variable that you want to assign the value that the search returns.

Consider an example where you want to search for an entry called `abc` that is available at the fourth row and third column of a table variable. When you use the action, it returns `3, 2` as output. As the index number for the row and column starts with zero, the values in the output indicates the fourth row and third column.

So it is a x,y structure list where 'x' refers to Row index and 'y' refers to Column index, with base 0 criteria.

Set value of a single cell action

The Set value of a single cell action in the Data Table package enables you to update the value of a specific cell.

Settings

- Select the Table variable name from the drop-down list.
- Enter the row index. For example, to set a value to the first row, enter 0.
- Select whether to specify the column by **Name** or **Index**.
 - If you select to specify by name, enter the column name. Capitalization is not important.
 - If you select to specify by index, enter the column index. For example, to set a value to the first column, enter 0.
- Enter the value to set.

Sort action

The Sort action in the Data Table package enables you to sort the table data by column.

Settings

This action enables you to sort the data by column data format (string, number, datetime, or Boolean).

- Select the Table variable name from the drop-down list.
- Specify the column name or column index to sort by.
- Select the order in which to sort: **ascending order** or **descending order**.

Note: If you built a using this from version 2.0.0-20200624-042148 or earlier, the will be missing when you open the with the default version. You must reinsert the and repopulate the fields.

Using Write to file action

Use the **Write to file** action to write data from a table into file in `.csv` or `.txt` format.

Considerations while using the **Write to file** action:

- Data extracted from a table is written as text into a file that is in `.csv` or `.txt` format.
- Source table typically contains four types of values (string, number, date & boolean). All these values will work with the **Write to file** action.
- Data containing decimals are not truncated unless there is 0 at the end. For example, if the source table has 87.90490, the data is extracted as 87.9049.

1. Double-click or drag **Data table** > **Write to file**.
2. Click the **Data table name** drop-down menu and select the table variable that contains the data that you want to write to a file.

3. Use the **Enter file name** field to specify the location of the file in which you want to write the data.
You can also click the **Browse** button and select the file.
4. Optional: Select the **Create folders/files if it doesn't exist** check box to create the file or folder that you specified in the **Enter file name** field.
5. In the **When writing** field, select one of the following options:
 - **Append to the existing file**: to write the extracted data at the end of the existing file.
 - **Override existing file**: to erase the existing content from the file and write data.
6. Click the **Row delimiter** drop-down menu and select the delimiter to use for rows from the source table.
7. Click the **Column delimiter** drop-down menu and select the delimiter to use for columns from the source table.
8. Optional: Click the **Encoding** drop-down menu to specify the encoding that you want to apply on the file.
The default encoding is set to ANSI
9. Click **Save**.

Database package

Databases support internal operations of an enterprise by storing a variety of data, such as sales transactions, product catalogs, inventories, and customer profiles. Use the Database package to connect to a database, begin a transaction, and manipulate the stored data by retrieving, inserting, updating, deleting, and exporting it to a CSV file.

Before you start

Perform the following actions within the Database package as part of using the set of available actions:

Note: When you use actions such as **Read from**, **Run stored procedure**, or **Export to data table** to retrieve records from a MS SQL Server table which has a bit type column or an Excel column (with **TRUE** or **FALSE** values), then the retrieved data will be referred to 0 and 1, not **TRUE** and **FALSE**.

1. Establish a connection with the database server using the **Connect** action.
See [Using Connect action for database](#) on page 2382.
2. Choose from the following:
 - Use the **Read from** action to retrieve records from the database. See [Using the Read from action](#) on page 2388.
 - If you are automating a task that involves making changes to the database, insert the **Begin database transaction** action, followed by the actions that automate the changes.

This action ensures that all records are updated or deleted in their entirety, and prevents accidental updates or deletions of incomplete data if the bot encounters an error during run time.

3. If you used the **Begin database transaction** action in this session, insert the **End database transaction** to commit the changes.
4. Every set of database actions ends with the **Disconnect** action to terminate the connection to the database server.

Database data types

Data types represent the type of value that can be stored in the database table. The following table provides information about the widely used data types in Automation 360. Note that this is not a comprehensive list.

Data type	Value
Supported data types	Char, Varchar, Nvarchar, Number, Datetime, INT, Float, and Bit
Unsupported data types	<ul style="list-style-type: none"> • Binary data types: Binary, BLOB, CLOB, BFILE, and RAW • Pointer data types: Cursor and Record pointers

Actions in the Database package

The Database package includes the following actions:

Action	Description
Begin database transaction	See Begin database transaction action on page 2381.
End database transaction	See End database transaction action on page 2382.
Connect	See Using Connect action for database on page 2382. The Snowflake database using the ODBC driver is supported.
Disconnect	See Disconnect action on page 2387.
Read from	See Using the Read from action on page 2388. The Snowflake database using the ODBC driver is supported.
Run stored procedure	See Using the Run stored procedure action on page 2389.
Export to data table	See Using the Export to data table action on page 2393. The Snowflake database using the ODBC driver is supported.
Manage stored procedure	See Manage stored procedure action on page 2394.

Action	Description
Insert/Update/Delete	See Insert/Update/Delete action on page 2395.

Related reference

[Loop package](#) on page 2679

Use the Loop package to run a sequence of actions repeatedly for a specific number of times or until a specific condition is met.

[Variables overview](#) on page 2235

Automation 360 offers a variety of variables, each designed to hold specific types of data and is intended for specific use. Use the topics below to learn more about each variable and how to use them.

[Database package updates](#) on page 827

Review the updates in released versions of the Database package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Begin database transaction action

Use the Begin database transaction action in the Database package to starts a database transaction to commit all database actions till the end database transaction.

Settings

- The actions that you insert between the **Begin database transaction** and **End database transaction** actions are treated as a single unit. The bot must run all of the actions successfully in order to update the database. This prevents a partial entry in the event that one of the actions fail.

For example, in double-entry accounting every debit requires the recording of a credit. If a company receives \$5000 of products, the accountant must debit \$5000 to inventory and credit \$5000 to accounts payable.

- Insert the actions that record these entries between the **Begin database transaction** and **End database transaction** actions to ensure that either both entries are recorded or neither is recorded in the database.
- In the **Session name** field, enter the name of the session that you used to connect to the database server in the **Connect** action.

Note: **Begin** and **End database transaction** actions do not support ODBC connectivity.

End database transaction action

Use the End database transaction action Database package to commits all the database operations that were performed with the actions that followed the **Begin database transaction** action.

Settings

- All the database operations that were performed with the actions that followed the **Begin database transaction** action are committed, under the condition that the bot successfully ran those actions.
- In the **Session name** field, enter the name of the session that you used to connect to the database server in the **Connect** action.

Note: **Begin** and **End database transaction** actions do not support ODBC connectivity.

Using Connect action for database

Use the **Connect** action to establish a connection with the database server that you want to use to automate database-related tasks. This action supports Microsoft Access, Microsoft SQL Server, MySQL, Oracle, PostgreSQL Server, and SQLite database servers, as well as the use of CSV, Microsoft Excel, and TXT files as databases.

Important: If your current office installation is any of the following:

- Microsoft 365 Apps for Enterprise
- Office 2016, 2019, or 2021 (Consumer Version 2009 or later)

Then you do not need to install the Microsoft Access Database Engine as an additional component in your system.

However, if you have both Microsoft 365 Apps and the Microsoft Access Database Engine are installed on your system, then you can uninstall the Microsoft Access Database Engine and repair Microsoft 365 Apps.

Microsoft recommends that you do not install the Microsoft Access Database Engine driver separately because both the Microsoft Access Database Engine 2016 and Microsoft 365 Apps use the same major version identifier (16.0). To learn more about the Microsoft Access Database Engine driver installation requirement, see [Unable to use the Access ODBC or OLEDB provider](#)

Note: The SQL Server driver is not dependent on the MS Office installation. Only the Excel Driver version is dependent on the MS Office version.

Specify the details of a database server and associate it with a session name. Use the session name provided in this action in the other actions so that you do not have to provide the details of the database server in those actions.

To establish a connection with a database server, follow these steps:

1. Double-click or drag the **Connect** action from the Database package in the **Actions** palette.
2. Select the **Default** or **User defined** connection option.

When you select **User defined** connection mode and use action **Read from** with encoding ANSI to save the retrieved data in a CSV file, you will see that the retrieved records from the Oracle database display garbled character.

To know more about this issue, see [Fullwidth hyphen is garbled when exporting data to csv by Database: Read from action with encoding ANSI \(A-people login required\)](#)

- If you select the **Default** option, you can directly enter the connection string for any database that supports the JDBC connection strings and a 64-bit driver. To see the list of supported databases, see [Database server support matrix](#) on page 2395.

If you have configured your database and shared repository in the secondary site, use the JDBC connection to connect to the replica database. For example, `jdbc:sqlserver://AGL-ADDRESS:1433;databaseName=DB_NAME;user=username;password=password;applicationInt`

You can establish a connection with the Snowflake database using ODBC drivers. For more information about downloading the ODBC driver, see [Snowflake using ODBC Driver](#)

You can enter the connection string to connect to the database. For example,

`Driver={SnowflakeDSIIDriver};Server={account}.aws.snowflakecomputing.com;Databas`

Use this option to connect to an Excel, CSV, or TXT file. See [Connection Strings by database type](#).

Note: To access any database through ODBC, you must first install a 32-bit ODBC driver on your device.

Parameter: You can use the credential values from the credential locker without exposing the credentials (username or password) in plain text in the connection string. To do so, you must first map the credential in the credential mapper and use the parameter name in the connection string within double curly braces.

For example, if the parameter name is `db_username` and parameter value is chosen from credential value, the connection string

with 3 parameters will be `"Provider=SQLOLEDB.1;Initial`

`Catalog=master;Password={{db_credentials}};Persist Security`

`Info=True;User ID={{db_username}};Data Source={{db_datasource}}"`

To use the password from the credential locker, perform the following steps:

- a) Click **Add parameter**.
- b) Enter the **Parameter name**.
- c) In the **Parameter value**, select **Credential** to use a value available in the credential vault, **Variable** to use a credential variable, or **Insecure string** to manually specify the value you want to use.
- d) Click **Add**.

To ensure a more secure automation, use a Credential Vault variable for the connection string.

Select the **Use ODBC 64-bit driver for connection** option to connect to the database.

Note:

- Ensure that 64-bit access ODBC driver is installed on your system to access any database and perform operations by using database actions.

- The following action does not support the 32-bit or 64-bit ODBC drivers because the listed actions are for database transactions that are carried out after making a connection with the database:
 - Begin database transaction
 - End database transaction
 - Manage stored procedure
- Using Excel as a database, you can process more rows with 64-bit drivers compared to 32-bit ones.

- If you select the **User defined** option, select the database type from the available options and complete the following fields based on the selection:

Database Type	Options
Microsoft SQL Server, PostgreSQL Server	<ul style="list-style-type: none"> Server name: Enter the name of the database server you want to connect to. Database name: Enter the database name. Username: Enter the username you want to use to access the database server. To ensure a secure user name, select a Credential Vault variable. Otherwise, enter a value. Password: Enter the password for the username you have provided. To ensure a secure password, select a Credential Vault variable. Otherwise, enter a value. Instance name: Enter a name for this connection instance. Timeout in seconds (optional) field: Specify the amount of time between 1-9999 you want the system to wait before canceling a bot. <p>The automation will time out and fail if the database connection is not established the specified time. If you do not enter a value in the Timeout in seconds (optional) field, then the default timeout specified in the driver library is used.</p> <hr/> <p>Note: Microsoft SQL Server supports this option only.</p> <hr/> <p>Connect to Microsoft SQL Server with Windows authentication on page 2386</p>
MySQL	Enter the same options as in the Microsoft SQL Server database type. Also, enter the port number. The default port number is 3306.

Database Type	Options
Microsoft Access, SQLite	<p>Select the database file path from:</p> <ul style="list-style-type: none"> • Bots folder • local device • existing file variable
Oracle	<ul style="list-style-type: none"> • Server name (Optional): Enter the name of the Oracle server you want to connect to. • Optional: Select an option to specify the Oracle instance you want to use: <ul style="list-style-type: none"> • System id (SID): Enter the system ID. • Service name: Enter the service name. • TNS Name: Enter the TNS Name available in the <code>tnsnames.ora</code> configuration file. <p>Specify the file path of the <code>tnsnames.ora</code> configuration file, if you have not set the system property with environment variable.</p> <hr/> <p>Note: You can connect to the Oracle Database with the Server name or Oracle instance. If you are connecting using the server name, you must specify the System id (SID) or Service name in the Oracle instance field to identify the Oracle database and its instance. However, if you are connecting using the TNS name, you do not require to enter any value in the Server name field. You should only enter the value of the TNS name and file path.</p> <hr/> • Username: Enter the username you want to use to access the Oracle server. To ensure a secure user name, select a Credential Vault variable. Otherwise, enter a value. • Password: Enter the password for the username you have provided. To ensure a secure password, select a Credential Vault variable. Otherwise, enter a value. • Port: Enter the port number. The default port number is 1521.

Note: If you establish a connection by using a JDBC driver, for Microsoft SQL Server, the Database package already includes the JDBC driver. However, for other database servers,

you must provide the corresponding JDBC driver jar file after downloading it from the appropriate resources.

If you establish a connection by using an ODBC driver, you need not provide a jar file.

3. Select a driver file from the **Bots** folder, the local device, or a file variable.
4. Select any of the following tabs to create a database session:
 - **Local session**: Specify a session name that can be used only in the current bot.
 - **Global session**: Specify a session name that can be used across multiple bots, such as parent bots and child bots.
 - **Variable**: Specify or create a session variable of subtype Database session.
5. Click **Save**.

Choose from the following:

- Use the **Read from** action to retrieve records from the database.
[Using the Read from action](#) on page 2388
- If you are automating a task that involves making changes to the database, insert the **Begin database transaction** action.

This action ensures that all records are updated or deleted in their entirety, and prevents accidental updates or deletions of incomplete data if the bot encounters an error during run time.

[Database package](#) on page 2379

Connect to Microsoft SQL Server with Windows authentication

Configure your device and the Connect action from the Database package to automate connecting to a Microsoft SQL Server with Windows NT authentication.

This task is applicable only for releases prior to Build 9664. Starting from Build 9664, you no longer have to add DLL files manually to connect to the Microsoft SQL Server.

To use Windows NT authentication for connecting to the Microsoft SQL Server, perform the following steps:

1. Download the JDBC driver for Microsoft SQL Server.
[Download the JDBC Driver from Microsoft](#)
2. In the unzipped folder, locate the .dll file in the auth\x64\ file path.
3. If the .dll file has a different name, rename the file to sqljdbc_auth.dll.
4. On the Bot Creator or Bot Runner devices, copy the sqljdbc_auth.dll file to one of the following paths, depending on where you installed the Bot Agent and the option that you selected at the time of installation:

Note: If you are on Build 9664 or later, you do not have to copy the file to the location in which Bot Agent was installed.

- If you installed the Bot Agent at the user level and selected the **Only for me (username)** option, copy to C:\Users\User Name\AppData\Local\Programs\Automation Anywhere\Bot Agent\jre\bin.

- If you installed the Bot Agent at the system level and selected the **Anyone who uses this computer (all users)** option, copy to `C:\Program Files\Automation Anywhere\Bot Agent\jre\bin`.

This enables Windows authentication because the JDBC driver cannot perform the authentication by default.

5. Select the **Default** connection option.
6. Enter the connection string: `jdbc:sqlserver://localhost;databaseName=Test;integratedSecurity=true;`
7. Click **Save**.

Choose from the following:

- Use the **Read from** action to retrieve records from the database.
[Using the Read from action](#) on page 2388
- If you are automating a task that involves making changes to the database, insert the **Begin database transaction** action.

This action ensures that all records are updated or deleted in their entirety, and prevents accidental updates or deletions of incomplete data if the bot encounters an error during run time.

[Database package](#) on page 2379

Disconnect action

Use the Disconnect action in the Database package to disconnect from a database.

Settings

Select any of the following tabs to create a database session:

- **Session name:** Enter or select a local or global session name variable.
- **Variable:** Enter or create a session variable of subtype Database session.

A record set is returned when you run a stored procedure or a query. To use the record set stored in the memory even if the session is disconnected, select **Keep database schema in cache until bot finishes running**. By using this option, you can enable the **Loop** action to iterate the record set by using cached schema after disconnecting from the database.

This capability becomes ineffective in the following conditions:

- The option **Keep database schema in cache until bot finishes running** is selected.
- A new database session is created after the **Disconnect** action.
- The name of the session is same as the previous session.

In this scenario, an error occurs stating a session already exists, and the new database session is not created. To avoid this, you can leave the **Keep database schema in cache until bot finishes running** unchecked.

Note: You cannot delete any files used in a database connection such as `xlsx`, `csv`, or `mdb`. To delete these files, you must not select the **Keep database schema in cache until bot finishes running** check box to disconnect the session without keeping the connection in the cache.

The Snowflake database using the ODBC driver is supported.

Using the Read from action

Use the **Read from** action to retrieve records from the database and save the retrieved data in a CSV file. This action enables you to retrieve up to one million records from the database.

Note: In Automation 360, the bot displays an error when you use **Read from** action to copy the table records using `Select * into tablename from sourcetable`, whereas this functionality is supported in Enterprise 11. If you have such bots created in Enterprise 11 and migrated to Automation 360, we recommend modifying your bots and use **Insert/Update/Delete** action to perform this operation.

To automate the task of selecting and saving a set of records, follow these steps:

1. Enter the name of the session you used to connect to the database server in the **Connect** action.

You do not have to provide the details of the database server here because you have already associated those details with the session name when using the **Connect** action.

2. Enter the SELECT statement to specify the column and table names.

This field supports SQL syntax. For example, `SELECT CustomerName, City FROM Customers`

Note: CTE (Common Table Expression) is supported using `WITH` keyword in the SQL compliant databases such as Oracle and MySQL. For example,

```
WITH customers_in_usa AS (SELECT CustomerName, state FROM customers
WHERE country = 'USA')
SELECT cName FROM customers_in_usa WHERE state = 'LA' ORDER BY
CustomerName
```

3. Enter the maximum number of records to retrieve.
4. Optional: Enter a timeout value.
When the specified time expires, the statement execution stops even if the execution is not completed.
5. Select the **Export data to CSV** option to save the retrieved data.
 - a) Select the file path from the **Bots** folder, the local device, or an existing file variable.
 - b) Select the CSV file encoding to be either **ANSI**, **UNICODE**, or **UTF8**.
 - c) Select whether to export the CSV file with or without the column headers.

With column headers

CustomerName	City
Manny	Pittsburgh
Kate	Los Angeles

CustomerName	City
John	Boston

Without column headers

Manny	Pittsburgh
Kate	Los Angeles
John	Boston

- d) Select this check box if you do not want a CSV file to be created when the SQL query does not return any data.
- e) Specify whether to overwrite the file or append the data to the existing file if a CSV file with the same name exists.

6. Click **Save**.

Using the Run stored procedure action

Stored procedures are a set of SQL statements that are created and stored in the database. These SQL statements might be complex and have to run multiple times. Use the **Run stored procedure** action to execute existing stored procedures.

Note:

- This action does not support Microsoft Access or SQLite database types.
- Starting from Automation 360 v.22 (Build 10526), for stored procedures, the limit of 32 characters for input and output parameters has been removed.

To automate the task of executing a stored procedure, follow these steps:

1. Enter the name of the session you used to connect to the database server in the **Connect** action.

You do not have to provide the details of the database server here because you have already associated those details with the session name when using the **Connect** action.

2. Enter the name of the stored procedure.
3. Optional: Click **Add parameter** to provide an input parameter or configure an output parameter.

Select from the following parameter options:

Option	Steps
Input	<p>Parameter is passed from the bot to the stored procedure.</p> <ul style="list-style-type: none"> • Name: Enter the name of the parameter from the stored procedure. • Value (optional): Enter a value or select a variable. • Type: Select the data type from the following options <ul style="list-style-type: none"> • BIGINT (number) • BINARY (Boolean) • BIT (number) • CHAR (string) • DATE (date time) <p>Supported format yyyy-mm-dd</p> <ul style="list-style-type: none"> • DECIMAL (number) • DOUBLE (number) <p>Default choice for decimal values.</p> <ul style="list-style-type: none"> • FLOAT (number) • INTEGER (number) <p>Uses 4 bytes to store an integer with a value from -2,147,483,648 to 2,147,483,647</p> <ul style="list-style-type: none"> • LONGVARBINARY (Boolean) • LONGVARCHAR (string) • NUMERIC (number) • REAL (number) • SMALLINT (number) <p>Uses 2 bytes to store an integer with a value from -32,768 to 32,767</p> <ul style="list-style-type: none"> • TIME (date time) <p>Supported format hh:mm:ss</p> <ul style="list-style-type: none"> • TIMESTAMP (date time) <p>Supported format yyyy-mm-dd hh:mm:ss.f, where f is fractional seconds</p> <ul style="list-style-type: none"> • TINYINT (number) <p>Uses 1 byte to store an integer with a value from 0 to 255</p> <ul style="list-style-type: none"> • VARBINARY (Boolean) • VARCHAR (string) <p>For example, if running the example function from the Manage stored procedure action, configure the following two input parameters and values for the <code>sum_of_two</code> function to add:</p> <ul style="list-style-type: none"> • Parameter 1: num1, 5, TINYINT • Parameter 2: num2, 10, TINYINT

Option	Steps
Output	<p>Parameter is passed from the stored procedure to the bot.</p> <ul style="list-style-type: none"> • Name: Enter the name of the parameter from the stored procedure. • Type: Select the data type from the following options <ul style="list-style-type: none"> • BIGINT (number) • BINARY (Boolean) • BIT (number) • CHAR (string) • DATE (date time) <p>Supported format yyyy-mm-dd</p> • DECIMAL (number) • DOUBLE (number) <p>Default choice for decimal values.</p> • FLOAT (number) • INTEGER (number) <p>Uses 4 bytes to store an integer with a value from -2,147,483,648 to 2,147,483,647</p> • LONGVARBINARY (Boolean) • LONGVARCHAR (string) • NUMERIC (number) • REAL (number) • SMALLINT (number) <p>Uses 2 bytes to store an integer with a value from -32,768 to 32,767</p> • TIME (date time) <p>Supported format hh:mm:ss</p> • TIMESTAMP (date time) <p>Supported format yyyy-mm-dd hh:mm:ss.f, where f is fractional seconds</p> • TINYINT (number) <p>Uses 1 byte to store an integer with a value from 0 to 255</p> • VARBINARY (Boolean) • VARCHAR (string) <p>When the bot runs, the action converts the database data type to an Automation 360-supported data type.</p> <p>For example, if running the example <code>sum_of_two</code> function from the Manage stored procedure action, configure the output parameter: <code>sum, TINYINT</code>.</p>

Option	Steps
InputOutput	<p>Parameter can be used for both input and output.</p> <ul style="list-style-type: none"> • Name: Enter the name of the parameter from the stored procedure. • Value (optional): Enter a value or select a variable. • Type: Select the data type from the following options <ul style="list-style-type: none"> • BIGINT (number) • BINARY (Boolean) • BIT (number) • CHAR (string) • DATE (date time) <p>Supported format yyyy-mm-dd</p> <ul style="list-style-type: none"> • DECIMAL (number) • DOUBLE (number) <p>Default choice for decimal values.</p> <ul style="list-style-type: none"> • FLOAT (number) • INTEGER (number) <p>Uses 4 bytes to store an integer with a value from -2,147,483,648 to 2,147,483,647</p> <ul style="list-style-type: none"> • LONGVARBINARY (Boolean) • LONGVARCHAR (string) • NUMERIC (number) • REAL (number) • SMALLINT (number) <p>Uses 2 bytes to store an integer with a value from -32,768 to 32,767</p> <ul style="list-style-type: none"> • TIME (date time) <p>Supported format hh:mm:ss</p> <ul style="list-style-type: none"> • TIMESTAMP (date time) <p>Supported format yyyy-mm-dd hh:mm:ss.f, where f is fractional seconds</p> <ul style="list-style-type: none"> • TINYINT (number) <p>Uses 1 byte to store an integer with a value from 0 to 255</p> <ul style="list-style-type: none"> • VARBINARY (Boolean) • VARCHAR (string)

4. Enter the maximum number of records to retrieve.
You can limit the results of the execution.
5. Optional: Enter a timeout value.
When the specified time expires, the statement execution stops even if the execution is not completed.
6. Optional: Select the **Export data to CSV** option to save the retrieved data.

Note: The **Export data to CSV** option does not support Oracle Database or PostgreSQL Server database types. Use output parameters to retrieve values.

- a) Select the file path from the **Bots** folder, the local device, or an existing file variable.
- b) Select the CSV file encoding to be either **ANSI, UNICODE, or UTF8**.
- c) Select whether to export the CSV file with or without the column headers.

With column headers

CustomerName	City
Manny	Pittsburgh
Kate	Los Angeles
John	Boston

Without column headers

Manny	Pittsburgh
Kate	Los Angeles
John	Boston

- d) Specify whether to overwrite the file or append the data to the existing file if a CSV file with the same name exists.
7. Optional: Select a dictionary variable to hold the output if the stored procedure returns a value.
- Each output parameter name is a dictionary key which holds the corresponding parameter value.
- For example, if you assign the `sum_of_two` function output to `$Output$`, when the bot calls `$Output {sum} $`, the variable returns 15.

Note: If you do not know the output parameter name, use the default key `Output` appended by the parameter index number.

8. Click **Save**.

Using the Export to data table action

Use the **Export to data table** action to retrieve records from the database and store the retrieved data in a table variable.

To automate the task of selecting and saving a set of records, follow these steps:

1. Enter the name of the session you used to connect to the database server in the **Connect** action.

You do not have to provide the details of the database server here because you have already associated those details with the session name when using the **Connect** action.

2. Enter the SELECT statement to specify the column and table names.

This field supports SQL syntax. For example, `SELECT CustomerName, City FROM Customers`

Note: CTE (Common Table Expression) is supported using `WITH` keyword in the SQL compliant databases. For example, `WITH customers_in_usa AS (SELECT CustomerName, state FROM customers WHERE country = 'USA') SELECT cName FROM customers_in_usa WHERE state = 'LA' ORDER BY CustomerName`

3. Enter the maximum number of records to retrieve.
 4. Optional: Enter a timeout value.
When the specified time expires, the statement execution stops even if the execution is not completed.
 5. In the **Assign to** option, select the table variable to store the retrieved data.
-

Note:

If the data table has some existing values, the new table overrides the existing data table. For example, if you use **Export to table** action twice in a bot with different select queries, the last used **Export to table** action will override the existing table.

6. Click **Save**.

Manage stored procedure action

Use the Manage stored procedure action in the Database package to create, update, and delete a stored procedure within the specified database. A stored procedure is SQL code saved to the database, enabling you to run it repeatedly.

Settings

- In the **Session name** field, enter the name of the session that you used to connect to the database server in the **Connect** action.
 - In the **Enter full command** field, enter the command to create, update, or delete the stored procedure. You can specify input and output parameters for the command; you provide values or variables holding the values in the **Run stored procedure** action.
-

Note: Declare a delimiter and use it to close the SQL statement.

MySQL example: In this example, the bot checks if there is a procedure in the database named `sum_of_two`. If not, the bot creates a procedure that accepts two input parameters (`num1` and `num2`), adds them together, and produces the sum as the output parameter:

```
DROP PROCEDURE IF EXISTS sum_of_two;
DELIMITER $$
CREATE PROCEDURE sum_of_two(IN num1 INT, IN num2 INT, OUT sum
INT)
BEGIN
SET sum := num1 + num2;
END
$$
```

- In the **Timeout for the query in seconds** field, specify the time within which the statement execution should stop, even if the execution is not completed.

Insert/Update/Delete action

Use the Insert/Update/Delete action in the Database package to execute an INSERT, UPDATE, or DELETE statement from the database.

Settings

- In the **Session name** field, enter the name of the session that you used to connect to the database server in the **Connect** action.
- In the **Statement** field, enter the SQL statement to insert, update, or delete the records.

- Use an INSERT statement to create new records in a table:

```
INSERT INTO table_name (column1, column2, column3, ...)
VALUES (value1, value2, value3, ...)
```

- Use an UPDATE statement to modify a record:

```
UPDATE table_name
SET column1 = value1, column2 = value2, ...
WHERE condition
```

- Use a DELETE statement to remove a record:

```
DELETE FROM table_name WHERE condition
Example: DELETE FROM Persons WHERE LastName='Smith'
```

- In the **Timeout for the query in seconds** field, specify the time within which the statement execution should stop, even if the execution is not completed.

If you do not enter a value in the **Timeout for the query in seconds** field, then the default timeout specified in the driver library is used.

Database server support matrix

Review the list of databases supported in Automation 360 and their JDBC and ODBC connectivity.

JDBC connectivity

The following table lists the supported database servers with JDBC connectivity.

Datab: MS action SQL server	MS access	Postgr My Server SQL	Excel	Text	CSV	Snowf DB2	Oracle AWS RDS	Micro: MariaDB Azure

Datetime package

A datetime value consists of a date, time, and time zone. Automation Workspace stores datetime values in a Datetime variable. The **Datetime** package contains actions that enable you to perform various operations on datetime values. You can use these actions to manipulate and compare values in the Datetime variables.

Actions in the Datetime package

You can enter either a **String** or a **Global** variable for any of the actions in the Datetime package. The actions then assign the output to a variable.

The actions in the **Datetime** package accept a variable as an input and assign the output to a variable. These actions enable you to compare two Datetime values, add to or subtract from a Datetime value, and convert a Datetime value to a string value.

The **Datetime** package includes the following actions:

Action	Description
Add	See Using the Add action on page 2398.
Assign	See Using the Assign action on page 2399.

Action	Description
Is after	See Is after action in Datetime on page 2400.
Is before	See Is before action in Datetime on page 2400.
Is equal	See Is equal action in Datetime on page 2401.
Subtract	See Using the Subtract action on page 2401.
To string	See Using the To string action on page 2402.

[Datetime formats](#) on page 2402

Specify a custom format when you convert a datetime value to a string value by using the predefined formats available in Automation Workspace.

[Datetime package updates](#) on page 829

Review the updates in released versions of the Datetime package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using the Add action

Use the **Add** action to increase the value in the Datetime variable by a specified time value and unit. For example, you can use this action to increase the Datetime variable value by three hours or by three days.

To add a value to a Datetime variable, do the following:

1. Double-click or drag the **Add** action from the **Datetime** node in the **Actions** palette.
2. Select an option from the **Source date and time variable** list to specify the variable that contains the value to which you want to add the time unit.
3. Enter the value you want to add in the **Time value to add** field.
4. Select an option from the **Time unit to add** list to specify the time unit you want to add.

Choose from the following time unit options:

- Milliseconds
- Seconds
- Minutes
- Hours
- Days
- Weeks
- Months
- Years

Note: This action accounts for leap years. For example, if the action adds 28 days to February 1, 2020, the action output is February 29, 2020. Whereas, if the action adds 28 days to February 1, 2019, the action output is March 1, 2019.

5. Select the Datetime variable from the **Assign the output to a variable** list to specify the variable to which you want to assign the output.
6. Click **Save**.

To see the output value, convert the value in the Datetime variable to a String variable, then print the value with the **Message Box** action. For more information, see [Using the To string action](#) on page 2402 and [Using the Message box action](#) on page 2691.

Using the Assign action

Use the **Assign** action to assign a String variable with a selected datetime format, assign a datetime value manually, or assign an existing Datetime variable into a Datetime variable.

To assign values to a Datetime variable, perform the following steps:

1. Double-click or drag the **To string** action from the **Datetime** node in the **Actions** palette.
2. Select either the **Enter the date time** or **Variable** option.
 - If you selected the **Enter the date time** option, perform the following steps:
 - a) Enter the date time values or select a String variable.

Note: To enter multiple variables, separate them with single quotation marks. For example, to input the variables date1 and time1, enter the following: 'date1"time1'

 - b) Select the date time format.

Choose from the prebuilt formats or provide a custom format. For more information about the prebuilt formats, see [Datetime formats](#) on page 2402.
 - If you selected the **Variable** option, choose either the **Datetime** option or the **Variable** option.
 - Use the **Datetime** option if you want to select the date, time, and timezone manually.
 - Use the **Variable** option if you want to select the Datetime variable or other variables that can have Datetime as a subtype, such as the Dictionary, Record, and list variables.
3. Select the variable to use to store the output from the **Destination Datetime variable** list.
4. Click **Save**.

Is after action in Datetime

The **Is after** action in the Datetime package compares two Datetime variables and verifies if the value of the source variable is after the value available in the comparison variable, and stores the output to a Boolean variable.

Settings

- From the Source date and time variable section, select either the **Datetime** or **Variable** option. Use the **Datetime** option to enter the date and time. Use the **Variable** option to select the global value.
- Select the source variable from the **Source date and time variable** list, and select the variable you want to compare with from the **Date and time variable to be compared to** list.
- Select the Datetime variable from the **Assign the output to a variable** list to specify the variable you want to use to assign the output.

For example, if the value in the source variable is after the value in the comparison variable, the system stores `True` as the output in the Boolean variable. If the value in the source variable is not after the value in the comparison variable, the system stores `False` as the output in the Boolean variable.

Is before action in Datetime

The **Is before** action in the Datetime package compares two Datetime variables and verifies if the value of source variable is before the value available in the comparison variable, and stores the output to a Boolean variable.

Settings

- Select the source variable from the **Source date and time variable** list, and select the variable you want to compare with from the **Date and time variable to be compared to** list.
- Select the Datetime variable from the **Assign the output to a variable** list to specify the variable you want to use to assign the output.

For example, if the value in the source variable is before the value in the comparison variable, the system stores `True` as the output in the Boolean variable. If the value in the source variable is not before the value in the comparison variable, the system stores `False` as the output in the Boolean variable.

Is equal action in Datetime

The **Is equal** action in the Datetime package compares two Datetime variables and verifies if the value of the source variable is equal to the value available in the comparison variable, and stores the output to a Boolean variable.

Settings

- Select the source variable from the **Source date and time variable** list, and select the variable you want to compare with from the **Date and time variable to be compared to** list.
- Select the Datetime variable from the **Assign the output to a variable** list to specify the variable you want to use to assign the output.

For example, if the value in the source variable is equal to the value in the comparison variable, the system stores `True` as the output in the Boolean variable. If the value in the source variable is not equal to the value in the comparison variable, the system stores `False` as the output in the Boolean variable.

Using the Subtract action

Use the **Subtract** action to decrease the value in the Datetime variable by a specified time value and unit. For example, you can use this action to decrease the Datetime variable value by three hours or by three days.

To subtract a value from a Datetime variable, do the following:

1. Double-click or drag the **Subtract** action from the **Datetime** node in the **Actions** palette.
2. Select an option from the **Source date and time variable** list to specify the variable that contains the value from which you want to subtract the time unit.
3. Enter the value you want to subtract in the **Time value to subtract** field.
4. Select an option from the **Time unit to subtract** list to specify the time unit you want to subtract.

Choose from the following time unit options:

- Milliseconds
- Seconds
- Minutes
- Hours
- Days
- Weeks
- Months
- Years

Note: This action accounts for leap years. For example, if the action subtracts 31 days from March 31, 2020, the action output is February 29, 2020. Whereas, if the action subtracts 31 days from March 31, 2019, the action output is February 28, 2019.

5. Select the Datetime variable from the **Assign the output to a variable** list to specify the variable to which you want to assign the output.
6. Click **Save**.

To see the output value, convert the value in the Datetime variable to a String variable, then print the value with the **Message Box** action. For more information, see [Using the To string action](#) on page 2402 and [Using the Message box action](#) on page 2691.

Using the To string action

Use the **To string** action to convert a datetime value to a string value. This action enables you to select a predefined format or specify a custom format for the output value.

You can select a predefined format for datetime or provide a custom format based on your requirements. See [Datetime formats](#) on page 2402.

To convert a datetime value to string, do the following:

1. Double-click or drag the **To string** action from the **Datetime** node in the **Actions** palette.
2. Select an option from the **Source date and time variable** list to specify the variable that contains the datetime value that you want to convert to a string value.
3. Select an option from the **Formats** list to specify the predefined format in which you want to store the string value.
4. Select the **Custom format** to specify a custom format based on your requirement.
[Datetime formats](#) on page 2402
5. Select the string variable that you want to use to store the converted value from the **Assign the output to a variable** list.
6. Click **Save**.

Datetime formats

Specify a custom format when you convert a datetime value to a string value by using the predefined formats available in Automation Workspace.

The **To string** action enables you to convert a datetime value to a string value. This action also enables you to select a predefined datetime format or specify a custom format.

Predefined datetime format

When you convert a datetime value to a string value, the predefined datetime formats are available in the **Formats** list. The following predefined datetime formats are available:

- **BASIC_ISO_DATE**: Converts the datetime value to a `yyyymmdd+offset` value string value.
- **ISO_LOCAL_DATE**: Converts the datetime value to a `yyyy-mm-dd` string value.
- **ISO_OFFSET_DATE**: Converts the datetime value to a `yyyy-mm-dd+offset` value string value. The offset value indicates the difference between the local time and UTC in hours and minutes.
- **ISO_DATE**: Converts the datetime value to a `yyyy-mm-dd+offset` value or `yyyy-mm-dd` string value. The system adds an offset value if it is available.
- **ISO_LOCAL_TIME**: Converts the datetime value to a `hh:mm:ss.SSS` string value.
- **ISO_OFFSET_TIME**: Converts the datetime value to a `hh:mm:ss.SSS+offset` value string value. The offset value indicates the difference between the local time and UTC in hours and minutes.

- **ISO_TIME**: Converts the datetime value to a `hh:mm:ss.SSS`, or `hh:mm:ss.SSS+offset value` string value. The offset value indicates the difference between the local time and UTC in hours and minutes.
- **ISO_LOCAL_DATE_TIME**: Converts the datetime value to a `yyyy-mm-ddThh:mm:ss.SSS` string value.
- **ISO_OFFSET_DATE_TIME**: Converts the datetime value to a `yyyy-mm-ddThh:mm:ss.SSS+offset value` string value. The offset value indicates the difference between the local time and UTC in hours and minutes.
- **ISO_ZONED_DATE_TIME**: Converts the datetime value to a `yyyy-mm-ddThh:mm:ss.SSS+offset value[zone id]` string value. The offset value indicates the difference between the local time and UTC in hours and minutes. The 'zone id' in the format represents the time zone.
- **ISO_DATE_TIME**: Converts the datetime value to a `yyyy-mm-ddThh:mm:ss.SSS`, `yyyy-mm-ddThh:mm:ss.SSS+offset value`, or `yyyy-mm-ddThh:mm:ss.SSS+offset value[zone id]` string value.
- **ISO_ORDINAL_DATE**: Converts the datetime value to a `yyyy-[day of the year]`, or `yyyy-[day of the year]+offset value` string value. For example, if the datetime value is 'January 25, 2018', it is formatted as '2018-25' where '25' indicates the day of the year.
- **ISO_WEEK_DATE**: Converts the datetime value to a `yyyy-[week of the year]-[day of the week]`, or `yyyy-[week of the year]-[day of the week]+offset value` string value. For example, if the datetime value is 'January 25, 2018', it is formatted as '2018-W4-4' where 'W4' indicates that it is the fourth week of the year and '4' indicates the day of that week.
- **ISO_INSTANT**: Converts the datetime value to a `yyyy-mm-ddThh:mm:ss.SSSZ` string value.
- **RFC_1123_DATE_TIME**: Converts the datetime value to a `[day of the week], [day of the month] [month in 'MMM' format] [year in 'YYYY' format] hh:mm:ss`, or `[day of the week], [day of the month] [month in 'MMM' format] [year in 'YYYY' format] hh:mm:ss+offset value` string value. For example, if the datetime value is '2018-01-25 10:15', it is formatted as 'Thu, 25 December 2018 10:15:00GMT'. The 'GMT' indicates that there is no offset available.

Custom datetime format

Use predefined conventions to specify a custom datetime format. The following conventions are available:

Note: All predefined conventions that are used to specify a custom datetime format are case-sensitive.

- 'y' and 'Y': Specify a year as 'yy' or 'yyyy' and specify the year of the week as 'YY' respectively.
-

Note: The 'yy' and 'YY' provide the same result, however the result differs if you use a datetime format that includes the last week or the first week of a calendar year.

For example, when you use a datetime format as 12/26/22 (2022/12/26), then perform actions to delete the files from the previous year, the datetime format 'yy' provides correct result (12/26/21) and the files from the year 2021 are deleted. If you use the datetime format 'YY' (indicating the year of the week in which the specific day appears), then files from the year 2022 will be deleted because the day 12/26/21 falls during the last week of 2021 and also during the first week of 2022.

We recommend that you use the datetime format 'yy' when you want to consider the calendar year only and not a specific week of that calendar year.

- 'M': Specify a month as 'M', 'MM', 'MMM' (abbreviated name of the month, for example, Jan, Feb), or 'MMMM' (full name of the month, for example, January, February).

Note: The 'MMM' and 'MMMM' datetime formats work depending on the operating system on which the Bot Agent runs and your location setting.

- 'd': Specify a day as 'd' or 'dd'.
- 'D': Specify a day in a year as 'D' or 'DD'.
- 'E': Specify day of the week as 'EEE' (Sun-Sat) or 'EEEE' (Sunday-Saturday).

Note: The 'EEE' and 'EEEE' datetime formats work depending on the operating system on which the Bot Agent runs and your location setting.

- 'h' or 'H': Specify an hour as 'hh' or 'HH'.

Note: HH is a 24-hour time format, and hh is a 12-hour time format with AM or PM. When you use the hh format, add a at the end of the datetime format. For example, if the system locale language is English, the input will be 2018-12-25 10:50:55.999 AM and the format will be yyyy-MM-dd hh:mm:ss.SSS a where a indicates AM or PM. However, on computers that use operating systems in languages other than English, use AM or PM marker accordingly. For example, on a Japanese language operating system, the input must have AM or PM marker in Japanese, such as 2018-12-25 10:50:55.999 午前, where 午前 means AM in Japanese, and the format must be yyyy-MM-dd hh:mm:ss.SSS a.

- 'a': Specify an AM/PM marker for the 12-hour time format
- 'm': Specify a minute in an hour as 'mm'.
- 's': Specify a second in a minute as 'ss'.
- 'S': Specify a millisecond as 'SSS'.
- 'z': Specify a timezone, such as 'Pacific Standard Time' and 'Indian Standard Time'.
- 'Z': Specify an offset time for a timezone, such as '+0550' for 'Indian Standard Time'.

Important: On computers where the display language is set to Simplified Chinese or Traditional Chinese, when you use the dd-MMM-yyyy custom datetime format to convert a datetime value to a string value, the output might show incorrectly.

You can use the preceding convention to specify the custom format that you want to use for converting a datetime value. Some examples that use the preceding convention are as follows:

Format	Sample output
yyyy-MM-dd	2018-09-30
yyyy-M-d	2020-9-8

Delay package

Use the `Delay` package to add a timed delay to the logic.

You can use timed delay to add the amount of time a bot waits before moving to the next task. You can specify the amount of time in milliseconds or seconds.

Note: You can specify a maximum time delay of 9999999 milliseconds or seconds.

Example: If we give a timed delay of 5 seconds, the bot will wait for 5 seconds and then execute the action following the delay.

The `Delay` package includes the following action:

Action	Description
Delay	See Delay action in Delay on page 2405.

Related reference

[Delay package updates](#) on page 830

Review the updates in released versions of the `Delay` package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Delay action in Delay

Use the **Delay** action in the `Delay` package to add a timed delay.

Settings

- Select the **Delay type** as **Regular** or **Random**.

- Select the **Regular** option to delay the operation for a fixed period of time.
- If you select **Random**, specify the time range in the **From** and **To** fields for the system to select a random delay within the specified range.

You can add **Random** delay with different waiting time for each bot run at a given command level without having to change the bot.

Example: Use **Random** delay when running bots simultaneously on several machines through a workload management queue before executing a database or recorder, or the FTP action. This would reduce the number of concurrent requests made to a database or the FTP server and the performance of the systems will not be adversely impacted.

- Select the **Time unit** in **Milliseconds** or **Seconds**.

Dictionary package

The **Dictionary** package contains actions that enable you to do various operations on dictionary-type values.

Dictionary data type

A dictionary is a collection of key-value pairs, in which each key has a value. It is similar to an entry in a dictionary, where each word has a corresponding definition or explanation. The key is similar to the word, and the definition or explanation is similar to its value. The properties of dictionary entries are as follows:

- Keys are unique within each dictionary variable. If you try to duplicate a key, you will overwrite its value.
- Key names cannot be changed.
- Keys are case-sensitive.
- Keys can contain leading and trailing whitespaces.

Each key-value pair in a dictionary is separated by a colon. The key-value pairs are separated from each other by commas. An example of a dictionary is as follows:

```
invoice = {'CustomerID': 9876, 'Location': 'XYZ', 'Amount': 12,34,567}
```

In the example, 'CustomerID', 'Location', and 'Amount' are keys, and the corresponding value assigned to each key is separated by a colon.

Working with variables of dictionary data type

A dictionary variable can hold values of boolean, number, or string data subtype. When initializing a dictionary variable, you can select the **Any** data subtype in order to hold any of the three data subtypes. You can manually enter values by creating a new variable or selecting an existing one from the Variables menu, and then clicking **Add**.

Use a dictionary variable to hold [email](#) or [PDF](#) properties.

Note: When you use either the dictionary variable or the **Get** action from the Dictionary package to verify whether a key exists in a dictionary variable and retrieve its corresponding value, different output displays if the key does not exist:

- The dictionary variable retrieves a null value.
- The **Get** action retrieves a blank value.

Actions in the Dictionary package

The following actions are available:

Action	Description
Assign	See Assign action in Dictionary on page 2407.
Get	See Get action in Dictionary on page 2409.
Put	See Put action in Dictionary on page 2410.
Remove	See Remove action in Dictionary on page 2410.
Size	See Size action in Dictionary on page 2410.

[Dictionary package updates](#) on page 831

Review the updates in released versions of the Dictionary package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Assign action in Dictionary

You can use the **Assign** action in the Dictionary package to assign the value of a source dictionary to the destination dictionary variable.

Example of assigning a source dictionary value

This example shows you how to create a bot that assigns the source dictionary value to the destination dictionary variable.

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name: `Dictionary_Assign`.
 - d) Click **Create and Edit**.
2. Create the user-defined variables using the **Create variable (+)** icon at the top of the **Variables** menu.

- Create two variables of **Dictionary** type:
 - Source dictionary variables: AppraisalData_FY22
 - Destination dictionary variable: AppraisalData_FY23
- Enter the following key-pair values in the source and destination dictionary variables.

AppraisalData_FY22 (Source)

Key	Value
Name	Bob, John, Sarah
Age	52, 26, 42
Job title	Sr. Developer, Technical Writer, HR
Email ID	bob.jones@abc.com, john@abc.com, sarah@abc.com
Phone number	752000000, 753000000, 754000000
CTC	\$160,000, \$110,000, \$100,000
Bonus component	Sr. Developer: 15%, Technical Writer: 15%, HR: 15%
Employment type	Sr. Developer: Permanent, Technical Writer: Contractor, HR: Permanent

AppraisalData_FY23 (Destination)

Key	Value
Name	Bob, John, Sarah
Age	52, 26, 42
Job title	Sr. Developer, Technical Writer, HR
Email ID	bob.jones@abc.com, john@abc.com, sarah@abc.com
Phone number	752000000, 753000000, 754000000
CTC	\$170,000, \$120,000, \$110,000

3. To assign the value of the source dictionary to the destination dictionary variable, double-click or drag the **Dictionary > Assign** action.
 - a) Select the source dictionary variable from the drop-down list or create and enter AppraisalData_FY22 in the **Select the source dictionary variable** field.
 - b) To hold the output, select a variable or create and enter AppraisalData_FY23 in the **Select the destination dictionary variable** field.

Note: If both (source and destination) dictionary variables contain the same keys, the destination dictionary variable will be overwritten by the value of the source dictionary variable.

4. To print the value of the destination variable (AppraisalData_FY23), double-click or drag the **Message box** action. Enter the following values in the **Enter the message to display** field:
 - \$AppraisalData_FY23{"Job tile"}\$
 - \$AppraisalData_FY23{"CTC"}\$
 - \$AppraisalData_FY23{"Bonus component"}\$
 - \$AppraisalData_FY23{"Employment type"}\$
5. Click **Save** and then **Run**.

The output is displayed as:

The output shows that the key and its values (Bonus and Employment type) in the source variable (AppraisalData_FY22) are assigned to the destination variable (AppraisalData_FY23). Additionally, the source and destination variables contain the same keys for CTC. As a result, the value in the destination dictionary variable is overwritten by the value of the source dictionary variable.

Get action in Dictionary

Use the **Get** action in the Dictionary package to verify if a key exists in a dictionary variable and return the corresponding value.

Settings

- Select the dictionary variable from the drop-down list.
- Enter the key name.
- Select a dictionary variable or create one to hold the output.

Put action in Dictionary

Use the **Put** action in the Dictionary package to assign a value to a key in the dictionary. If the key is already associated with a value, the value can be updated.

Settings

- Select the dictionary variable from the drop-down list.
- Enter the key name.
- Assign a value to the key.

You can choose the **Static value** tab to add the values manually or the **Variable** tab to add the existing variables.

Note: If you choose the Static value option, ensure that the data type of static value matches the subtype of the dictionary variable. Otherwise, you might encounter type cast errors when you use the dictionary variables.

- Select the variable to hold the previous value.

Remove action in Dictionary

Use the **Remove** action in the Dictionary package to remove a value from the specified key. The removed value is assigned to a variable selected from the **Assign removed item to variable** list.

Settings

- Select the dictionary variable from the drop-down list.
- Enter the key name.
- Select the variable to hold the removed value.

Size action in Dictionary

Use the **Size** action in the Dictionary package to retrieve the number of entries in the dictionary.

Settings

Retrieves the number of entries in the dictionary specified in the **Dictionary variable** field and assigns the output to a number variable selected from the **Assign the output to variable** list.

DLL package

A dynamic-link library (DLL) file contains a shared library of functions that can be used by Windows programs. The **DLL** package uses a `.dll` file as reference and calls functions from the bot.

Before you start

Perform the following actions within the **DLL** package as part of using the set of available actions:

Note:

- If you create bots using custom DLL, and the custom DLL has a dependency on the Apache log4net library, then we recommend using:
 - log4net version 2.0.11 or later in the custom DLL.
 - Update the Bot Agent (version 21.210 or later) even if the Bot Agent update is optional.
 - Only the DLLs built using the Microsoft .NET Framework are supported.
 - The Run DLL package is compatible with the following versions of Microsoft .NET: 4.6, 4.7, and 4.8.
 - When you create a bot and use the local session with loop, ensure that you use the close session action in the bot. If you do not use the close session command, then the local session will open `AutomationAnywhere.ManagedDLLWrapper.exe` with each iteration of the loop. As a result, you will run out of memory space and the bot will fail.
-

Important: If you use different versions of the DLL package in a parent bot and a child bot, the capability to share a session across bots is currently not supported. To share a session across parent and child bots, ensure that you use the same version of the package in both the parent and child bots.

1. Use the **Open** action to specify the location of the `.dll` file you want to use and session name. Use this same session name for the other actions. The `.dll` referenced is automatically added as a bot dependency.
2. Use the **Run function** action to run a function from the `.dll` and save its output value as a variable.
3. After running the required functions, close the `.dll` reference. It is important to close the `.dll` reference to free the memory of the operating system.

Windows and appropriate versions of Microsoft .NET Framework are available on the devices running the DLLs.

To review the bot launcher logs, navigate to `C:\ProgramData\AutomationAnywhere\BotRunner\Logs\<current month>\Bot_Launcher-<today's date>.log.zip`. Each zipped folder contains a file with data on the code execution, which is useful for debugging.

Note: If the `.dll` file uses .NET functions or classes from another `.dll` file, you must add the second `.dll` file as a manual dependency of the bot.

[Bot dependencies](#) on page 2268

When you import multiple DLLs that have one main DLL and other DLLs are referenced from it, ensure you have all the DLLs in one folder. Also, the referenced DLLs must be called using a session name that is different from the name used in the main DLL. Your bot execution will fail if the same session name is used in both the main and the referenced DLLs.

Actions in the DLL package

The **DLL** package includes the following actions:

Action	Description
Close	See Close action on page 2416
Open	See Open action on page 2417
Run function (Legacy)	<p>See Using the Run function action.</p> <hr/> <p>Note:</p> <ul style="list-style-type: none"> The Run function (Legacy) action is no longer available in the Run DLL package. We recommend that you use the Run Function action from the Run DLL package because this action is an improved version of the Run function (Legacy) action. <p>Note that existing bots that use the Run function (Legacy) will continue to run successfully without any issues.</p> <ul style="list-style-type: none"> This action is called Run function (Legacy) starting from Enterprise A2019.16. The action is called Run function in Enterprise A2019.15 and previous releases. <hr/>
Run function	See Using the Run function action on page 2419.

Supported data types in DLL functions

The following table list the variables and data types that you can use as an input or output parameter in DLL functions.

Note: The **Run function** and **Run function (Legacy)** actions do not support any user-defined data types in the **Parameter to the function** or **Assign output to variable** field.

Variable type as input or output parameters	Supported data types in .NET
String	<ul style="list-style-type: none">• Char• Byte• String• string• SByte
Number	<ul style="list-style-type: none">• UInt16• Int16• UInt32• Int32• UInt64• Int64• Int• Single• Decimal• Float• Double
Boolean	<ul style="list-style-type: none">• Boolean• bool
Datetime	<ul style="list-style-type: none">• Datetime

Variable type as input or output parameters	Supported data types in .NET
List	<ul style="list-style-type: none"> • UInt16[] • Int16[] • Int32[] • Int64[] • Int[] • Char[] • Single[] • Decimal[] • Float[] • Double[] • Boolean[] • bool[] • Byte[] • String[] • Datetime[] • List<UInt16> • List<Int16> • List<Int32> • List<Int64> • List<Int> • List<Char> • List<Single> • List<Decimal> • List<Float> • List<Double> • List<Boolean> • List<bool> • List<Byte> • List<String> • List<Datetime> • List<SByte> • List<UInt32> • List<UInt64>
	<hr/> <p>Note: The C# IList data type is not supported and does not work with the Automation 360 List data type.</p> <hr/>

Variable type as input or output parameters	Supported data types in .NET
Table	<ul style="list-style-type: none">• UInt16[,]• Int16[,]• Int32[,]• Int64[,]• Int[,]• Char[,]• Single[,]• Decimal[,]• Float[,]• Double[,]• Boolean[,]• bool[,]• Byte[,]• String[,]• Datetime[,]• Byte[,]• UInt32[,]• UInt64[,] <hr/> <p>Note: The Table type variable is equivalent to a two-dimensional array type variable in .NET.</p> <hr/>

Variable type as input or output parameters	Supported data types in .NET
Dictionary	<ul style="list-style-type: none"> • Dictionary<String,UInt16> • Dictionary<String,Int16> • Dictionary<String,Int32> • Dictionary<String,Int64> • Dictionary<String,Int> • Dictionary<String,Char> • Dictionary<String,Single> • Dictionary<String,Decimal> • Dictionary<String,Float> • Dictionary<String,Double> • Dictionary<String,Boolean> • Dictionary<String,bool> • Dictionary<String,Byte> • Dictionary<String,String> • Dictionary<String,Datetime> • Dictionary<Int,String> • Dictionary<Decimal,String> • Dictionary<Boolean,String> • Dictionary<String,SByte> • Dictionary<String,UInt32> • Dictionary<String,UInt64> <hr/> <p>Note: When creating the .Net DLL function, use the IDictionary data type instead of the Dictionary data type.</p> <hr/>

Related tasks

[Example of using the DLL package](#) on page 3081

Build a very simple DLL that will generate a message. Create a bot to run the DLL.

Related reference

[DLL package updates](#) on page 832

Review the updates in released versions of the DLL package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Close action

The Close action in the DLL package enables you to close the DLL reference.

Settings

Closes the current session. In the **Session name** field, enter the name of the session.

Open action

The Open action in the DLL package enables you to open the reference file.

Settings

- In the **File path** field, specify the location of the path.
- Select any of the following tabs to specify the location of the DLL you want to use:
 - **Control Room file**: Use a DLL that is available in the Control Room.
 - **Desktop file**: Use a DLL that is available on a device.
 - **Variable**: Use a file variable to specify the location of the DLL.
- Select any of the following tabs to create a DLL session:
 - **Local session**: Specify a session name that can be used only in the current bot.
 - **Global session**: Specify a session name that can be used across multiple bots such as parent bots, child bots, and other child bots of the parent bots.
See [Sharing sessions across bots](#) on page 2417.
 - **Variable**: Specify a session variable that can be used to share that session with other child bots.

When you run the bot, it passes the session variable to the child bot, which enables the child bot to use the DLL opened in the parent bot.

Note: The DLL package supports only DLLs written in C#.

Sharing sessions across bots

You can share a session across multiple bots so that you can use the same DLL, Microsoft Excel worksheet, and terminal across these bots. You can share a session across child bots, parent bots, and other child bots of the parent bots.

Use the **Global session** option in the **Open** action of the DLL package to pass on the exact state of an application or DLL from one bot to another bot and vice versa.

Sharing a session eliminates the need to repeatedly open and close a session when using the same file across multiple bots. When you share a session across bots, all subsequent actions in that bot, child bots, parent bots, and other child bots of the parent bots can use that DLL session without any additional steps by using the same global session name in these bots.

For example, consider you have added the **Open** action with the **Global session** selected at the eighth line of a bot. All the actions that are executed after the eighth line in the current bot, child bots, and parent bots can use that DLL session without any additional step.

Note: Use the **Open** action to open a global session as the first action in your bots.

Using the Run function (Legacy) action

Use the **Run function (Legacy)** action to run a function within the .dll file and specify the parameters to pass a function and store the output as a variable.

- Use a dictionary variable to pass the parameters to a function. The dictionary key contains the parameter name to pass to a function.
- If the .dll file uses .NET functions or classes from another .dll file, you must add the second .dll file as a manual dependency of the bot.

[Bot dependencies](#) on page 2268

- When you use **Run function** or the **Run function (Legacy)** action, ensure that you use the supported data types for DLL functions.

See [DLL package](#) on page 2411.

Follow these steps to run a function:

1. In the **Actions** palette, double-click or drag the **Run function (Legacy)** action from the **DLL** package.
2. In the **Session name** field, enter the name of the session.
3. In the **Enter the namespace** field, specify the namespace.
You can specify any of the namespaces defined in the DLL file.

Note: Ensure that the value you have provided in the field is correct.

Important: This field is case-sensitive.

4. In the **Enter the class name** field, specify the name of the class.
You can specify the name of any classes available in the namespace.

Important: This field is case-sensitive.

5. In the **Enter the name of function to be executed** field, specify the name of the function to execute.
Ensure that the name you have provided is correct and available in the class specified in the previous step.

Important: This field is case-sensitive.

6. Optional: In the **Parameters to the function** list, select the variable that contains all the parameters needed by the function.
You can use Boolean, datetime, dictionary, list, number, string, or table variable types to pass parameters to the function.

Note: Use the dictionary subtype Any to enable the bot to pass parameters of different data types to the function including Boolean, numeric, and string.

Specify the dictionary key as the parameter name to provide the dictionary value as the parameter value. For example, you have a function `ReturnSum` that returns the sum of two numeric values and want to pass `Param1` and `Param2` as its parameters. Configure a dictionary variable with two keys: `Param1` and `Param2`, each with the value that you want to pass.

7. Optional: In the **Assign output to variable** list, select a variable to use to store the output of the function.
You can use Boolean, datetime, dictionary, list, number, string, or table variable types to store the output based on the type of output the function returns.
8. Click **Save**.

Using the Run function action

Use the **Run function** action to run a function within a .dll file and specify the parameters to pass a function and store the output as a variable.

- This action enables you to pass a parameter of any type. If you want to use a dictionary variable to pass the parameters to a function, use the **Run function (Legacy)** action.

[Using the Run function \(Legacy\) action](#) on page 2418

- The **Run function** action does not support the use of Windows Forms.
- If the .dll file uses .NET functions or classes from another .dll file, you must add the second .dll file as a manual dependency of the bot.

[Bot dependencies](#) on page 2268

- This action supports overloaded functions starting from Enterprise A2019.17. The action can handle .dll files that contain multiple functions of the same name. It calls the function based on the number of parameters passed.
- When you use **Run function** or the **Run function (Legacy)** actions, ensure that you use the supported data types for DLL functions.

[DLL package](#) on page 2411

Perform the follow steps to run a function:

1. In the **Actions** palette, double-click or drag the **Run function** action from the **DLL** package.
2. In the **Session name** field, enter the name of the session.
3. In the **Enter the namespace (Optional)** field, specify the namespace.
You can specify any of the namespaces defined in the DLL file.

Note: Ensure that the value you have provided in the field is correct.

Important: This field is case-sensitive.

4. In the **Enter the class name** field, specify the name of the class.
You can specify the name of any of the classes available in the namespace.

Important: This field is case-sensitive.

5. In the **Enter the name of function to be executed** field, specify the name of the function to execute.
Ensure that the name you have provided is correct and available in the class specified in the previous step.

Important: This field is case-sensitive.

6. Optional: In the **Input parameters** section, click the **Add Parameters** button.

- a) In the **DLL parameter details** dialog box, in the **Parameter name** field, enter the name of the parameter.
- b) From the **Parameter type** list, select a data type.
For Integer data type (UInt16, Int16, Int32, Int64, Int, Single, Float, Decimal, Double, UInt32, or UInt64), you can use a value from a credential vault or a credential variable as input parameter.
- c) In the **value** field, enter the value that you want to pass .
If you select the Integer data type, you can choose from the following options:
 - **Number**: In the number field, enter the value that you want to pass.
 - **Credential**: To use a value from a credential vault, select **Credential**. To use a credential variable, select **Variable**.

For more information about credential vaults and how to use them, see [Credentials and lockers in the Credential Vault](#) on page 1796.

Repeat Step 6 to add multiple parameters.

Important: The names of the parameters you add and their order must be the same as in the DLL function.

7. Use the **Run function in background** option when no Windows system-related operations, such as such as keystroke, mouse click, or window switching, are called under the C# DLL. You can select the **Run function in background** check box to bypass the intermediate window (AAZeroSizeForm) and run the C# DLL under the console application without the form. We recommend that you select this check box if the DLL function is not interacting with the Windows API to perform operations such as keystroke, mouse click, or window switching. This feature also helps to improve the performance of the DLL execution if the **Run function in background** check box is selected.
8. Optional: In the **Assign output to variable** list, select a variable to use to store the output of the function.
You can use Boolean, datetime, dictionary, list, number, string, or table variable types to store the output based on the type of output the function returns.
9. Click **Save**.

Document Classifier package

Document Classifier package enables you to group or classify documents into appropriate learning instances for content extraction in Automation 360 IQ Bot.

Note:

- From Automation 360 v.30 onwards, the IQ Bot Classifier package is renamed to Document Classifier package.
- You can download the Document Classifier package from [IQ Bot downloads](#) link.

Classifier (Number of pages) license is required to process documents against any of the associated actions of the Document Classifier package.

The Document Classifier package enables you to segregate different types of documents into respective categories. This output can then be used to build logic to merge pages in a document for enhanced data extraction.

See [How to merge documents in IQ Bot Classifier package \(A-People login required\)](#).

Actions in the Document Classifier package

The package contains the **Classify**, **Classify documents**, and **Train Classifier** actions. You can use these actions to create a model file, and use the file to classify uploaded documents into different folders. These actions work as a precursor to document processing.

Actions	Description
Classify	IQ Bot Classify action groups the pages of an input document based on the model file that was created using IQ Bot Train Classifier action. See Using Classify action on page 2421
Classify documents	The IQ Bot Classify document action groups the input documents based on the first page of each document, using the selected model file that is created with the IQ Bot Train Classifier action. Use this action if you are manually creating document groups. See Using the Classify document action on page 2423
Train Classifier	See Using Train Classifier action on page 2424

Watch the following video to understand how to use the Document Classifier package:

To learn more, review the courses in IQ Bot Developer learning trail: [IQ Bot Developer Training \(A-People login required\)](#).

Related concepts

[About the Classifier](#) on page 3551

Learn about how documents are classified and the factors that affect classification.

Using Classify action

IQ Bot Classify action groups the pages of an input document based on the model file that was created using IQ Bot Train Classifier action.

- If you have not done so already, use the **Train Classifier** action to create a model file. See [Using Train Classifier action](#) on page 2424.
- Ensure the input files are in PDF format. If the input file is an image file (.gif, .jpg, .png, or .tiff), convert the image to a PDF. See [Using Convert Image To PDF action](#) on page 2638.

Build a bot with the **Classify** action within a **Loop** action to iteratively classify each file in the selected folder.

1. In the Actions palette, double-click or drag the **Loop** action from the **Loop** package.

2. In the **Loop Type** field, select the **Iterator** option.
3. In the **Iterator** field, select **For each file in folder** from the drop-down list.
4. In the **Folder path** field, select the path to the folder that contains the input files.
5. In the **Assign file name and extension to this variable** field, create or select a dictionary variable to store the names and extensions of the files in the selected folder path.
For this example, we will use a dictionary variable named dictFile.
6. In the **Actions** palette, double-click or drag the **Classify** action from the **Document Classifier** package.
7. In the **Input file** field, enter a dynamic file path using a variable.
 - a) Add a file path pointing to the folder, for example `C:\input\`.
 - b) Add the dynamic file name string: `dictFile (name) $.dictFile (extension) $`.

Note: Be sure to include a period between the variable holding the file name and the one holding the extension.

The name and extension keys are predefined. When inserted and run in a loop, the action iterates through the entire folder and calls the files in the folder one at a time. The **Input file** value looks like this: `C:\input\dictFile (name) $.dictFile (extension) $`

8. In the **Classifier** field, provide the file path to the model file.
You can either select the `.zip` folder or extract the `.icmf` file from this folder and select it.

Note: For better classification results and performance, we recommend that you use the `.icmf` file available in the `.zip` folder obtained from the **Train Classifier** action.

9. Use the **Output folder path** option to save the classification output document.
10. Optional: Configure the following **ADVANCED SETTINGS**:
 - **Confidence threshold (%)**: If the confidence value of the category prediction of a page is less than the confidence threshold, it is moved to the `Unclassified` folder.
 - **Save classification output variable**: Save the classification results as a list of dictionaries with the following keys:
 - fileName
 - pageIndex
 - category
 - confidence

Note:

- You can select the type of classification in the Document Classifier:
 - Image-based classification
 - Text-based classification
 - Both image and text-based classification
- To project a higher confidence threshold, we suggest that you calculate the confidence threshold when the document pages are similar. To determine the required confidence threshold, you can review the confidence values from the classification output.

- The Document Classifier can auto-detect the language for classification, and supports all languages supported by ABBYY (an optical character recognition application).

11. Click **Save and **Run**.**

The pages from the output document are saved in the respective subfolders, based on the categories created in the model file. Any previously-classified documents in the output folder will be overwritten.

You can use each subfolder of similar documents to create and train a learning instance to extract data from the documents. See [Create a learning instance](#) on page 3554.

Using the Classify document action

The IQ Bot Classify document action groups the input documents based on the first page of each document, using the selected model file that is created with the IQ Bot Train Classifier action. Use this action if you are manually creating document groups.

- Build and run a bot with the **Train Classifier** action to create a model file. See [Using Train Classifier action](#) on page 2424.
- [Create a new document group](#) on page 3553

1. In the **Actions** palette, double-click or drag the **Classify document** action from the **Document Classifier** package.
2. In the **Input file** field, provide the default filepath for incoming files for classification.
3. In the **Classifier** field, provide the filepath of the model file.

You can either select the `.zip` folder or extract the `.icmf` file from this folder and select it.

Note: For better classification results and performance, we recommend that you use the `.icmf` file available in the `.zip` folder obtained from the **Train Classifier** action.

4. Use the **Output folder path** option to save the classification output documents. The pages from the output document are saved in the respective subfolders based on the categories created in the model file.
5. Optional: Configure the **Confidence threshold (%)**.
If the confidence value of the category prediction of a document is less than the confidence threshold, the document is moved to the `Unclassified` folder.
6. Select from **Normal mode** or **Express mode**.
 - **Normal mode:** The Classifier parses the entire document and groups it based on the fields in all the pages.
 - **Express mode:** The Classifier groups the document based on the fields in the first page.
7. Select or create a list variable to hold the output.
The classification results as a list with the following keys:
 - `fileName`
 - `pageIndex`
 - `category`
 - `confidence`

Using Train Classifier action

Use the **Train Classifier** action to create a model file that is used by the **Classify** action to sort the documents into required categories for input.

Before building the bot, collect example documents and categorize them into folders. Ensure the set of example documents meets the following requirements:

- Has at least two categories.
- A minimum of 15 pages per category (20 pages recommended).
- Split input PDF documents that have multiple pages into single-page PDF documents. See [Using the Split document action](#) on page 2771.

For example, if you have a PDF document that has three pages, split it into three single-page PDF documents.

If these minimum requirements are not met, an error message is displayed during bot runtime.

Each folder has a selection of documents that are a sample of the documents that the associated learning instance will process. The **Train Classifier** action will read through the files in the folders, and build a model based on the documents stored inside each folder.

Note: As ABBYY FineReader Engine OCR is now downgraded to version 12.2 from version 12.4, older `.icmf` files cannot be used to retrain models in Automation 360 v.24 of the Document Classifier package. If you want to add more categories or more files into your existing categories, you must create a new model.

1. In the **Actions** palette, double-click or drag the **Train Classifier** action from the **Document Classifier** package.
 2. Click **Train** to continue creating a new model file.
 3. Optional: If you have an existing model file, click **Re-Train**.
 - a) Use the **Training folder path** field to select an existing folder path from the **Desktop folder** tab.
Alternatively, click the **Variable** tab to manually enter an existing training folder path.
 - b) Use the **Existing zip path** field to select the filepath of the `.zip` folder from **Control Room file** or **Desktop file** tab.
Alternatively, click the **Variable** tab to manually enter the path for the `.zip` folder.
-

Note: When you train documents, a `.zip` folder is created, which contains `.icmf`, `.data` and `.properties` files. Ensure you upload the entire `.zip` folder for retraining an existing model file.

4. Select the input folder path from **Desktop folder** or **Variable**.

The input folder path must have subdirectories with the names that correspond to the category of the documents that you want to train the classifier on. For example, if you have sales-related documents, the input folder path must have subfolders such as `Invoice` and `Purchase Order`.

5. Optional: If you select **Desktop file**, click **Browse** to change the default filepath.
6. Enter a name for the model file in the **Model name** field.
7. Use the **Model output path** field to select the directory for the output model file.
8. Optional: Configure the following **ADVANCED SETTINGS**:

- a) **Training Optimization:** Use the drop-down menu to select the type of training optimization.
- **Precision:** select this option when you want your training model to be precise but can miss out on few documents.
 - **Recall:** select this option when you want the training model to find all the relevant cases within a dataset.
 - **F1 score:** is selected by default and the recommended setting as it combines the training optimization of both **Precision** and **Recall**.

F1 score is the selected by default. **Precision** and **Recall**.

- b) **Classification Type:** Use the drop-down menu to select the features you want to include such as text, image, or both.

Text and image is selected by default. If you select **Text** or **Text and image**, list of supported languages is displayed in the **Recognition Language** drop-down menu.

- c) **OCR Settings:** The **Extract all text blocks** and **Extract text from images** are enabled by default.

With the **OCR Settings** enabled by default, more time is consumed by OCR in extracting the content. This ensures that relatively lower quality documents are also handled based on the inputs from OCR.

9. Click **Save** and **Run**.

When you retrain an existing model, you fetch the already trained data and combine it with new data generated from the text or layout features from input documents. After this, you must train the machine learning model from scratch. This method allows you to save the time needed to re-generate text data or layout data for already trained documents. However, the computationally expensive part is training the machine learning model, hence re-train method is expected to be time-consuming. In case this becomes a constraint, we recommend that you create additional model files and use them for additional training and classification.

The model is created as a `.icmf` file in the directory specified in the **Model output path** field.

After creating the model, build a bot to classify input documents. See [Using Classify action](#) on page 2421

Document Extraction package

The Document Extraction package enables you to extract data from documents and download that data. This package is for processing documents in Document Automation.

When a new learning instance is created, the Control Room automatically creates a folder with the same name as the learning instance in the **Automation > Document Workspace** folder. Within that folder, the Control Room creates the following two bots:

- Extraction bot: Extracts data from defined fields in uploaded documents.
- Download bot: Downloads the extracted data to a specific folder on the device or shared network.

Note: The Process Documents action, that was previously accessible from the now deprecated IQ Bot [Local Device] and IQ Bot Extraction package, provides functionality similar to the Extract Data action in the Document Extraction package.

Actions in the Document Extraction package

This package includes the following actions:

Action	Description
Download data	See Download data action on page 2430
Extract data	See Extract data action on page 2428
Get document data	See Get document data action on page 2426
Update document data	See Update document data action on page 2427

Related concepts

[Document Automation](#) on page 3455

Document Automation is the new Cloud-native intelligent document processing solution that business users can set up to automatically read and process documents quickly using pretrained models and validation feedback.

Related tasks

[Create a learning instance in Document Automation](#) on page 3472

Begin processing documents by creating a learning instance to extract data from invoices, utility bills, or receipts. A learning instance is a structure that holds information such as document type, language, and the fields to be extracted.

Related information

[IQ Bot \[Local Device\] package \(Archived\)](#)

Get document data action

Use the **Get document data** action to retrieve document information such as extracted values and coordinates, from the server.

Based on your requirements, use this action to:

- Retrieve data
- Enable applications for custom validation, lookups, normalization, and data manipulation

Note:

- Bot Runner machine must have Python installed to use the Python package.
- Based on your use case, you can apply custom logic at any stage in a process or workflow.

The following table describes the action fields:

Fields	Description
Document ID	Specify the ID of the document from which you want to get the data. The Document ID is the output of the extraction Task Bot which is available at the process level.
Records	Captures the output of the Get document data action as a record set which contains the following key values: <ul style="list-style-type: none"> • Dictionary object: DocumentDictionary • JSON string representing the document: DocumentJson • Status: Status • Error message: StatusMessage

Update document data action

Use the **Update document data** action to customize and validate data based on external sources. You can update document data in the downloaded dictionary or JSON file and upload it to the server.

Based on your requirements, use this action to:

- Update the document data using custom logic and upload it to the server
- Enable applications for custom validation, lookups, normalization, and data manipulation

Note: Based on your use case, you can apply custom logic at any stage in a process or workflow.

The following table describes the action fields:

Fields	Description
Document ID	Specify the ID of the document to which you want to upload the updated data to. The Document ID is the output of the extraction Task Bot which is available at the process level.
Document data input	The output of the Get document data action is a JSON or dictionary file which contains updated data or coordinates.

Fields	Description
Records	<p>Captures the output of the Get document data action as a record set which contains the following key values:</p> <ul style="list-style-type: none"> • Dictionary object: DocumentDictionary • JSON string representing the document: DocumentJson • Status: Status • Error message: StatusMessage

Consider the following points when you use the **Update document data** action:

- If an error occurs while parsing the input Dictionary or JSON string, this action does not update the document and returns an error message and the validation status.
- If you parse the input Dictionary JSON string and if there are validation rule errors, this action does not update the document but returns the validation status.
- Does not validate entire document against the defined validation rules.
- Replaces original document with the updated one. Hence, if the user does not provide values for some fields, the values for those fields remain empty.

Extract data action

Task Bots use the Extract data action to process documents uploaded to Document Automation.

When you create a learning instance in Document Automation, the Control Room automatically creates the **extractionbot**. To edit this bot, navigate to **Automation > Document Workspace**, select the folder with the same name as the learning instance, and open **extractionbot**.

The following table describes the action fields.

Note: We do not recommend changing the variables in these fields as that might break the process.

Field	Description
Document to extract	File path to the uploaded document
Learning instance name	Name of the learning instance associated with this bot

Field	Description
Output results	<p>Specify where to store the Document Automation data. Based on your use case, you can either upload the data to the Document Automation server, or save it to your local folder.</p> <ul style="list-style-type: none"> • Upload to the Document Automation server: Data generated during extraction is uploaded to the server for further processing (such as validation) and later downloaded by a bot running the Download data action. • Save to your local folder: Data generated by Document Automation is not sent to the server, but is saved to the specified folder path. <hr/> <p>Note: If you select this option, Document Automation does not send files for validation, since that requires the use of the Document Automation server. In addition, you can remove the bot running the Download data action from the process, as selecting this option makes that step in the process bot redundant.</p> <hr/>
Service account	If the learning instance associated with this bot processes documents in Google Document AI , click Pick to select the credential that contains your Google Document AI security token.
Document AI endpoint URL	If the learning instance associated with this bot processes documents in Google Document AI, provide the URL for your service account.
GroupLabel (optional)	If the learning instance was created in Automation 360 IQ Bot and connected to Document Automation, this field is auto-filled with the applicable document group name.

Related tasks

[Create a learning instance in Document Automation](#) on page 3472

Begin processing documents by creating a learning instance to extract data from invoices, utility bills, or receipts. A learning instance is a structure that holds information such as document type, language, and the fields to be extracted.

Configure Extract action to process documents in Google Document AI

Provide the credential that is holding the Google Document AI API key to the **Extraction bot**.

- [Configure key for Google Document AI](#) on page 3471
- [Create a learning instance in Document Automation](#) on page 3472
- Login to your Google Document AI account, navigate to the processor, and set the default version to pretrained-invoice-v1.1-2021-04-09
- Copy the Google Document AI prediction endpoint

Note: When creating a learning instance of **Document Type** as Invoices or Receipts with the **Provider** as Google Document AI for a BYOK scenario, you must include the processor URL with Google Document AI v1.3 in the extraction command configuration.

1. Navigate to **Automation > Private tab > Document Workspace** and click the folder with the same name as the learning instance to configure the bot.
2. Open the **Extraction bot** and click the Document Extraction action to edit it.
3. In the **Service account** field, click **Pick** to select the `doc-ai-credential` credential.
4. Provide the Google Document AI prediction endpoint URL.
5. Click **Save**.

Download data action

Task Bots use the Download data action to download data from successfully processed documents in Document Automation.

When you create a learning instance in Document Automation, the Control Room automatically creates the **downloadbot**. To edit this bot, navigate to **Automation > Document Workspace**, select the folder with the same name as the learning instance, and open the process. By default, the process contains four `downloadbots`. You can edit the output format in the bots: [Change output format from CSV to JSON](#) on page 3484

Important: Edit the bots in the process only. We do not recommend editing the **downloadbot** in the folder with the same name as the learning instance.

The following table describes the **Download data** action fields:

Field	Description
Document Id	The Document ID of the document you want to download

Field	Description
Document type	This is the output file type such as: <ul style="list-style-type: none"> • Output file (CSV): Used for downloading successfully processed documents to CSV format. • Output file (JSON): Used for downloading successfully processed documents to JSON format. • Input file: Used for downloading failed documents in the file type that were uploaded.
Output folder path	Specifies the file path and location to download the document to
Delete files	Removes files from the Document Automation server after they are downloaded

Related reference

[About the Automation Co-Pilot process in Document Automation](#) on page 3479

Document Automation uses Automation Co-Pilot for Business Users technology to manage the end-to-end document extraction process. When you create a learning instance in Document Automation, the system also creates an Automation Co-Pilot process. Review the following guide to understand the logic.

Email package

The Email package contains actions to automate email-related tasks through Exchange Web Services (EWS), Microsoft Outlook, and other email servers. You can use these actions for sending, receiving, and modifying messages, folders, and the status of messages.

Note:

- The Email package supports the email automation of a shared mailbox in Outlook for Office 365/Microsoft 365 using IMAP/EWS protocols, and OAuth 2.0 authentication using Client Credentials and Authorization Code with PKCE grant flows. You can automate emails retrieved from a shared mailbox and perform email-related tasks by accessing each folder(s) and its subfolder(s) in the shared mailbox. Ensure that you have set up the shared mailbox in your Outlook application. Note that sending, forwarding, and replying to emails using a shared mailbox is not supported.
- Proxy is supported for EWS OAuth 2.0. When you create a bot that uses EWS OAuth2 for authentication and the Bot Runner machine is configured behind the firewall, then all outbound requests are routed through the proxy server configured on the Bot Runner machine.
- When you read emails in a loop using a Microsoft Outlook Client connection with a subject filter, the bot cannot read undelivered emails, if the subject contains these receipts:
 - Delivery receipt
 - Read receipt

- Undelivered receipt

Outlook client does not support this feature due to the third-party library it uses.

We recommend that you use **Email server > IMAP** to connect, read and filter such emails.

The Email package supports EWS, POP3, SMTP, and IMAP protocols and enables you to perform the following tasks:

- Manage and organize email messages and folders.
 - Download attachments from emails to specific folders on devices.
 - Extract data from emails to variables, to use as extracted data in other applications. For example, you can extract data from a sender's email and store it in a Microsoft Excel spreadsheet.
-

Note: If you want to automate an email-related task on a device using Microsoft Outlook, ensure that the Outlook application is open.

Note:

- If your current office installation is any of the following:
 - Microsoft 365 Apps for Enterprise
 - Office 2016, 2019, or 2021 (Consumer Version 2009 or later)

Then you do not need to install the Microsoft Access Database Engine as an additional component in your system.

However, if you have both Microsoft 365 Apps and the Microsoft Access Database Engine are installed on your system, then you can uninstall the Microsoft Access Database Engine and repair Microsoft 365 Apps.

Microsoft recommends that you do not install the Microsoft Access Database Engine driver separately because both the Microsoft Access Database Engine 2016 and Microsoft 365 Apps use the same major version identifier (16.0). To learn more about the Microsoft Access Database Engine driver installation requirement, see [Unable to use the Access ODBC or OLEDB provider](#)

- When you send an email, reply, or forward, the attachment size allowed in the email depends on your internet speed (timeout of 120 seconds) and the email server restrictions. If sending an attachment takes more than 120 seconds, the system displays an error due to timeout.
-

Considerations

Note: Some of the actions must be used within a **Loop** action. See [Using the For each mail in mail box iterator](#) on page 2459.

Emails are retrieved based on the sequence of the folders listed in the inbox field. Within each folder, emails are retrieved based on received date and time in the last in, first out (LIFO) order. Additionally, you can apply filters on the following fields:

- Types of emails: **All**, **Read**, and **Unread**
-

- Subject
- From a specific folder
- From specific sender
- Before, on, or after received date

Adhere to the following best practices when you filter and loop through folders that contain a large number of email messages:

- After you have processed email messages, move them to another folder so that their duplicate email messages are not processed again during a subsequent run.
- Try to reduce the number of messages in the mailbox.
- The filtration works on the filter parameters provided by the user, such as type of email: All, Read, and Unread; Subject; from a specific folder; from a specific sender; or before, on, or after received date). Following are the types of filter mechanisms:
 - Email server-side: The filtration that takes place on the server-side is much faster.
 - Client-side: Filtration is performed on the local machine and is comparatively slow because the mail messages are first retrieved from the remote server and then filtered in the local machine.
 - Hybrid: Some parameters are filtered on the server side and some on the client side.
- Here is an explanation of how the filtration process works for various server types:
 - **EWS**: All filtration is done on the server side and is hence much faster.
 - **Outlook client**: Nothing is filtered on the server side, but the filtration process is faster because email messages are already present on the local machine.
 - **IMAP**: Filtration for the **Subject** field is performed on the local machine and is slower. For the **Before, on, or after received date** parameter, the filtration for `date` is performed on the remote server, and for `hour/min/second`, it is performed on the local machine. For example, for the date 01/12/2022, filtration is performed on the remote server whereas for the time (hour/min/sec) 21:10:56, filtration is performed on the local machine.
 - **POP3**: This server is the slowest of all because mails are retrieved from the remote server, and filtration is done in the local machine.

We recommend connecting using the EWS server and Outlook client as the filtration process is much faster when compared to IMAP and POP3 protocols.

- Always use the **Disconnect** action if the **Connect** action is used to release a resource.

Before you start

Perform the following actions within the `Email` package as part of using the set of available actions:

1. Establish a connection with an email server using the **Connect** action.

While establishing the connection, specify the details and session name of the email server. Use this same session name for the other actions.

You do not have to establish a connection for the **Forward**, **Reply**, and **Send** actions because you will add the sender and email server details when you use these actions.

2. Use the actions to automate a task.

3. After you have automated all the email-related tasks, terminate the connection to the mail server using the **Disconnect** action.

Important: You must enable POP settings to automate an email-related task on the Gmail server using the POP3 protocol. See [Read Gmail messages using POP](#).

Actions in the Email package

The Email package includes the following actions:

Action	Description
Change status	See Change status action on page 2435.
Check if folder exists	See Check if folder exists action on page 2435.
Delete all	See Delete all action on page 2436.
Delete	See Delete action on page 2437.
Disconnect	See Disconnect action on page 2437.
Connect	See Using Connect action for Email on page 2437.
Forward	See Using the Forward action on page 2443.
Move all	See Move all action on page 2446.
Move	See Move action on page 2446.
Reply All	See Reply All action on page 2447.
Reply	See Using Reply action on page 2450.
Save all attachments	See Save all attachments action on page 2453.
Save attachments	See Save attachment action on page 2454.
Save email	See Save email action on page 2454.
Send	See Using the Send action on page 2454.

Related reference

[Loop package](#) on page 2679

Use the Loop package to run a sequence of actions repeatedly for a specific number of times or until a specific condition is met.

[Email server settings](#) on page 2442

The details about the mail server you provide when establishing a connection varies based on the email server to which you are connecting.

[Using dictionary variable for email properties](#) on page 2461

When you automate an email-related task, Automation Workspace retrieves various properties of an email and stores the values of these properties in a dictionary variable. These properties are stored in a dictionary variable when you use an email action within a loop action.

[Email package updates](#) on page 837

Review the updates in released versions of the Email package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Change status action

The Change status action in the Email package enables you to change the statuses of emails to read or unread. Use this action within a **Loop** action.

Settings

- In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** .
- **Change status to:** Select the **Read** or **Unread** option to change the status of the email.

Note:

- Microsoft Outlook supports this action.
- POP3 servers do not support and maintain the read or unread status of emails.

Check if folder exists action

Use the Check if folder exists action in the Email package to verify whether a folder with the name you specified exists in the email server.

Settings

- In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** .
- In the **Folder name** field, enter the name of the folder you want to check.

Note: This field is not case-sensitive.

- In the **Select the destination boolean variable** list, select a Boolean variable to store the output of the result. The output is either True (folder exists) or False (does not exist). The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Delete all action

Use the Delete all action in Email package to delete read, unread or all emails from the specified folder.

Settings

- In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** .
- In the **From specific folders (optional)** field, specify the folder from which to delete the emails. For example, `Inbox/folder1; Inbox/folder2` or `Inbox/test*`.

Note:

- Microsoft Outlook does not allow the use of wildcards (*) to run a search on folder filters. You must specify all the folders individually in the **From specific folders** field.
 - Both EWS and email server allow the use of wildcards and supports partial matching. For example, you can specify `Inbox/test*` to match `Inbox/test1`, `Inbox/test2`.
 - If you are using the POP3 protocol, you can delete emails from Inbox only.
-
- Select the **All**, **Read**, or **Unread** option to specify the type of email you want to delete.

Note:

- For an email server using the POP3 protocol, this action deletes all the email messages.
 - Microsoft Outlook does not currently support this action.
-
- Optional: Specify any of the following conditions:

- **When subject contains:** Enter keywords separated by semicolons.

Note: This field is not case sensitive. You can enter keywords in the **When subject contains** field. If you add keywords inside a pair of double quotation marks, the bot will search for an exact match of keywords and the case you used to filter and retrieve emails.

-
- **From specific senders:** Enter senders' email addresses separated by semicolons.
 - **When received date is on or after** or **When received date is before:** Select a datetime variable from the list.

Note: This action is not supported for Gmail because Gmail does not support folders.

Delete action

Use the Delete action in Email package to delete the specified email from the inbox. Use this action within a Loop action.

Settings

In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** .

Note: Microsoft Outlook supports this action.

Disconnect action

Use the Disconnect action in Email package to terminate the connection established with the email server.

Settings

In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** .

Using Connect action for Email

Use the **Connect** action to establish a connection with an email server. This is the first action you must use to automate an email-related task.

You can use OAuth 2.0 to authenticate with the email server for email automation. Based on your email service provider, perform the relevant steps:

- **Outlook/Office 365**
 - If you use **Client credentials flow** authentication mode, then perform the following steps:
 1. Log in to the Microsoft [Azure portal](#).
 2. Register an application with the Microsoft identity platform to obtain the client ID and tenant ID. See [Register an application](#).
 3. Add a Client secret. See [Add a client secret](#).
 4. Based on which mail server you connect to, perform the relevant steps:
 - **IMAP/POP3**

Add the POP and IMAP permissions to your AAD application . See [Authenticate an IMAP, POP or SMTP connection using OAuth](#).
 - **EWS**
 - Configure for app-only authentication. See [Configure for app-only authentication](#).

- Configure an application access policy and limit the scope of application permissions. See [Configure application access policy](#).
- If you use the **Authorization code with PKCE** authentication mode, then perform the following steps:
 1. Log in to the Microsoft [Azure portal](#).
 2. Register an application with the Microsoft identity platform to obtain the client ID and tenant ID. See [Register an application](#).
 3. When registering the application, set the redirect URI to `http://localhost:9999/callback`.
 4. Add permissions with type delegated for IMAP, POP3, and SMTP and grant the application the required permission for Microsoft Graph to the application.

The videos in the following playlist provide information about configuring and using OAuth 2.0 authentication in the Email connect action:

Note: If the mailbox is used inside a **Loop**, ensure that you register the user who is assigned to perform the automation. For more information, see .

- **Gmail**

To authorize your application with Gmail using the **Authorization code with PKCE** authentication method, perform the following steps:

1. Configure the OAuth2.0 settings in the Google Cloud Platform (GCP) and retrieve the necessary credentials to connect Automation 360 with your G Suite applications.
2. If you have not already done so, [create a project](#).
3. To generate the Client ID and Client secret, complete the steps in [Setting up OAuth 2.0](#).

Note:

- Select the **Web application** option.
- Add this authorized redirect URI: `http://localhost:8888/Callback`.

4. Complete the steps to set up [user consent](#) for the username that you will use to connect to the Automation 360.

Note:

- Client Credentials flow does not support Gmail.
- The Client Credentials and Authorization code with PKCE authentication modes do not support Yahoo and MSN mail servers.

Important: If you want to use both the authentication mode (Client credentials and Authorization code with PKCE), you must register on two separate applications.

Note: When you connect to an Exchange Web Services server, multi-factor authentication (MFA) must be disabled, including in all organizational level security policies where MFA might be enabled. If multi-factor is not disabled completely, users can encounter connection or authorization errors. However, if you still want to use MFA, review the information in this article (be aware that a successful connection is not guaranteed):

[Multi-factor authentication for Azure EWS \(A-people login required\)](#)

This action enables you to provide the email server credentials and details, and associate this information with a session name. Use this same session name for the other Email actions, so you only have to provide the server information once.

To establish a connection with an email server, follow these steps:

1. In the **Actions** palette, double-click or drag the **Connect** action from the **Email** package.
2. Enter a session name.
3. In the **Outlook, Email server**, or **EWS** option, specify whether you want to establish a connection with Microsoft Outlook or a mail server.

When you establish a connection with Microsoft Outlook, email messages are processed from the shared mailbox. Ensure that you have set up the shared mailbox in your Outlook application.

Note:

- This feature is supported only for Outlook.
- You can select only one mailbox from the list of mailboxes in the shared mailbox.
- The meeting invitation is not read in Outlook because the bot does not select calendar invites as email objects. This feature is not currently supported.

-
- If you have selected the **Outlook** option, you do not need to provide any additional details.
 - If you have selected the **Email server** option, complete the following fields:

Note: For information about the host and port to be used for the various mail servers, see [Email server settings](#) on page 2442.

-
- **Use secure connection (SSL/TLS):** Select this option if you want to use a secure connection with the mail server.
 - **Host:** Enter the name of the mail server.

Note: This field is not case-sensitive.

-
- **Port:** Enter the port number of the server.
 - **Protocol:** Select either **IMAP** or **POP3** protocol.
 - **Authentication mode:** Choose from the following authentication modes:
 - **Basic:** Uses the username and password.
 - **OAuth2 – Authorization code with PKCE:** See [Microsoft identity platform and OAuth 2.0 authorization code flow](#)

For more information on how to set up application in Azure to use OAuth Authorization Code with PKCE Flow for Mail Server, see [How to setup App in Azure and Exchange Online to use OAuth 2.0 Client Credentials Flow for IMAP/POP3 Mail Server \(A-People login required\)](#).

- **OAuth2 – Client credentials:** See [Microsoft identity platform and the OAuth 2.0 client credentials flow](#)

For more information on how to set up an application in Azure to use OAuth 2.0 Client Credentials Flow for IMAP/POP3 Mail Server, see [How to setup App in Azure and Exchange Online to use OAuth 2.0 Client Credentials Flow for IMAP/POP3 Mail Server \(A-People login required\)](#).

Depending on the authentication mode that you selected, you must specify the details in the following fields as applicable.

- **Username:** Enter the username that you want to use to access the mail server.
For example, `john.smith@myCompanyName.com`
- **Password:** Enter the password for the username you provided.
- For **Client ID**, **Tenant ID**, **Redirect URI**, and **Client secret** fields, enter the information that is provided for your account on your [Azure portal](#).
- **Email provider:** Select your email service provider from the drop-down list.
 - Outlook/Office365
If you select this option, then provide the **Tenant ID**.
 - Gmail

For **Username**, **Password**, **Tenant ID**, **Client ID**, and **Client secret** fields, choose from **Credential**, **Variable**, or **Insecure string** tab:

- **Credential:** Use a value available in the credential vault.
 - **Variable:** Use a user-defined variable that stores the values.
 - **Insecure string:** Manually enter a value.
- If you have selected the **EWS** option, complete the following fields:
 - **Exchange Version:** Select the version that your organization is using:
 - Exchange Server 2013
 - Exchange2010_SP2
 - Exchange2010_SP1
 - Exchange2010
 - Exchange2007_SP1
 - **Azure cloud:** Select the product that your organization is using:
 - **Azure Global:** For customers of Microsoft 365 Commercial version (`login.microsoftonline.com`)
 - **Azure US GCC High:** For customers of Microsoft 365 Government version (`login.microsoftonline.us`)
 - Optional: **Domain name:**
 - If you are an Office 365 customer and you leave this field blank, Automation Workspace uses `smtp.office365.com` to connect to the server.
 - If you are an Office 365 customer and you have entered a domain name in the **username** field, you must enter `smtp.office365.com` in this field.

- If you are not an Office 365 customer, enter the domain name of your organization. Otherwise, Automation Workspace uses the domain name you provided in the **Username** field.
- **Authentication mode:** Choose from the following authentication modes:

Note: From Automation 360v.27 or later, the authorization type **OAuth2-Silent authentication mode** is renamed to **OAuth2-ROPC**, and the **OAuth2-Interactive authentication mode** is renamed to **OAuth2-Implicit**.

- **Basic:** Uses the username and password.
- **OAuth2-ROPC:** See [Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials](#)
- **OAuth2-Implicit:** See [Microsoft identity platform and implicit grant flow](#)
- **OAuth2 – Authorization code with PKCE:** See [Microsoft identity platform and OAuth 2.0 authorization code flow](#)

For more information on how to set up an application in Azure to use OAuth Authorization Code with PKCE Flow for EWS, see [How to setup App in Azure to use OAuth Authorization Code with PKCE Flow for EWS \(A-People login required\)](#).

- **OAuth2 – Client credentials:** See [Microsoft identity platform and the OAuth 2.0 client credentials flow](#)

For more information on how to set up an application in Azure and Exchange Online to use OAuth 2.0 - Client Credentials Flow for EWS Server, see [How to setup App in Azure and Exchange Online to use OAuth 2.0 - Client Credentials Flow for EWS Server \(A-People login required\)](#).

If you have trouble connecting to shared mailbox using EWS, see [Unable to connect to shared mailbox using EWS error \(A-People login required\)](#).

Depending on the authentication mode that you selected, you must specify the details in the following fields as applicable.

- **Username:** Enter the username that you want to use to access the mail server.
For example, `john.smith@myCompanyName.com`
- **Password:** Enter the password for the username you provided.
- For **Client ID**, **Tenant ID**, **Redirect URI**, and **Client secret** fields, enter the information that is provided for your account on your [Azure portal](#).
- **Test connection:** Click **Test connection** to sign in to your account, accept the permissions requested to authenticate, and establish a connection with the server.

Note:

- When you perform a desktop operation and click **Test connection**, variables such as (Credential, Credential variable, or Sting variables) are currently not supported.
- When you perform desktop operation and click **Test connection** to sign in to your account, then add this redirect URI: `https://outlook.office365.com`

For **Username**, **Password**, **Tenant ID**, **Client ID**, and **Client secret** fields, choose from **Credential**, **Variable**, or **Insecure string** tab:

- **Credential:** Use a value available in the credential vault.
- **Variable:** Use a user-defined variable that stores the values.
- **Insecure string:** Manually enter a value.

4. Click **Save**.

Email server settings

The details about the mail server you provide when establishing a connection varies based on the email server to which you are connecting.

The following table provides information about the host name and the port you must use when establishing a connection to the specified mail server:

Server	For reading or retrieving emails	For sending emails
Microsoft Outlook/Microsoft Office 365	Host: outlook.office365.com Port: 993	Host: outlook.office365.com, Port: 993 Host: smtp.office365.com Port: 587
Gmail	Host: imap.gmail.com Port: 993	Host: smtp.gmail.com Port: 587
Yahoo	Host: imap.mail.yahoo.com Port: 993	Host: smtp.mail.yahoo.com Port: 465 or 587
MSN	Host: imap-mail.outlook.com Port: 993 For POP3: Host: pop-mail.outlook.com Port: 993	Host: smtp-mail.outlook.com Port: 465 or 587

The Email package supports nonstandard ports in the range of 1 through 65535 for the SMTP server.

Additional configuration for Gmail and Yahoo

Google no longer supports using less secured apps which only require you to enter your username and password to log in to your Google Account. If you are using a Gmail account to automate an email-related task, you can grant access to third-party applications by using the App password.

You can use the App password if the application does not support Sign in with Google to connect apps to your Google Account. You can only use App passwords with accounts that have 2-Step

Verification turned on. As a best practice, use OAuth 2.0 authentication to access G Suite account data.

For more information on how to generate an app password for Gmail, see [Generate and use app passwords for Gmail](#).

If you are using a Yahoo account to automate an email-related task, you must generate the app password from the Yahoo account security page. You can then use the app password and email address to log in to your email account.

For more information on how to generate an app password for Yahoo, see [Generate and use app passwords for yahoo](#).

Using the Forward action

Use the **Forward** action to forward emails and attachments to one or more recipients. To forward emails as plain text or HTML through Exchange Web Services (EWS), Microsoft Outlook, or other email servers, use this action within a **Loop** action.

To forward emails, follow these steps:

1. In the Actions palette, double-click or drag the **Forward** action from the Email package.
2. In the **To address** field and the optional **Cc** and **Bcc** fields, enter the email addresses of the recipients.

Note: The **To address**, **Cc**, and **Bcc** fields are not case-sensitive.

3. Optional: To specify whether to attach multiple files as a list or create a variable to hold the list values of the file object, select the **List** or **Variable** tab from **Attachment**.

Option	Description
List	<ul style="list-style-type: none"> • Select the attachment from a location: <ul style="list-style-type: none"> • Control Room file: Enables you to select an attachment that is available in a folder. • Desktop profile: Enables you to select an attachment that is available on your device. <p>You can provide a combination of static path or string variable. To use it as a string variable, copy the static path from your desktop and create a variable of type string. Enter the Variable name and paste the file path in the Default value field. Press F2 to insert the value of the filepath.</p> • Variable: Enables you to specify the file variable that contains the location of the attachment. <ul style="list-style-type: none"> • Specify the path that you want to attach in the Value field. Click Add to attach multiple files.

Option	Description
Variable	<p>Enables you to specify the list of file objects that contain the location of the attachments.</p> <p>Create a new variable of type List with subtype File, and add the filepath in the Default value field (optional). You can choose the file from the Desktop or Control room.</p>

When you are attaching multiple files to an email, to separate the file paths, if you are connected with EWS, use a comma (,), and if you are connected to an email server or Microsoft Outlook, use a semicolon (;).

- Optional: Select the **Raise error if attachments are missing (desktop only)** check box to verify that you have attached a file and the attached file exists.

Option	Result
The Raise error if attachments are missing (desktop only) check box is selected	If a file is not attached, the email is not sent and the bot encounters an error.
The Raise error if attachments are missing (desktop only) check box is not selected	The email is sent even if a file is not attached.

- Select the format that you want to use from the following options:

Option	Description
Plain text	Use regular text in your email body, with no formatting effects, such as bold, italic, or underline, or special layout options.
HTML code	Use HTML script in your mail body when you want your content to be displayed in a certain layout every time. You can also include interactive elements, such as links.
HTML design editor	Use this option to create and customize your email layout and body. Use the editor toolbar to make various changes to your text, such as applying bold, italic, and other formatting effects, inserting links, and changing the font and size of the text. You can copy the content from the design editor and paste it to other windows.

- Optional: Enter the content you want to send along with the email in the **Message** field. The email will be appended to the message you have specified.
- Optional: Select the **Include Go Green message at the end of the email** check box. The Go Green message appends the following text to the bottom of the email body: Please consider the environment before printing. Let's Go Green!
- Select the **Email server, EWS** or **Outlook** option from the **Send email via** list to specify whether to send the emails using Microsoft Outlook or a mail server.

- If you have selected the **Outlook** option, you do not need to provide any additional details.
- If you have selected the **Email server** option, complete the following fields:

Note: For information about the host and port to be used for the various mail servers, see [Email server settings](#) on page 2442.

- **Email server host:** Enter the host you want to connect.

Note: If you use the host Outlook.office365.com, there is a limit of 30 messages sent per minute and 10,000 recipients per day.

- **Email server port:** Enter the port you want to use to establish the connection.
- **Use secure connection (SSL/TLS):** Select this option if you want to use a secure connection with the mail server.
- **My server requires authentication:** Select this option if the server requires credentials for access.
- **Authentication mode:** Select the authentication modes:
 - **Basic**
 - **OAuth2 – Authorization code with PKCE**

Depending on the authentication mode that you selected, you must specify the details in the following fields as applicable.

- **Username:** Enter the username that you want to use to access the mail server.
For example, john.smith@myCompanyName.com
- **Password:** Enter the password for the username you provided.
- For **Client ID**, **Tenant ID**, **Redirect URI**, and **Client secret** fields, enter the information that is provided for your account on your [Azure portal](#).
- **Email provider:** Select your email service provider from the drop-down list.
 - Outlook/Office365
If you select this option, then provide the **Tenant ID**.
 - Gmail

For **Username**, **Password**, **Tenant ID**, **Client ID**, and **Client secret** fields, choose from **Credential**, **Variable**, or **Insecure string** tab:

- **Credential:** Use a value available in the credential vault.
- **Variable:** Use a user-defined variable that stores the values.
- **Insecure string:** Manually enter a value.

- If you have selected the **EWS** option, you do not need to provide any additional details.

9. Click **Save**.

Move all action

The Move all action in the Email package enables you to move all emails from one folder to another in the email server.

Settings

- In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** .
- In the **Destination folder path in mailbox** field, provide the path to the location where you want to move the email.
- Select which emails to move: **All**, **Read**, or **Unread**
- In the **From a specific folder** field, specify the folder from which to move the emails. For example, `Inbox/project1`.

Note: For an email server using the POP3 protocol, you can retrieve emails only from the inbox.

- Optional: Specify any of the following conditions:
 - **When subject contains:** Enter keywords separated by semicolons.

[How subject filter works when moving emails](#) on page 2463

Note: The **When subject contains** field is case sensitive. If you have established a connection with the EWS server and when you enter text inside a pair of double quotation marks ("") in the **When subject contains** field, the bot retrieves all the email messages whose subject exactly matches the text and the case that you entered inside a pair of double quotation marks.

- **From specific senders:** Enter senders' email addresses separated by semicolons.
 - **When received date is on or after** or **When received date is before:** Select a datetime variable from the list.
-

Note: Because folders are not supported in Gmail, this action is not supported for Gmail.

Note: You cannot use the **Move all** action within a loop. The **Move all** action is designed to be used with conditions outside a loop.

For more information, see [Can Move all action be used within a loop? \(A-People login required\)](#)

Move action

The Move action in the Email package enables you to move an email from one folder to another in the mailbox. Use this action within a **Loop** action.

Settings

- In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** .

- In the **Destination folder path in the mailbox** field, provide the path to the destination folder where you want to move the email. For example, `Inbox/finance/1`
- Keep the following considerations in mind when you use the **Move** action:
 - You must use this action inside a loop.
 - When you connect with an **Email server** and use the **IMAP** protocol, ensure that you use the **Move** action as the last action in the email loop.
 - This action is not supported for **POP3** connections.
 - The bot encounters an error if the **Delete** action is used before the **Move** action.
 - If you are connecting to Outlook, we recommend that you to use a **Delay** action after the **Move** action. (Specify a maximum delay of more than 2 seconds). Delay is based on Outlook client performance.
 - For improved performance when moving a large number of emails, considering latency issues with the Outlook client, we recommend using the **Move all** action instead of **Move** action when you want to move more than 500 emails.

Reply All action

You can use the **Reply all** action in the Email package to send a response to the sender and include all the recipients of an email with the same or modified subject.

Settings

You use this action in a **Loop** action. This action does not include any files attached to the original email.

1. Optional: In the **Additional Cc** and **Bcc** fields, enter the email address of any additional recipients. Use a comma to separate the multiple email IDs.
2. Optional: Select the **Exclude sender of the email** check box to exclude the email sender from the email recipients while replying to it.
3. Optional: In the **Subject** field, you can enter a new subject line or modify the existing subject while replying to the email.
4. Optional: You can specify whether to attach multiple files as a list, or create a variable to contain the location of any attachments. Select the **List** or **Variable** tab from **Attachment**.

Option	Description
List	<ul style="list-style-type: none"> • Select the attachment from a location: <ul style="list-style-type: none"> • Control Room file: Select an attachment from a folder. • Desktop profile: Select an attachment from your device. <p>You can provide a combination of a static path or string variable. To use it as a string variable, copy the static path from your desktop and create a variable of type String. Enter the Variable name and paste the file path in the Default value field. Press F2 to insert the value of the filepath.</p> <ul style="list-style-type: none"> • Variable: Specify the file variable that contains the location of the attachment. <ul style="list-style-type: none"> • Specify the path that you want to attach in the Value field. Click Add to attach multiple files.
Variable	<p>Specify file variable that contains the location of the attachments.</p> <p>Create a new variable of type List with subtype File, and add the filepath in the Default value field (optional). You can choose the file from the Desktop or Control Room.</p>

5. Optional: Select the **Raise error if attachments are missing (desktop only)** check box to verify that you have attached a file and the attached file exists.

Option	Result
The Raise error if attachments are missing (desktop only) check box is selected	If a file is not attached, the email is not sent and the bot encounters an error.
The Raise error if attachments are missing (desktop only) check box is not selected	The email is sent even if a file is not attached.

6. Select the format that you want to use from the following options:

Option	Description
Plain text	Use regular text in your email body, without any formatting effects, such as: bold, italic, underline, or special layout options.
HTML code	Use HTML script in your email body to display your content using a consistent layout every time. You can also include interactive elements, such as links.
HTML design editor	Use to create and customize your email layout and body. You can use the editor toolbar to change your text, such as applying bold, italic, and other formatting effects, inserting links, and changing the text font and size of the text. You can copy the content from the design editor and paste it to other browser locations.

7. Enter the content you want to send with the email in the **Message** field.
The email will be appended to the message you specified.
8. Optional: Select the **Include Go Green message** at the end of the email check box.
The Go Green message appends the following text to the bottom of the email body: `Please consider the environment before printing. Let's Go Green!`.
9. Select the **Email server**, **EWS**, or **Outlook** option from the **Send email via** list to specify whether to send the emails using Microsoft Outlook or a mail server.
 - If you selected the **Outlook** option, you do not need to provide any additional details.
 - If you selected the **Email server** option, enter information for the following fields:

Note: For information about which host and port to use for the various mail servers, see [Email server settings](#) on page 2442.

- **Email server host:** Enter the host you want to connect.

Note: If you use the host Outlook.office365.com, there is a limit of 30 messages sent per minute, and 10,000 recipients per day.

- **Email server port:** Enter the port you want to use to establish the connection.
- **Use secure connection (SSL/TLS):** Select this option to use a secure connection with the mail server.
- **Authentication mode:** Select the authentication modes:
 - **Basic**
 - **OAuth2 – Authorization code with PKCE**

Depending on the authentication mode that you select, you must specify the any applicable details in the following fields:

- **Username:** Enter the username used to access the mail server.

For example, john.smith@myCompanyName.com

- **Password**: Enter the password for the username you provided.
- For **Client ID**, **Tenant ID**, **Redirect URI**, and **Client secret** fields, enter the information that is provided for your account on your [Azure portal](#).
- **Email provider**: Select your email service provider from the drop-down list.
 - Outlook/Office365
If you select this option, then enter the **Tenant ID**.
 - Gmail

For **Username**, **Password**, **Tenant ID**, **Client ID**, and **Client secret** fields, choose from the **Credential**, **Variable**, or **Insecure string** tab:

- **Credential**: Use a value available in the credential Vault.
 - **Variable**: Use a user-defined variable that stores the values.
 - **Insecure string**: Manually enter a value.
- If you have selected the **EWS** option, you do not need to provide any additional details.

Using Reply action

Use the **Reply** action to send a response to an email with the same subject.

To send a reply to emails as plain text or HTML through Exchange Web Services (EWS), Microsoft Outlook, or other email servers, use this action within a **Loop** action. This action does not include any files attached to the original email.

Follow these to reply to an email:

1. In the **Actions** palette, double-click or drag the **Reply** action from the **Email** package.
2. In the **Cc** and **Bcc** fields, enter the email address of additional recipients.

Note: The **Cc** and **Bcc** fields are not case sensitive.

3. Optional: To specify whether to attach multiple files as a list or create a variable to hold the list values of the file object, select the **List** or **Variable** tab from **Attachment**.

Option	Description
List	<ul style="list-style-type: none"> • Select the attachment from a location: <ul style="list-style-type: none"> • Control Room file: Enables you to select an attachment that is available in a folder. • Desktop profile: Enables you to select an attachment that is available on your device. <p>You can provide a combination of static path or string variable. To use it as a string variable, copy the static path from your desktop and create a variable of type string. Enter the Variable name and paste the file path in the Default value field. Press F2 to insert the value of the filepath.</p> • Variable: Enables you to specify the file variable that contains the location of the attachment. <ul style="list-style-type: none"> • Specify the path that you want to attach in the Value field. Click Add to attach multiple files.
Variable	<p>Enables you to specify the list of file objects that contain the location of the attachments.</p> <p>Create a new variable of type List with subtype File, and add the filepath in the Default value field (optional). You can choose the file from the Desktop or Control room.</p>

When you are attaching multiple files to an email, to separate the file paths, if you are connected with EWS, use a comma (,), and if you are connected to an email server or Microsoft Outlook, use a semicolon (;).

4. Optional: Select the **Raise error if attachments are missing (desktop only)** check box to verify that you have attached a file and the attached file exists.

Option	Result
The Raise error if attachments are missing (desktop only) check box is selected	If a file is not attached, the email is not sent and the bot encounters an error.
The Raise error if attachments are missing (desktop only) check box is not selected	The email is sent even if a file is not attached.

5. Select the format that you want to use from the following options:

Option	Description
Plain text	Use regular text in your email body, with no formatting effects, such as bold, italic, or underline, or special layout options.
HTML code	Use HTML script in your mail body when you want your content to be displayed in a certain layout every time. You can also include interactive elements, such as links.
HTML design editor	Use this option to create and customize your email layout and body. Use the editor toolbar to make various changes to your text, such as applying bold, italic, and other formatting effects, inserting links, and changing the font and size of the text. You can copy the content from the design editor and paste it to other windows.

6. Enter the content you want to send along with the email in the **Message** field.
The email will be appended to the message you have specified.
7. Optional: Select the **Include Go Green message at the end of the email** check box.
The Go Green message appends the following text to the bottom of the email body: `Please consider the environment before printing. Let's Go Green!`
8. Select the **Email server**, **EWS** or **Outlook** option from the **Send email via** list to specify whether to send the emails using Microsoft Outlook or a mail server.
 - If you have selected the **Outlook** option, you do not need to provide any additional details.
 - If you have selected the **Email server** option, complete the following fields:

Note: For information about the host and port to be used for the various mail servers, see [Email server settings](#) on page 2442.

- **Email server host:** Enter the host you want to connect.

Note: If you use the host Outlook.office365.com, there is a limit of 30 messages sent per minute and 10,000 recipients per day.

- **Email server port:** Enter the port you want to use to establish the connection.
- **Use secure connection (SSL/TLS):** Select this option if you want to use a secure connection with the mail server.
- **My server requires authentication:** Select this option if the server requires credentials for access.
- **Authentication mode:** Select the authentication modes:
 - **Basic**
 - **OAuth2 – Authorization code with PKCE**

Depending on the authentication mode that you selected, you must specify the details in the following fields as applicable.

- **Username:** Enter the username that you want to use to access the mail server.
For example, `john.smith@myCompanyName.com`
- **Password:** Enter the password for the username you provided.

- For **Client ID**, **Tenant ID**, **Redirect URI**, and **Client secret** fields, enter the information that is provided for your account on your [Azure portal](#).
- **Email provider**: Select your email service provider from the drop-down list.
 - Outlook/Office365
If you select this option, then provide the **Tenant ID**.
 - Gmail

For **Username**, **Password**, **Tenant ID**, **Client ID**, and **Client secret** fields, choose from **Credential**, **Variable**, or **Insecure string** tab:

- **Credential**: Use a value available in the credential vault.
 - **Variable**: Use a user-defined variable that stores the values.
 - **Insecure string**: Manually enter a value.
- If you have selected the **EWS** option, you do not need to provide any additional details.

9. Click **Save**.

Save all attachments action

Use the **Save all attachments** action to save attachments from all emails on the email server to a specified folder.

Settings

- In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** .
- Select which emails to save: **All**, **Read**, or **Unread**.
- In the **Save attachments to folder** field, specify the location to save the attachments.

Note: This field is not case-sensitive.

- **Overwrite file(s)**: Select this option to overwrite an existing file with the same name. If this option is not selected, the downloaded attachment is saved with the same filename suffixed with a numeric value; it does not overwrite the existing file.

Note:

- You can save attachments with a filename that contains a TAB character.
 - If connected to an Outlook server, images embedded in the emails are downloaded along with attachments.
-

Save attachment action

Use the **Save attachment** action to save attachments from one email to a specified folder. Use this action within a **Loop** action.

Settings

- In the **Save attachments to folder** field, specify the location to save the attachments.

Note: This field is not case-sensitive.

- **Overwrite file(s):** Select this option to overwrite an existing file with the same name. If this option is not selected, the downloaded attachment is saved with the same filename suffixed with a numeric value; it does not overwrite the existing file.

Note: If connected to an Outlook server, images embedded in the emails are downloaded along with attachments.

Save email action

Use the Save email action in the Email package to save an email message as an EML file to a folder. Use this action within a **Loop** action.

Settings

- In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** .
- In the **Save emails to folder** field, specify the location to save the email.

Note: This field is not case-sensitive.

- **Overwrite file(s):** select this option to overwrite the existing file with the same name. If this option is not selected, the email message is saved with the same filename suffixed with a numeric value; it does not overwrite the existing file.

Note: Microsoft Outlook supports this action.

Using the Send action

Use the **Send** action to send an email. This action enables you to send an email to one or more recipients from Microsoft Outlook or a mail server, attach files, and select to send the email in plain text or HTML format.

The **Send** action enables you to attach multiple files of various formats to an email. There is no restriction on the type of file you can attach or its size. However, restrictions implemented by the mail server you are using to send an email apply. For example, a task will fail if the files you have attached to the email you are sending do not adhere to the restrictions applied by the mail server.

Note: Attachments sent as part of email automation are subject to the policies and rules set at the level of the proxy server, firewall, antivirus, email server, customer environment, and so on.

To send an email from a Gmail or Yahoo account, enable access to a less secure app for that account. See [Email server settings](#) on page 2442.

1. In the **Actions** palette, double-click or drag the **Send** action from the **Email** package.
 2. In the **To address** field and the optional **Cc** and **Bcc** fields, enter the email addresses of the recipients.
-

Note: The **To address**, **Cc**, and **Bcc** fields are not case-sensitive.

3. When you send an email, and if you are uncertain about the validity or activation of any user email address, you can select the **Raise error if the email ids are invalid** option. When you select the **Raise error if the email ids are invalid** option and execute, the bot will display an error message if any invalid or deactivated email IDs are found.
-

Note: Depending on the email server connection, the bot might or might not detect an invalid or deactivated email ID.

4. In the **Subject** field, enter the subject for the email.
 5. Optional: To specify whether to attach multiple files as a list or create a variable to hold the list values of the file object, select the **List** or **Variable** tab from **Attachment**.
-

Note: When you create a bot, if the attachment includes the less-than symbol (<) as a special character in the filepath, the special character will be removed after bot execution because the Windows operating system does not support this special character.

Option	Description
List	<ul style="list-style-type: none"> Select the attachment from a location: <ul style="list-style-type: none"> Control Room file: Enables you to select an attachment that is available in a folder. Desktop profile: Enables you to select an attachment that is available on your device. <p>You can provide a combination of static path or string variable. To use it as a string variable, copy the static path from your desktop and create a variable of type string. Enter the Variable name and paste the file path in the Default value field. Press F2 to insert the value of the filepath.</p> <ul style="list-style-type: none"> Variable: Enables you to specify the file variable that contains the location of the attachment. <ul style="list-style-type: none"> Specify the path that you want to attach in the Value field. Click Add to attach multiple files.
Variable	<p>Enables you to specify the list of file objects that contain the location of the attachments.</p> <p>Create a new variable of type List with subtype File, and add the filepath in the Default value field (optional). You can choose the file from the Desktop or Control room.</p>

6. Optional: Select the **Raise error if attachments are missing (desktop only)** check box to verify that you have attached a file and the attached file exists.

Option	Result
The Raise error if attachments are missing (desktop only) check box is selected	If a file is not attached, the email is not sent and the bot encounters an error.
The Raise error if attachments are missing (desktop only) check box is not selected	The email is sent even if a file is not attached.

7. Select the format that you want to use from the following options:

Option	Description
Plain text	Use regular text in your email body, with no formatting effects, such as bold, italic, or underline, or special layout options.

Option	Description
HTML code	Use HTML script in your mail body when you want your content to be displayed in a certain layout every time. You can also include interactive elements, such as links.
HTML design editor	Use this option to create and customize your email layout and body. Use the editor toolbar to make various changes to your text, such as applying bold, italic, and other formatting effects, inserting links, and changing the font and size of the text. You can copy the content from the design editor and paste it to other windows.

8. Enter the content you want to send along with the email in the **Message** field.
The email will be appended to the message you have specified.
9. Optional: Select the **Include Go Green message at the end of the email** check box.
The Go Green message appends the following text to the bottom of the email body: *Please consider the environment before printing. Let's Go Green!*
10. Select the **Email server, EWS** or **Outlook** option from the **Send email via** list to specify whether to send the emails using Exchange Web Services (EWS), Microsoft Outlook, or a mail server.
 - If you selected the **Outlook** option, you do not have to provide any additional details.

Note: Multiple accounts are not supported on the local system. Set up only one account to access mails using bots.

- **Email server:** For information about the host and port to be used for the various mail servers, see [Email server settings](#) on page 2442.
 - **From address** Enter the email address.

Note: If the mail server does not support sending an email using an alias email address, use the same email ID in the **From address** as provided in the **Username** field while configuring the mail server.

- **Use secure connection (SSL/TLS):** Select **True** or **False**, or insert a Boolean variable.
- **Email server host:** Enter the host you want to connect.

Note: If you use the host Outlook.office365.com, there is a limit of 30 messages sent per minute and 10,000 recipients per day.

- **Email server port:** Enter the port you want to use to establish the connection.
- **My server requires authentication:** Select **True** or **False**, or insert a Boolean variable.
- **Authentication mode:** Select the authentication type:
 - **Basic**
 - **OAuth2 – Authorization code with PKCE**

Depending on the authentication mode that you selected, you must specify the details in the following fields as applicable.

- **Username:** Enter the username that you want to use to access the mail server.
For example, john.smith@myCompanyName.com
- **Password:** Enter the password for the username you provided.
- For **Client ID**, **Tenant ID**, **Redirect URI**, and **Client secret** fields, enter the information that is provided for your account on your [Azure portal](#).
- **Email provider:** Select your email service provider from the drop-down list.
 - Outlook/Office365
If you select this option, then provide the **Tenant ID**.
 - Gmail

For **Username**, **Password**, **Tenant ID**, **Client ID**, and **Client secret** fields, choose from **Credential**, **Variable**, or **Insecure string** tab:

- **Credential:** Use a value available in the credential vault.
- **Variable:** Use a user-defined variable that stores the values.
- **Insecure string:** Manually enter a value.
- **EWS Server:**
 - **Exchange Version:** Select the version that your organization is using:
 - Exchange Server 2013
 - Exchange2010_SP2
 - Exchange2010_SP1
 - Exchange2010
 - Exchange2007_SP1
 - **Azure cloud:** Select the product that your organization is using:
 - **Azure Global:** For customers of Microsoft 365 Commercial version (login.microsoftonline.com)
 - **Azure US GCC High:** For customers of Microsoft 365 Government version (login.microsoftonline.us)
 - Optional: **Domain name:**
 - If you are an Office 365 customer and you leave this field blank, Automation Workspace uses smtp.office365.com to connect to the server.
 - If you are an Office 365 customer and you have entered a domain name in the **username** field, you must enter smtp.office365.com in this field.
 - If you are not an Office 365 customer, enter the domain name of your organization. Otherwise, Automation Workspace uses the domain name you provided in the **Username** field.
 - **Authentication mode:** Select the authentication types:

Note: From Automation 360 v.27 or later, the authorization type **OAuth2-Silent authentication mode** is renamed to **OAuth2-ROPC**, and the **OAuth2-Interactive authentication mode** is renamed to **OAuth2-Implicit**.

- **Basic**
- **OAuth2-ROPC**

- **OAuth2-Implicit**
- **OAuth2 – Authorization code with PKCE**
- **OAuth2 – Client credentials**

Depending on the authentication mode that you selected, you must specify the details in the following fields as applicable.

- **Username:** Enter the username that you want to use to access the mail server.
For example, `john.smith@myCompanyName.com`
- **Password:** Enter the password for the username you provided.
- For **Client ID**, **Tenant ID**, **Redirect URI**, and **Client secret** fields, enter the information that is provided for your account on your [Azure portal](#).
- **Test connection:** Click **Test connection** to sign in to your account, accept the permissions requested to authenticate, and establish a connection with the server.

Note: When you perform desktop operation and click **Test connection** to sign in to your account, then add this redirect URI: `https://outlook.office365.com`.

For **Username**, **Password**, **Tenant ID**, **Client ID**, and **Client secret** fields, choose from **Credential**, **Variable**, or **Insecure string** tab:

- **Credential:** Use a value available in the credential vault.
- **Variable:** Use a user-defined variable that stores the values.
- **Insecure string:** Manually enter a value.

11. Click **Save**.

Using the For each mail in mail box iterator

You must use certain **Email** actions within a **Loop** action. Use the **For each mail in mail box** iterator to repeat a set of actions on all the emails within the specific parameters.

First, connect to the email server. [Using Connect action for Email](#) on page 2437

When you establish a connection with Microsoft Outlook, email messages are processed from the shared mailbox. Ensure that you have set up the shared mailbox in your Outlook application.

Note: This feature is supported only for Outlook.

You must use the following Email actions within a loop:

- **Change status**
- **Delete**
- **Save attachments**
- **Save email**

Emails are retrieved based on the sequence of the folders listed in the inbox field. Within each folder, emails are retrieved based on received date and time in the last in, first out (LIFO) order. Additionally, you can apply filters on the following fields:

- Types of emails: **All**, **Read**, and **Unread**

- Subject
- From a specific folder
- From specific sender
- Before, on, or after received date

To use an Email action within a loop, follow these steps:

1. Double-click or drag the **Loop** action from the **Loop** package in the **Actions** palette.
2. Select the **For each mail in mail box** option from the **Iterator** list.
3. In the **Session name** field, enter the name of the session that you used to connect to the email server in the **Connect** action.
4. In the **ALL**, **READ**, or **UNREAD** options, specify the type of email to retrieve from the email server.

Note: For an email server that uses the POP3 protocol, all emails are retrieved.

5. Optional: Specify the folder from which you want to retrieve the emails.
 - Microsoft Outlook and Yahoo: You can specify the name of the folder.
For example, `Inbox`, `Sent`, `Inbox/Sales`, `Inbox/IT` and so on. The `Sales` and `IT` folders in this example are user-created folders and not available by default.
 - Gmail:
 - To retrieve emails from the default folders, you must use `[Gmail]/FOLDER`, except for the `Inbox` folder.
For example, `[Gmail]/Draft`, `[Gmail]/Important`, `[Gmail]/Trash`, and so on.
 - To retrieve emails from the folders you have created or the `Inbox` folder, you must specify the folder names as they are.
For example, if you have created folders called `Bank` and `Sports` in your Gmail, specify `Bank` and `Sports` without the `[Gmail]` prefix to retrieve emails from these folders.
6. Optional: In the **When subject contains** field, specify a value to retrieve emails containing the value you specified in their subject.
You can enter multiple text separated by semi-colon. When you specify multiple text separated by semi-colon, the emails are retrieved with any text or combination of text. For example, `[Subject]=[Automation Anywhere]`: The filter searches and retrieves emails where subject text includes `Automation` or `Automation Anywhere`.
To know about the behavior of the subject filter for package version 3.13.1-20220713-173156 and later using Microsoft Outlook server or Email server, see [How subject filter works when moving emails](#).
7. Optional: In the **From specific senders** field, specify the email addresses to retrieve the emails.
8. Optional: In the **When received date is on or after** list, select an option to retrieve specific emails on or after a certain date.
9. Optional: In the **When received date is on or before** list, select an option to retrieve specific emails on or before a certain date.

If you have specified values for Steps 6 through 9, the system retrieves only those emails that meet all the criteria. For example, if you specify `Bank` in Step 5, `Statement` in Step 6, and `abcbank@xyz.com` in Step 7, the system retrieves emails from the `Bank` folder that contain `Statement` in the subject and were received from the `abcbank@xyz.com` email address.

10. Choose one of the following options from **Use local timezone**

- True: The email received date and time is displayed in the local time zone.
- False: The email received date and time is displayed in the UTC time zone.
- Variable: Enter a Boolean variable.

11. Optional: In the **Assign the current value to variable** list, select or create a dictionary variable.

The dictionary variable stores the properties of each email. [Using dictionary variable for email properties](#) on page 2461.

12. Click **Save**.

Insert a **Message Box** action into the **Loop** container to print the subject of each email. Use the following message body, substituting the generic variable name for the one you used in Step 10: `$dictionaryVar{emailSubject}$`

Using dictionary variable for email properties

When you automate an email-related task, Automation Workspace retrieves various properties of an email and stores the values of these properties in a dictionary variable. These properties are stored in a dictionary variable when you use an email action within a loop action.

Some of the email properties that Automation Workspace retrieves are its subject, recipients, senders, message, and received date and time. The email properties are stored in a dictionary variable within the following dictionary keys:

Email property	Data type	Description
emailSubject	String	Retrieves the value of the email subject.
emailFrom	String	Retrieves the email ID which is received from. The from address is what your recipients will see.
emailTo	String	Retrieves the recipient's email ID.
emailCc	String	Retrieves the recipient mail id from the CC list.
emailBcc	String	Retrieves the recipient mail id from the BCC list.
emailMessage	String	Retrieves the text from the email body.
emailReceivedTime	String	Retrieves the time when the email was received.
emailReceivedDate	String	Retrieves the date when the email was received.
emailSentTime	String	Retrieves the time when the email was sent.

Email property	Data type	Description
emailSentDate	String	Retrieves the date when the email was sent.
emailNoOfAttachments	String	Retrieves the attachment count. If there are no attachments, the count displayed is 0.

Note: The email received and sent date and time are retrieved in the following format:

- Date: dd/MM/yyyy HH:mm:ss
Sample output: 22/09/2022 17:07:13
- Time: HH:mm:ss Z
Sample output: 17:07:13 +0900

The system automatically associates the properties of an email with the appropriate dictionary keys. You can use the values stored in these dictionary keys in another task, store them in a database, or for any other purpose. These keys are available in the system and you must use them as specified above. For example, if you have created a dictionary variable 'Test' and want to display the subject and sender of an email in a message prompt, you must enter `Test{emailSubject}` and `Test{emailFrom}` in the appropriate fields.

If you press F2 to use a variable in a field, you must select `Test` from the **Choose a variable** list and enter `emailSubject` in the **Dictionary key** field in the **Insert a variable** dialog box to store the subject of an email in that field. Similarly, you can enter `emailFrom` in the **Dictionary key** field to use the email address of the sender of an email in a field.

The dictionary key variable is required for all email-related tasks you automate from Microsoft Outlook and any mail server if you want to use the email properties. You can use the dictionary key variable for the following **Email** actions:

- **Change status**
- **Delete**
- **Forward**
- **Reply**
- **Save attachments**
- **Save email**

Note: The time required to save an email varies based on the size of the attachments available in that email.

How subject filter works when moving emails

In the **Move all** action and the **Loop** action in the Email package, learn how the subject filter works in order to move your emails from one folder to another in the email or Microsoft Outlook server.

You can use the keywords in the email subject field to filter emails. If keywords are added within quotes, the bot will look for an exact match of keywords in the subject field to filter and retrieve emails.

Outlook server

The following table explains how the subject filter works when the subject field contains single, multiple texts, or multiple subjects separated by semi-colon.

- Single text

Result	Example
With double quotes: Retrieves emails with the exact subject text and is case-sensitive.	Example: [Subject]=["Automation"]: The filter retrieves emails where the subject text includes "Automation" as an exact word.
Without double quotes: Retrieves emails that have the similar text and is not case-sensitive.	Example: [Subject]=[Automation]: The filter searches and retrieves emails where the subject text includes Automation.

- Multiple text

Result	Example
With double quotes: Retrieves emails with the exact subject text and is case-sensitive.	Example: [Subject]=["Automation Anywhere"]: The filter retrieves emails where subject text includes "Automation Anywhere" as an exact phrase.
Without double quotes: Retrieve emails with any text or combination of text and is not case-sensitive.	Example: [Subject]=[Automation Anywhere]: The filter searches and retrieves emails where subject text includes Automation or Automation Anywhere.

- Multiple subjects separated by semi-colon

Result	Example
With double quotes:Retrieves emails with the complete subject line that is an exact match including the semicolon and double quotation marks.	Example: [Subject 1] =["Delivery Failure"];[Subject 2] =["Mail server not found"], separated by a semicolon. The filter retrieves emails with the subject line as one string that is an exact match with the semicolon, such as "Delivery Failure ; Mail server not found".
Without double quotes: Retrieve emails with the complete subject line including the semicolon.	Example: [Subject 1]= ["Delivery Failure"];[Subject 2]= ["Mail server not found"], separated by a semicolon. The filter retrieves emails with the subject line that includes text as one string with the semicolon but is not an exact match, such as: Delivery Failure ; Mail server not found or delivery failure ; mail server not found.
Some with double quotes and some without double quotes: Retrieve emails with the complete subject line that is an exact match including the semicolon.	Example: [Subject 1]= [Delivery Failure];[Subject 2]= ["Mail server not found"], separated by a semicolon. The filter retrieves emails with the subject line as one string that is an exact match with the semicolon, such as: Delivery Failure ; Mail server not found.

Email server

The following table explains how the subject filter works when the subject field contains single, multiple texts, or multiple subjects separated by semi-colon.

- Single text

Result	Example
With double quotes: Retrieves emails with the exact subject text and is case-sensitive.	Example: [Subject]=["Automation"]: The filter retrieves emails where the subject text includes "Automation" as an exact word.
Without double quotes: Retrieves emails that have the similar text and is not case-sensitive.	Example: [Subject]=[Automation]: The filter searches and retrieves emails where the subject text includes Automation.

- Multiple text

Result	Example
With double quotes: Retrieves emails with the exact subject text and is case-sensitive.	Example: [Subject]=["Automation Anywhere"]: The filter retrieves emails where subject text includes "Automation Anywhere" as an exact phrase.
Without double quotes: Retrieve emails with any text or combination of text and is not case-sensitive.	Example: [Subject]=[Automation Anywhere]: The filter searches and retrieves emails where subject text includes Automation Or Automation Anywhere.

- Multiple subjects separated by semi-colon

Result	Example
With double quotes:Retrieve emails for each subject that is an exact match and is case-sensitive.	Example: [Subject 1] =["Delivery Failure"];[Subject 2] =["Mail server not found"] Individual subjects separated by a semicolon with an exact match are searched. The filter retrieves emails with the subject line "Delivery Failure" and/or "Mail server not found".
Without double quotes: Retrieve emails for each subject and is not case-sensitive.	Example: [Subject 1]= [Delivery Failure];[Subject 2]= [Mail server not found] The filter retrieves emails that include the subject line with text as Delivery Failure or Mail server not found.
Some with double quotes and some without double quotes: Retrieve emails for each subject. Subjects within double quotation marks are an exact match. Subjects without double quotes are not case-sensitive.	Example: [Subject 1]= [Delivery Failure];[Subject 2] = ["Mail server not found"] <ul style="list-style-type: none"> For Subject 1, the filter searches and retrieves emails that include the text in the subject line. For Subject 2, the filter searches and retrieve emails with the exact text in the subject line.

EWS Server

The following table explains how the subject filter works when the subject field contains single or multiple texts with, or without, double quotes.

Email Subject										
Search with keyword:	move email	move email (Include space)	Move email	"move email"	"Move email"	" move email" (I space)	" Move email" (I space)	move email test	move email	email
move email	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	-	-
move email	-	-	-	-	-	Yes	Yes	-	-	-
Move email	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	-	-
"move email"	Yes	Yes	-	Yes	-	Yes	-	Yes	-	-
"Move email"	-	-	Yes	-	Yes	-	Yes	-	-	-
" move email"	-	-	-	-	-	Yes	-	-	-	-
" Move email"	-	-	-	-	-	-	Yes	-	-	-
move email test	-	-	-	-	-	-	-	Yes	-	-
move email	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	-
email	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	-	Yes
email"	-	-	-	Yes	Yes	Yes	Yes	-	-	-
"move email"	-	-	-	Yes	Yes	-	-	-	-	-

Note:

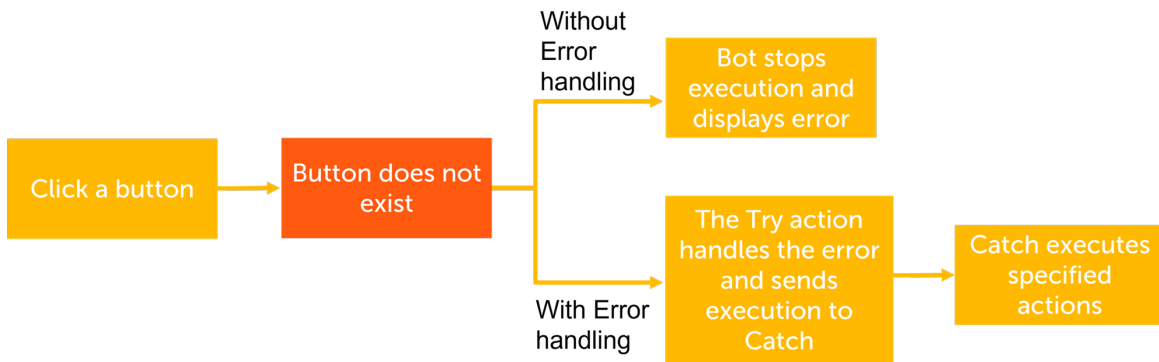

- When you search with keywords such as `move email`, `Move email`, or `move`, the bot will look for the keywords in the **Subject** field to filter and retrieve emails.
- When you search with keywords inside a pair of double quotation marks in the **Subject** field such as `"Move email"`, `"Move email"`, `"move`, or `email"`, the bot will look for an exact match of keywords and is case-sensitive to filter and retrieve emails.

Error handler package

If a bot encounters an error due to an abnormal condition or exceptions during execution, the normal execution of the bot is hindered, and the bot fails to complete the task. The Error handler package contains actions that enable you to easily handle exceptions a bot encounters and transfers control to the other actions within that bot.

The actions in the package enable you to separate the actions you want to use to perform a task from the actions you want to use to handle an exception. Handling exceptions ensures that a bot completes a task when it encounters an error and defines actions when an error occurs. Exceptions can be handled by the parent bot or any of the available child bots. However, the bot execution will fail if there is no error handling available in either the parent or child bots.

The following image illustrates how bot execution works when you use and do not use error handling in your task.

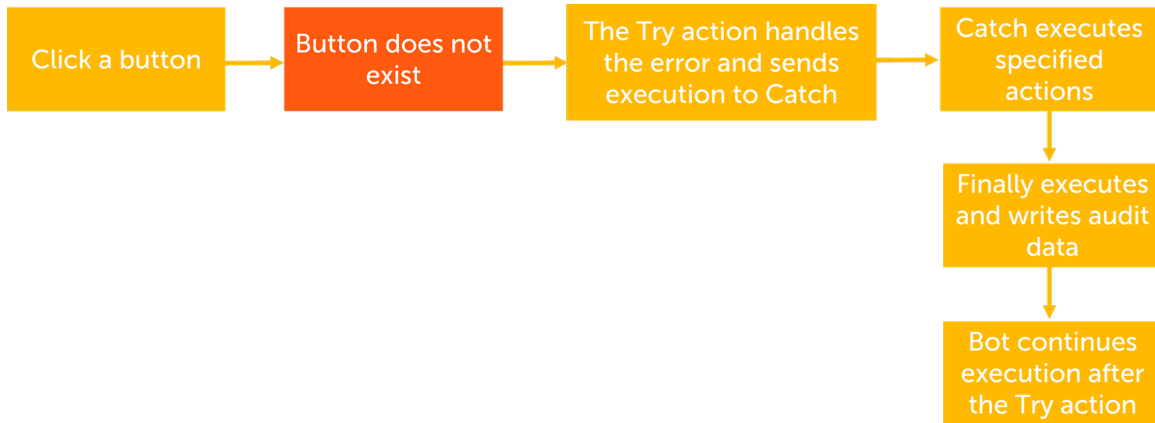

Actions in the Error handler package

The Error handler package includes the following actions:

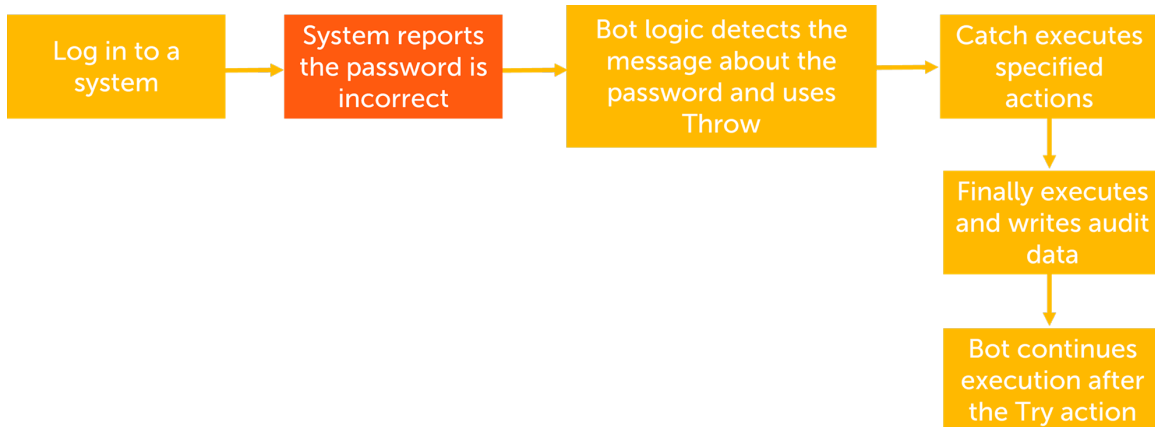

Action	Description
Try	See Try action in Error handler on page 2469.
Catch	See Catch action in Error handler on page 2470.
Finally	See Finally action in Error handler on page 2471.
Throw	See Throw action in Error handler on page 2471.

How Error handler handles exceptions

The following image illustrates the flow of actions of the Error handler package when an external error is encountered during bot execution.

The following image illustrates the flow of actions of the Error handler package when an internal error is encountered during bot execution.

Example: Using the actions in the Error handler package

For example, if you have a bot that reads data from a Microsoft Excel file and stores it in a database. The bot might encounter an error if the required file is not available or while updating a table in the database. Use the following methods to handle the errors:

- Exception 1:
 - The Microsoft Excel spreadsheet from which you want to extract data is not available.
 - How to handle: Use another file that contains the same data.
- Exception 2:
 - The table that you want to use to store the data is not available in the database.
 - How to handle: Display a message that the required table is not available.

Based on this example, perform the following to handle the mentioned exceptions:

1. Place all the actions that are for reading the data from the Microsoft Excel spreadsheet and storing the extracted data into a table in the database within the **Try** action.
2. Place the actions to run for the following exceptions within the **Catch** action:

- a) Exception 1: Place the actions to use the alternate file that contains the same data.
 - b) Exception 2: Place the **Message box** action to display a relevant message.
3. Place the **Database > Disconnect** action to terminate the connection with the database within the **Finally** action, which occurs regardless of the **Try** outcome.

Related reference

[Error handler package updates](#) on page 842

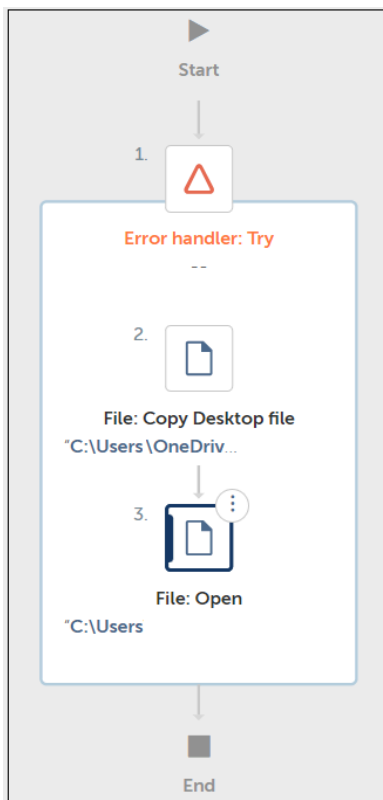

Review the updates in released versions of the Error handler package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Try action in Error handler

The **Try** action in the Error handler package can be used to add the other actions for the bot.

Settings

By including the **Catch** action, an error or exception message is displayed when any of the actions that you have added in the **Try** action encounter an error. If the bot does not encounter any errors, execution continues to the **Finally** action if it exists. Consider the following example of using the **Try** action where you want to copy a file from one location to another, and open it. The following image shows the **Copy** and **Open** actions in the **Try** action:

In the above scenario, an error can occur for the following:

- If the file that you are trying to copy does not exist.
- If you have specified a wrong filepath in the **Copy** action and the file was copied elsewhere.

In either case, the bot will be executed. However, if you have the **Catch** action, an error message can be displayed.

Catch action in Error handler

Use the **Catch** action in the Error handler package to take control of the bot execution when an error occurs within the **Try** action.

You can assign values for the error description and the line number to variables within the **Catch** action. You can add additional actions within a **Catch** block to handle errors. These actions can include an Email **Send** action (sending an email about the error), a **Log to file** action (logging the error condition to a file), or a Screen **Capture window** to capture a screenshot of the window or application when the error occurs.

You can use the **Try** and **Catch** actions multiple times in a bot. This enables you to run a different set of actions based on any exceptions that might be encountered.

Consider a scenario where you want to copy a file from one location to another, open this file to view it, and then log any errors that are encountered during this process. You can use the **Copy** and **Open** actions from the **File** package in the **Try** block. You can then use the **Log text to file** action in the **Catch** block to capture any errors encountered during the bot run. The following

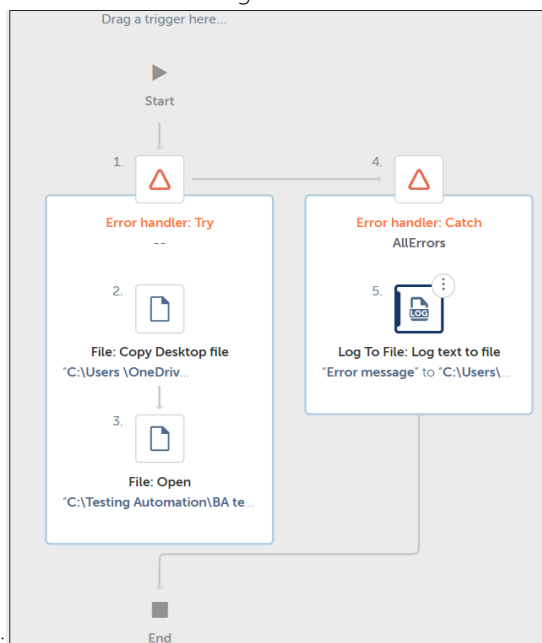

image shows the flow for this sample scenario:

Settings

- Use the **Exception** drop-down to select **Error handler**.
The **Error handler** applies to all the exceptions or errors that are encountered in the **Catch** block. You can then use the **Assign exception message to** field to provide a variable to store the exception message.
- Select the **On error, continue with next action** check box.

When you select the **On error, continue with next action** check box, even if there is an error from an action in the **Catch** block, no exception is thrown and the bot continues to the next action.

Note: This enhancement applies to all the nested actions in the **Catch** block. For example, you add a nested **Catch** block inside an existing (main) **Catch** block. If you select the **On error, continue with next action** check box in the main **Catch** block, errors from any of the actions in the nested **Catch** block are also handled (ignored).

- (Optional) Use the **Assign exception message to** field to select an existing variable.

Use this field to provide a variable to store the exception if any of the actions encounter an error. For example, if you have used the **File > Open** action and it encountered an error, the **Assign exception message to** can be used to review the error message. The error message must be stored in a variable that you reference when logging the error so that you can have some insight into what has caused the issue. If there are no existing variables, click the **Create variable** icon to create one.

- (Optional) Use the **Assign the line number to** field to select an existing variable.

Use this field to provide a number variable to hold the exact line number where an error occurred in the **Try** action. Like the exception error message, the line number is also stored in a log file for troubleshooting and further investigation. You can use the line number in either the **List** or **Dual** view of the bot editor to review the actions.

Note: The code inside the **Catch** action is only executed if there is an error. If everything in the **Try** block runs successfully the **Catch** action will not be executed.

Finally action in Error handler

Use the **Finally** action in the Error handler package to enable you to execute actions after **Try** and **Catch**, regardless of whether an exception occurs or not.

Settings

The **Finally** action is most useful in logging audit information or any action that must follow the end of the **Try** and **Catch** actions.

Throw action in Error handler

Use the **Throw** action in the Error handler package to create an error condition, which will immediately shift the bot execution to the **Catch** action.

If a logical error occurs in the **Try** action, you can use the **Throw** action to create an error condition, which will immediately shift the bot execution to the **Catch** action. You can edit the **Throw** action properties to set the error message to be sent to the **Catch** action. Outside of a **Try** action, the **Throw** action causes a standard error dialog box to be displayed, requiring a user to manually click the **Close** button to dismiss it.

Consider a scenario where your bot is reading data from a spreadsheet that contains employee IDs in column A. If there is an empty row or an invalid employee ID, the **Throw** action will trigger the **Catch** block to record the error. The **Try**, **Catch**, and **Finally** actions can be used within a

loop. This ensures that capturing such errors does not have to necessarily stop the processing of the entire automation. Instead, just stop the processing of that one data record and log the error.

Settings

- (Optional) Use the **Please enter exception message** field to enter a message that must be displayed when the bot encounters an error.

You can also click the **Insert a variable** icon to select an existing variable.

- Use the **Exception** drop-down to select a botexception.

Excel basic package

The Excel basic package contains actions that enable you to automate many of the repetitive tasks in XLSX workbooks. You use these actions when Microsoft Excel is not available on the device that you want to use to automate Microsoft Excel-related tasks.

Note: The XLS and CSV formats are not supported and you cannot set a value in the XFD column of a spreadsheet.

Important: If you use different versions of the Excel basic package in a parent bot and a child bot, the capability to share a session across bots is currently not supported. To share a session across parent and child bots, ensure that you use the same version of the package in both the parent and child bots.

Important: When you use Microsoft Excel Version 2208 and a bot tries to open an unprotected macro, a security warning is displayed indicating that the macros are blocked as they are not from a trusted source.

See [Macros from the internet will be blocked by default in Office](#) for more details.

Choosing the Excel package in Automation 360

Automation 360 includes packages to support three types of Microsoft Excel usage. For optimal results, use the package that corresponds to the type of Excel that is available on the device you are running bots on.

- No Excel installed: If you do not have Microsoft Excel installed on the device on which you are running bots to automate Excel-related processes, use the Excel basic package.
- Desktop Excel installed: If you have a desktop version of Microsoft Excel installed on your computer, use the Excel advanced package in your bots.
- Online Microsoft 365 Excel only: If you are using Microsoft Excel 365 on a web browser, use the Microsoft 365 Excel package for automating tasks related to Excel.

Recommendation: For any bot automation use case that cannot be fulfilled by the Excel basic package, we recommend that you use the Excel advanced package. When you use that Excel basic package, you might experience limitations because of the Apache POI API that the package

uses. Because of this, the Excel basic package has limited capability when compared to the Excel advanced package that uses the MS API.

To learn more, search for the Automating Excel Workbooks course in [Automation Anywhere University: RPA Training and Certification \(A-People login required\)](#).

Before you start

Perform the following actions within the Excel basic package as part of using the set of available actions:

1. Open the Microsoft Excel spreadsheet that you want to read data from using the **Open** action.

Note: The Excel basic package supports files that are a maximum size of 30 MB.

You must associate the details of the file you want to use with a session name, and use the session name in the other actions in the Excel basic package, so that you do not have to provide the details of the file in those actions again.

2. Use the different actions available in the Excel basic package to automate the Microsoft Excel-related tasks.
3. After you have automated all the Microsoft Excel-related tasks, close the spreadsheet using the **Close** action.

Actions in the Excel basic package

The Excel basic package includes the following actions:

Action	Description
Close	See Close action on page 2474.
Delete cells	See Delete cells action on page 2474.
Find	See Using Find action in Excel on page 2501.
Get cell address	See Get cell address action on page 2476.
Get column name	See Get column name action on page 2476.
Get multiple cells	See Get multiple cells action on page 2475.
Get row number	See Get row number action on page 2476.
Get single cell	See Get single cell action on page 2475.

Action	Description
Go to cell	. See Go to cell action on page 2477.
Open	See Using the Open action .
Replace	See Using the Replace action on page 2507.
Save workbook	See Save workbook action on page 2478.
Set cell	See Set cell action on page 2478.
Switch to sheet	See Switch to sheet action on page 2479.

[Excel basic package updates](#) on page 844

Review the updates in released versions of the Excel basic package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Close action

The Close action in the Excel basic package enables you to close an excel spreadsheet and **Save changes** when closing the file.

Settings

Closes the current workbook and provides an option to **Save changes** when closing the file. Enter the name of the session used to open the workbook with the **Open** .

Note: This action terminates the process for the session.

Delete cells action

The Delete cells action in the Excel basic package enables you to delete the **Active cell** or a **Specific cell** from the current worksheet.

Settings

- Select the **Active cell** or **Specific cell** option to specify whether to retrieve the values from the active cell or a specific cell.
- Select the **Shift cells left** or **Shift cells up** option to specify whether to shift the cell one position to the left or up after the cell is deleted.
- Select the **Entire row** or **Entire column** option to specify whether to delete the entire row or column of the cell.
- Enter the name of the session used to open the workbook with the **Open** .

Get multiple cells action

The Get multiple cells action in the Excel basic package enables you to retrieve the values from cells in a Microsoft Excel spreadsheet and stores them in a table variable.

Settings

This action retrieves cell values as string data types. It supports Excel cell formats, including Number, Percentage, Currency, Scientific, and Date. For example, a value from a cell of Currency formatting retains the currency symbol when passed to a table or record variable.

Note: You must convert the values to perform non-string operations.

- Select any of the following options from the **Loop through** field:

Option	Action
All rows:	Enables you to retrieve the values from all the rows.
Specific row:	Enables you to retrieve the values from the row you have specified in the From row and to row fields.
Cell range:	Enables you to retrieve the values from the range of cells you have specified in the From cell and to cell field.

- Enter the name of the session used to open the workbook with the **Open** .
- In the **Get value to the variable (optional)** field, create or insert an existing string variable.

Get single cell action

The Get single cell action in the Excel basic package enables you to retrieve the values from a single cell in a Microsoft Excel spreadsheet and stores them in a string variable .

Settings

This retrieves cell values as string data types. It supports Excel cell formats, including Number, Percentage, Currency, Scientific, and Date. For example, a value from a cell of Currency formatting retains the currency symbol when passed to a table or record variable.

Note: You must convert the values to perform non-string operations.

- Select the **Active cell** or **Specific cell** option to specify whether to retrieve the values from the active cell or a specific cell.
- Enter the name of the session used to open the workbook with the **Open** .
- In the **Store cell contents to** field, create or insert an existing string variable.

You can use the output value to

[Example of using a conditional statement](#) on page 3078

Get cell address action

The Get cell address action in the Excel basic package enables you to retrieve the location of the active cell and stores it to a string variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- In the **Save the active cell address in local variable** field, create or insert an existing string variable.

Get column name action

The Get column name action in the Excel basic package enables you to retrieve the letter value of the column of the active or specific cell and store it to a string variable.

Settings

- Select the **Active cell** or **Specific cell** option to specify whether to retrieve the column name from the active cell or a specific cell.
- Enter the name of the session used to open the workbook with the **Open** .
- In the **Save the column name into local variable** field, create or insert an existing string variable.

Get row number action

The Get row number action in the Excel basic package enables you to retrieve the row number of the active or specific cell and stores it to a string variable.

Settings

- Select the **Active cell** or **Specific cell** option to specify whether to retrieve the row number from the active cell or a specific cell.
- Enter the name of the session used to open the workbook with the **Open** .
- In the **Save the row number into local variable** field, create or insert an existing string variable.

Go to cell action

The Go to cell action in the Excel basic package enables you to select a specific cell in a Microsoft Excel spreadsheet.

Settings

- Select the **Active cell** or **Specific cell** option to specify which cell to select.
- Enter the name of the session used to open the workbook with the **Open** .

Using the Open action for Excel basic

Use the **Open** action to open Microsoft Excel spreadsheet in read-only mode or read-write mode, use a password to open the spreadsheet, and so on.

To open a Microsoft Excel spreadsheet, do the following:

1. Double-click or drag the **Open** action from the **Excel basic** package in the **Actions** palette.
2. Select from where you want to open the Microsoft Excel spreadsheet:

Note: The Excel basic package supports files that are a maximum size of 30 MB.

- **Control Room file:** Enables you to open a file from the Control Room.

Note: When you open an excel file from the Control Room and make changes in the file, the updated file does not save in the Control Room This action is supported only for Excel files opened from the desktop.

- **Desktop file:** Enables you to open a file from the device. This field also accepts the file path input as a string variable or global value.
 - **Variable:** Enables you to open a file by specifying a file variable.
3. Select the **Sheet contains a header** check box if the Microsoft Excel spreadsheet contains a header row.
 4. Select the **Specific sheet name** option and specify the name of the sheet to activate when the Microsoft Excel spreadsheet opens.
 5. Select **Read-only mode** or **Read-write mode** to open the Microsoft Excel spreadsheet in read-only or edit mode, respectively.
 6. Select the **Password is required** check box if a password is required to open the Microsoft Excel spreadsheet.
 7. Select any of the following tabs to create an Excel session:
 - **Local session:** Specify a session name that can be used only in the current bot.
 - **Global session:** Specify a session name that can be used across multiple bots, such as parent bots, child bots, and other child bots of the parent bots .

You can also use the **Global session** option to loop through each row in an Excel advanced worksheet.

Note: You can open an Excel worksheet by using the **Global session** option and use it across multiple bots without having to share the session by using the **Set session variable** action.

You can also close the session from the child bot when you are using the **Global session** option and sharing the session across child bots.

Important: If you close the session from the child bot and run the parent bot, then in the parent bot, the actions that come after the child bot are not run, and the bot fails with an error because the session has already been closed from the child bot.

- **Variable:** Specify a session variable that can be used to share that session with other child bots.
-

Note: When you use more than one workbook to automate an operation, you must use different session names for each workbook. If you want to use the same session name to automate all the workbooks, you must first close the session of one workbook before using the same session name for another workbook.

8. Enter the name of the session in the **Session name** field.
9. Click **Save**.

Save workbook action

The **Save workbook** action in the Excel basic package enables you to save a Microsoft Excel spreadsheet to a specified location.

Settings

- Double-click or drag the **Save workbook** action from the Excel basic package in the **Actions** palette.
- In the **Session name** field, click one of the following tabs:
 - **Session name** - Enter the name of the session used to open the workbook with the **Open** . See, [Using the Open action for Excel basic](#) on page 2477.
 - **Variable** - Enter the basic session variable that you have added in the **Set session variable** action or from the parent bot.

Set cell action

The Set cell action in the Excel basic package enables you to set the value you have specified in a cell in a Microsoft Excel spreadsheet.

Settings

- Select the **Active cell** or **Specific cell** option to specify whether to set the value in the active cell or a specific cell.

- Enter the cell value to set in the **Value to set** field.
- Enter the name of the session or variable used to open the workbook with the **Open** action.

Switch to sheet action

The Switch to sheet action in the Excel basic package enables you to activate a specific worksheet.

Settings

- Select to activate the worksheet by the **Index** value or worksheet **Name**.
 - The index is the numeric value assigned to the worksheet.
- Enter the name of the session used to open the workbook with the **Open** .

Excel advanced package

The Excel advanced package contains actions that enable you to automate many of the repetitive tasks when working with Microsoft Excel spreadsheets.

You can automate tasks related to the workbook, worksheet, rows, columns, and cell operations. You can use these actions when Microsoft Excel is installed on the device that you want to use to automate the Microsoft Excel-related tasks.

Note:

- The Excel file that you use from the Control Room is applicable only for the current bot session. If you modify the file during bot execution, the updated file cannot be uploaded back to the Control Room
- You need not install the Microsoft Access Database Engine as an additional component in your system to use Excel as Database if you are using any of the following office versions:
 - Microsoft 365 Apps for Enterprise
 - Office 2016, 2019, or 2021 (Consumer Version 2009 or later)

However, if you have both Microsoft 365 Apps and the Microsoft Access Database Engine are installed on your system, then you can uninstall the Microsoft Access Database Engine and repair Microsoft 365 Apps.

Microsoft recommends that you do not install the Microsoft Access Database Engine driver separately because both the Microsoft Access Database Engine 2016 and Microsoft 365 Apps use the same major version identifier (16.0). To learn more about the Microsoft Access Database Engine driver installation requirement, see [Unable to use the Access ODBC or OLEDB provider](#)

Important: When you use Microsoft Excel Version 2208 and a bot tries to open an unprotected macro, a security warning is displayed indicating that the macros are blocked as they are not from a trusted source.

See [Macros from the internet will be blocked by default in Office](#) for more details.

Important: If you use different versions of the Excel advanced package in a parent bot and a child bot, the capability to share a session across bots is currently not supported. To share a session across parent and child bots, ensure that you use the same version of the package in both the parent and child bots.

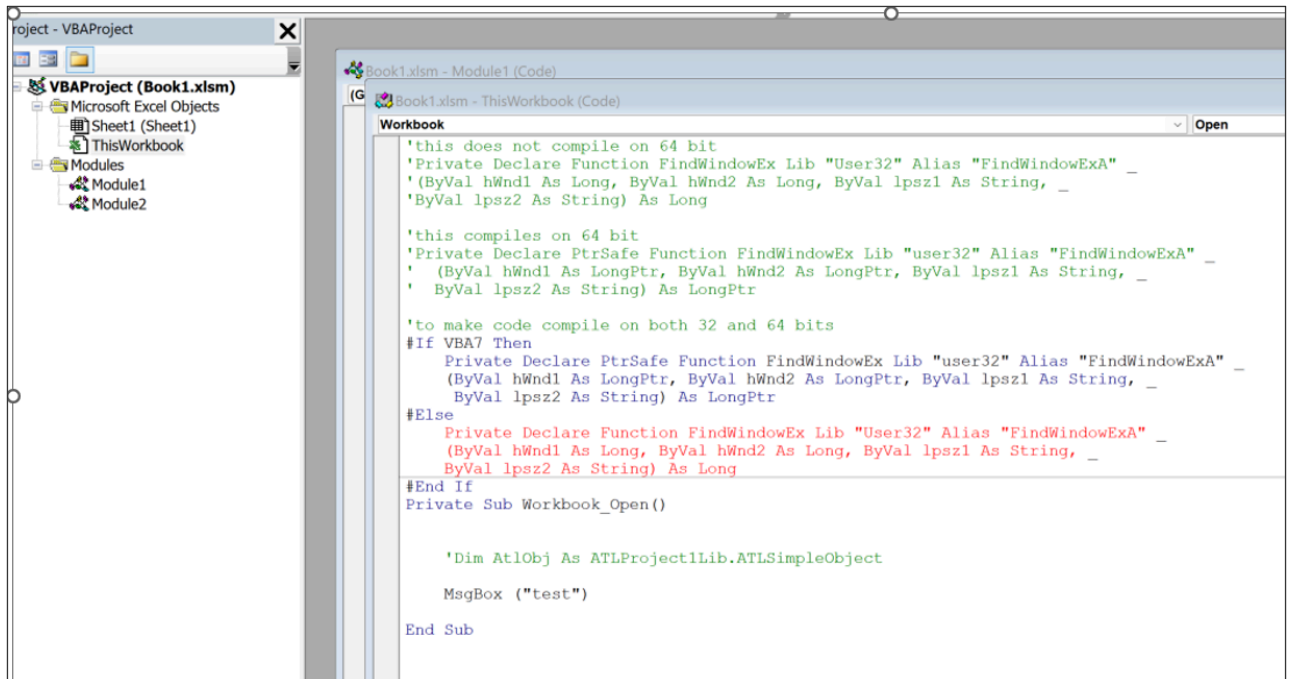

Actions in the Excel advanced package support Microsoft Office 2016 through Microsoft Office 2019, Microsoft 365, and the following file formats:

- .xls
- .xlsx
- .xlsb
- .xml
- .xlsm
- .txt
- .ods
- .htm
- .html
- .mht
- .mhtml
- .slk
- .pdf

Important:

- For files with .ods extension, unless you specify the sheet name in the **Specify sheet name** field of the **Open** action, the action always opens the .ods file with the first sheet as active, by default. If the sheet name contains a space character, after you save and close the Excel sheet, the space character is displayed as underscore.
- Files with the .htm, .html, .mht, and .mhtml extensions cannot be converted into PDF.
- Files with the .slk and .pdf extensions contain only a single sheet. The sheet cannot be renamed. If you rename the sheet and save the Excel sheet, the sheet does not retain the new name.
- Files with .htm, .html, .mht, .mhtml, .slk, and .pdf extensions cannot retain passwords.
- You cannot run a macro in files with the .pdf extension.
- Note: Macro-enabled Excel applications with VBA using 32-bit and 64-bit code are not supported. If you encounter a `Compile error in hidden module` error message when

running a macro, then see the following image to add the VBA code manually in the Excel file

You can also use some of the actions with the .csv format. See [CSV operations in Excel advanced](#) on page 2512.

See [Example of migrating data from Excel to a database](#) on page 3088.

Choosing the Excel package in Automation 360

Automation 360 includes packages to support three types of Microsoft Excel usage. For optimal results, use the package that corresponds to the type of Excel that is available on the device you are running bots on.

- No Excel installed: If you do not have Microsoft Excel installed on the device on which you are running bots to automate Excel-related processes, use the Excel basic package.
- Desktop Excel installed: If you have a desktop version of Microsoft Excel installed on your computer, use the Excel advanced package in your bots.
- Online Microsoft 365 Excel only: If you are using Microsoft Excel 365 on a web browser, use the Microsoft 365 Excel package for automating tasks related to Excel.

Before you start

Perform the following actions within the Excel advanced package as part of using the set of available actions:

1. Open the Microsoft Excel spreadsheet that you want to use to automate the Microsoft Excel-related tasks. Use the **Open** action to open the spreadsheet. See [Using the Open action for Excel advanced](#) on page 2485.

Note: For files containing large data sets, use actions from the Database package to automate create, read, and update operations. See [Using Connect action for database](#) on page 2382.

2. Use the different actions available in the Excel advanced package to automate the Microsoft Excel-related tasks.
3. After you have automated all the Microsoft Excel-related tasks, close the spreadsheet using the **Close** action.

Actions in the Excel advanced package

The actions in the Excel advanced package enable you to perform the following operations:

Action	Description
Cell operations	Perform operations such as extracting data from cells, deleting values from a cell, moving a cursor to a specific cell, and finding and replacing content. See Cell operations in Excel advanced on page 2500.
Row and column operations	Perform operations such as inserting new rows and columns, and hiding and unhiding rows and columns. See Row and column operations in Excel advanced on page 2495.
Table operations	Perform operations such as sorting and filtering data in a table, inserting and deleting columns, and getting the table range. See Table operations in Excel advanced on page 2509.
Workbook operations	Perform operations such as opening a workbook, appending data, protecting and unprotecting a workbook, and converting a Microsoft Excel workbook to a PDF file. See Workbook operations in Excel advanced on page 2483.
Worksheet operations	Perform operations such as creating and deleting a worksheet, appending data, and hiding and unhiding a worksheet. See Worksheet operations in Excel advanced on page 2488.

Example tasks:

- [Example of transferring data from CSV file to Excel worksheet](#) on page 3083
- [Example of using a conditional statement](#) on page 3078

Review the updates in released versions of the Excel advanced package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Workbook operations in Excel advanced

A workbook is a file that contains one or more worksheets. The **Excel advanced** package contains various actions that you can use to automate workbook-related tasks.

Workbook actions in the Excel advanced package

The **Excel advanced** package includes the following actions:

Action	Description
Append workbook	See Append workbook action on page 2483
Close	See Close action on page 2484
Convert excel to PDF	See Convert excel to PDF action on page 2484
Create workbook	See Create workbook action on page 2484
Open	See Using the Open action for Excel advanced on page 2485.
Protect workbook	See Protect workbook action on page 2487
Save workbook	See Save workbook action on page 2488
Unprotect workbook	See Unprotect workbook action on page 2488

Append workbook action

The Append workbook action in the Excel advanced package enables you to add all the worksheets from the specified workbook to the end of the currently open workbook.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Specify the workbook from which you want to append the worksheets in the **Append from workbook** field.

- If the workbook is protected, select the **Password is required** check box and enter the password in the **To open** field.
- In the **To open** field, provide your password with one of the following options:
 - **Credential**: Select a credential from the . [Credentials and credential variables in the Bot editor](#) on page 2254
 - **Variable**: Select a variable holding a credential data type value. [Your variables \(user-defined\)](#) on page 2241
 - **Insecure string**: Enter a value or select a variable.

Important: Values entered using this option are not encrypted.

Close action

The Close action in the Excel advanced package enables you to close the current workbook and provide an option to save changes when closing the file.

Settings

Enter the name of the session used to open the workbook with the **Open** .

Convert excel to PDF action

The Convert excel to PDF action of the Excel advanced package enables you to convert the entire workbook, specific worksheets in a workbook, or a CSV file to a PDF file.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Specify whether you want to convert the **Entire excel file**, **Active sheet**, or **Specific sheet** to a PDF file.
- Enter a name for the PDF file in the **Select PDF file name** field.
- Specify the location where you want to save the file in the **Select PDF storage location** field.

Create workbook action

The Create workbook action of the Excel advanced package enables you to create a Microsoft Excel workbook or a CSV file.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Specify the location where you want to save the workbook in the **File path** field.
- Specify the name of the worksheet in the **Sheet name** field.
- Specify the passwords to open and edit the workbook in the **Password to open** and **Password to edit** fields. Provide your password with one of the following options:

- **Credential:** Select a credential from the . [Credentials and credential variables in the Bot editor](#) on page 2254
- **Variable:** Select a variable holding a credential data type value. [Your variables \(user-defined\)](#) on page 2241
- **Insecure string:** Enter a value or select a variable.

Important: Values entered using this option are not encrypted.

- Select any of the following tabs to create an Excel session:
 - **Local session:** Specify a session name that can be used only in the current bot.
 - **Global session:** Specify a session name that can be used across multiple bots, such as parent bots, child bots, and other child bots of the parent bots.

You can also use the **Global session** option to loop through each row in an Excel advanced worksheet.

Note: You can open an Excel worksheet by using the **Global session** option and use it across multiple bots without having to share the session by using the **Set session variable** action.

You can also close the session from the child bot when you are using the **Global session** option and sharing the session across child bots.

Important: If you close the session from the child bot and run the parent bot, then in the parent bot, the actions that come after the child bot are not run, and the bot fails with an error because the session has already been closed from the child bot.

- **Variable:** Specify a session variable that can be used to share that session with other child bots.

Note: If the Microsoft sensitivity label feature is enabled for Microsoft 365 Excel application, see [Automation Anywhere interaction with Microsoft Labels \(A-people login required\)](#)

Using the Open action for Excel advanced

Use the **Open** action to open a Microsoft Excel spreadsheet or a CSV file. This action enables you to specify whether to open the spreadsheet in read-only mode or read-write mode, a password to open the spreadsheet, and so on.

When you use the Open action to open a macro-enabled Excel workbook of .x1sm format, the Auto_Open VBA procedure does not run automatically because the VBA procedure runs only when the Excel workbook is opened manually. This is a default behavior of Microsoft Excel. See [Behavior difference between Workbook_Open and Auto_Open procedure](#).

Note: You can use wildcard pattern based search to open an existing excel file that matches the search criteria. For example, if you have multiple files with similar names such as table1.xlsx, table2.xlsx, table3.xlsx, you can open the file by specifying the (*) wildcards in the file path as table*.xlsx to open the first file that matches the pattern.

1. Double-click or drag the **Open** action from the **Excel advanced** package in the **Actions** palette.
2. Select from where you want to open the Microsoft Excel spreadsheet:

- **File:** Select one of the following options to open a Microsoft Excel spreadsheet:
 - **Control Room file:** Enables you to open a file from the Control Room.
 - **Desktop file:** Enables you to open a file from the device. This field also accepts the file path input as a string variable or global value.

Note: In the **Desktop file** field, if you enter a file path or browse to a particular file from the system and if the file path is separated by the backslash (\) characters, when you save the bot, the backslash characters are changed to slash (/) characters because the bot uses slash characters to separate file paths. Your bots continue to run successfully even if the backslash characters are changed to slash characters during bot run.

- **Variable:** Enables you to open a file by specifying a file variable.
- **SharePoint:** In the **File path** field, enter the exact file path of the Excel spreadsheet on SharePoint. To copy the URL of the Excel spreadsheet from SharePoint, perform the following steps:
 - Open the Microsoft Excel spreadsheet on SharePoint.
 - In the Microsoft Excel spreadsheet, navigate to **File > Info**.
 - Click **Copy path**.
- 3. Select the **Sheet contains a header** check box if the Microsoft Excel spreadsheet contains a header row.
- 4. Select the **Specific sheet name** option and specify the name of the sheet to activate when the Microsoft Excel spreadsheet opens.
- 5. Select **Read-only mode** or **Read-write mode** to open the Microsoft Excel spreadsheet in read-only or edit mode respectively.
- 6. Select the **Password is required** check box if a password is required to open or edit the Microsoft Excel spreadsheet.
- 7. Select the **Load Add-ins** check box if you want to load the add-ins available in the Microsoft Excel spreadsheet.
- 8. Select the **Exclude hidden sheets** check box if you want to ignore the excel sheets that are hidden and do not want to perform any operation on those hidden sheets.
- 9. Select any of the following tabs to create an Excel session:
 - **Local session:** Specify a session name that can be used only in the current bot.
 - **Global session:** Specify a session name that can be used across multiple bots, such as parent bots, child bots, and other child bots of the parent bots .

You can also use the **Global session** option to loop through each row in an Excel advanced worksheet.

Note: You can open an Excel worksheet by using the **Global session** option and use it across multiple bots without having to share the session by using the **Set session variable** action.

You can also close the session from the child bot when you are using the **Global session** option and sharing the session across child bots.

Important: If you close the session from the child bot and run the parent bot, then in the parent bot, the actions that come after the child bot are not run, and the bot fails with an error because the session has already been closed from the child bot.

- **Variable:** Specify a session variable that can be used to share that session with other child bots.

Note: When you use more than one workbook to automate an operation, you must use different session names for each workbook. If you want to use the same session name to automate all the workbooks, you must first close the session of one workbook before using the same session name for another workbook.

10. Click Save.

Protect workbook action

The **Protect workbook** action of the Excel advanced package enables you to protect the workbook and its structure using a password.

Settings

- (Optional) Select the **Protect workbook** check box.
Protecting a workbook prevents other users from accessing the content without a password.
Use the **Enter password** field to select one of the following options to specify the password you want to use to protect the workbook:
 - **Credential:** To use a value available in the Credential Vault.
Click the **Pick** button to select a credential.
 - **Variable:** To use a value that is stored as a credential variable.
 - **Insecure string:** To manually specify the values.
(Optional) Click the **Insert a value** icon to insert an existing variable.
- (Optional) Select the **Protect workbook structure** check box.
Protecting the structure of a workbook prevents other users from adding, moving, deleting, hiding, and renaming worksheets within that workbook.
Use the **Enter password** field to select one of the following options to specify the password you want to use to protect the workbook:
 - **Credential:** To use a value available in the Credential Vault.
Click the **Pick** button to select a credential.
 - **Variable:** To use a value that is stored as a credential variable.
 - **Insecure string:** To manually specify the values.
(Optional) Click the **Insert a value** icon to insert an existing variable.
- Use the **Session name** field to select one of the following options:
 - **Session name:** Enter the name of the session used to open the workbook with the **Open ..**
 - **Variable:** Enter the session variable that you have used in the **Set session variable** action or in the parent bot.

Save workbook action

The Save workbook action of the Excel advanced package enables you to save the current workbook.

Settings

Enter the name of the session used to open the current workbook with the **Open** action.

Note: When you open an Excel file from the Control Room and make changes to the file, the updated file is not saved in the Control Room. This action is supported only for Excel files opened from the desktop.

Unprotect workbook action

The Unprotect workbook action of the Excel advanced package enables you to unprotect a workbook and its structure. Unprotecting a workbook removes the restriction applied on opening the workbook, and unprotecting the structure of a workbook removes the restriction applied on modifying the structure of the workbook. Unprotecting allows other users to open the workbook, add, move, delete, hide, and rename worksheets within the workbook.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Select the **Unprotect workbook** and **Unprotect workbook structure** check boxes and provide a password to unprotect the workbook structure.

Worksheet operations in Excel advanced

The **Excel advanced** package contains various actions that you can use to automate worksheet-related tasks.

Worksheet actions in the Excel advanced package

The **Excel advanced** package includes the following actions:

Action	Description
Access password protected worksheet	See Access password protected worksheet action on page 2489
Append worksheet	See Using Append worksheet action on page 2489.
Create worksheet	See Create worksheet action on page 2490
Delete worksheet	See Delete worksheet action on page 2490
Disable or enable real-time screen update	See Disable or enable real-time screen update action on page 2490

Action	Description
Get current worksheet name	See Get current worksheet name action on page 2491
Get worksheet as data table	See Get worksheet as data table action on page 2491
Get worksheet names	See Get worksheet names action on page 2492
Hide worksheet	See Hide worksheet action on page 2492
Password protect worksheet	See Password protect worksheet action on page 2492
Rename worksheet	See Rename worksheet action on page 2493
Retrieve sheets count	See Retrieve sheets count action on page 2493
Run macro	See Run macro action on page 2494
Switch to sheet	See Switch to sheet action on page 2494
Unhide all worksheets	See Unhide all worksheets action on page 2495
Unhide worksheet	See Unhide worksheet action on page 2495
Write from data table	See Write from data table action on page 2495

Access password protected worksheet action

The Access password protected worksheet action of the Excel advanced package enables you to access a password-protected worksheet in the current workbook.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Enter the password to access the worksheet.

Using Append worksheet action

Use the **Append worksheet** action to append a worksheet from another workbook to the current workbook.

Note: If the current workbook already has a worksheet with the same name, you must rename the worksheet being appended.

To append a worksheet, do the following:

1. Double-click or drag the **Append worksheet** action from the **Excel** node in the **Actions** palette.
2. Select an option to specify the location of the spreadsheet from which you want to append the worksheet:
 - From 'My bots': Enables you to open a Microsoft Excel spreadsheet from an existing bot.
 - **From local device**: Enables you to open a Microsoft Excel spreadsheet from a local device.

- **Select an existing file variable:** Enables you to open a Microsoft Excel spreadsheet using a file variable.
3. Select the **Password is required** option if the Microsoft Excel spreadsheet requires a password to open it.
 4. Optional: In the **User password** or **Owner password** field, enter a password to restrict access to the encrypted PDF file.
 - **User password:** Allow users to perform specific operations on the encrypted PDF file.
 - **Owner password:** Allow users to use a password to open the file.
 5. Select the **Enter worksheet name** or **Enter worksheet index** option to specify the name or number of the worksheet that you want to append.
 6. Enter the name of the session used to open the workbook with the **Open** .
 7. Click **Save**.

Create worksheet action

The Create worksheet action of the Excel advanced package enables you to create a worksheet in the current workbook.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Specify either an index number in the **Sheet by Index** field or a name in the **Sheet by Name** field for the worksheet. The index number is the number assigned to a worksheet. For example, if you want to perform an operation on the worksheet at the third position in the workbook, enter 3 in the field.

Delete worksheet action

The Delete worksheet action of the Excel advanced package enables you to delete a spreadsheet from the current workbook.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Specify either an index number in the **Sheet by Index** field or a name in the **Sheet by Name** field for the worksheet. The index number is the number assigned to a worksheet. For example, if you want to perform an operation on the worksheet at the third position in the workbook, enter 3 in the field.

Note: You can delete a worksheet only if the workbook contains more than one worksheet.

Disable or enable real-time screen update action

The Disable or enable real-time screen update action of the Excel advanced package enables you to disable the real-time screen update.

Settings

- Select the **Disable** option to disable real-time screen update when you perform actions in a Microsoft Excel worksheet with large data sets.
- Select the **Enable** option to re-enable real-time screen update for other, subsequent actions.
- Enclose the action that has performance issues within the **Disable or enable real-time screen update** action.

For example, if you are using the **Run macro** action to run a macro on a worksheet that has large data sets and if you are facing performance issues, use the **Disable or enable real-time screen update** action before the **Run macro** action and select the **Disable** option to disable real-time screen update for enhanced performance. Use the **Disable or enable real-time screen update** action again after the **Run macro** action and select the **Enable** option to re-enable real-time screen update for other, subsequent actions.

Important: We recommend using this action only if you face performance issues when you run actions with large data sets.

Get current worksheet name action

The Get current worksheet name action of the Excel advanced package enables you to get the name of the current worksheet and assign it to a string variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Select a string variable that you want to use to store the name of the worksheet from the **Assign the output to variable** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Get worksheet as data table action

The Get worksheet as data table action of the Excel advanced package enables you to get data from a worksheet and save it to a table variable.

Settings

- Specify either an index number in the **Sheet by Index** field or a name in the **Sheet by Name** field for the worksheet. The index number is the number assigned to a worksheet. For example, if you want to perform an operation on the worksheet at the third position in the workbook, enter 3 in the field.
- Choose from the **Read** option to read either the visible text or value of the cell.

For example, if the cell has 70% as cell content, **Read cell value** option will read the value as 70 ignoring the % format whereas **Read visible text** option will read the content as 70%.

Recommendation: Use option **Read cell value** as reading value from a cell gives better performance than reading a visible text.

- Enter the name of the session used to open the workbook with the **Open** .
- Select a table variable that you want to use to store the data from the worksheet from the **Assign value to the variable** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Get worksheet names action

The Get worksheet names action of the Excel advanced package enables you to get the names of all the worksheets and assign them to a list variable of string data type.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Select a string variable that you want to use to store the name of the worksheet from the **Assign the output to variable** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Hide worksheet action

The Hide worksheet action of the Excel advanced package enables you to hide a worksheet from the current workbook.

Settings

- Specify the name of the worksheet to hide in the **Enter worksheet name to hide** field.

Note: You can hide a worksheet only if the workbook contains more than one worksheet.

- Enter the name of the session used to open the workbook with the **Open** .

Password protect worksheet action

The **Password protect worksheet** action of the Excel advanced package enables you to protect a worksheet with a password. You can also specify the operations to restrict on the worksheet.

Settings

- Double-click or drag the **Password protect worksheet** action from the Excel advanced package in the **Actions** palette.
- Use the **Password** field to select one of the following options to specify the password you want to use to protect the worksheet:
 - **Credential:** To use a value available in the Credential Vault.
Click the **Pick** button to select a credential.
 - **Variable:** To use a value that is stored as a credential variable.

- **Insecure string:** To manually specify the values.
(Optional) Click the **Insert a value** icon to insert an existing variable.

- (Optional) Select any of the check boxes for the operation that you want to restrict on the worksheet.

For example, select the **Delete row** and **Delete column** check boxes to restrict a user from deleting a row or column from the worksheet.

Note: The functionality of the **Edit objects** and **Edit scenarios** are different from the other options. When you select these options in the Excel advanced package, they are disabled in the Microsoft Excel. For more information, see [Worksheet Protect method](#).

- Use the **Session name** field to select one of the following options:
 - **Session name:** Enter the name of the session used to open the workbook with the **Open** .
 - **Variable:** Enter the session variable that you have used in the **Set session variable** action or in the parent bot.

Rename worksheet action

The Rename worksheet action of the Excel advanced package enables you to rename a worksheet in the current workbook.

Settings

- Specify the index number or name of the worksheet to rename in the **Sheet by Index** or **Sheet by Name** field.

The index number is the number assigned to a worksheet. For example, if you want to perform an operation on the worksheet at the third position in the workbook, enter 3 in the field.

Note: You cannot rename the worksheet if a worksheet with the same name already exists in the workbook.

- Enter the new worksheet name that is under 31 characters.
- Enter the name of the session used to open the workbook with the **Open** .

Retrieve sheets count action

The Retrieve sheets count action of the Excel advanced package enables you to get the number of sheets available in the current workbook and store it in a number variable.

Settings

- Select the appropriate option to specify whether to include the hidden worksheet or not and assign the count to a variable.
- Enter the name of the session used to open the workbook with the **Open** .
- Select a number variable that you want to use to store the name of the worksheet from the **Select the variable to assign to** list. The shows a descriptive default variable name. If you

create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Run macro action

The Run macro action in the Excel advanced package enables you to run macros in a worksheet.

Settings

- Specify the name of the macro you want to run and its arguments.
- Enter the name of the session used to open the workbook with the **Open** .

Note:

- When you write a macro code, always end the code by adding `Exit Sub`.
- If you add `End` to terminate the macro, then on execution, the bot can fail with an error.
- Ensure that a macro code contains only one instance of the `End` or `End Sub` statement in the macro code to terminate the macro. If there is more than one instance of the statement, then on execution, the bot might fail with an error.

Example:

```
Public Sub main()  
MsgBox "Hello"  
MsgBox "Hello2"  
End Sub
```

Switch to sheet action

The **Switch to sheet** action enables you to activate the specified worksheet from the selected Microsoft Excel file.

Settings

- Double-click or drag the **Switch to sheet** action from the **Excel advanced** package in the **Actions** palette.
- Use the **Activate sheet by** field to select one of the following options:
 - **Index**: to specify the number of the worksheet from which you want to get the number of rows.
Ensure that the number is not 0 as the worksheet numbers start from 1.
 - **Name**:: to specify the name of the worksheet from which you want to get the number or rows.
- Use the **Session name** field to select one of the following tabs:
 - **Session name**: Enter the name of the session used to open the workbook with the **Open** .
 - **Variable**: Enter the Excel advanced session variable that you have created.
- Click **Save**.

Note: The bot containing the **Switch to sheet** action switches to the hidden worksheet and performs operations on it. After the operations are completed, the worksheet remains hidden and is not activated.

Unhide all worksheets action

The Unhides all worksheets action in the Excel advanced package unhides all the worksheets in the current workbook.

Settings

Unhides all worksheets in the current workbook. Enter the name of the session used to open the current workbook with the **Open** action.

Unhide worksheet action

The Unhide worksheet action in the Excel advanced package unhides a specific worksheet in the current workbook.

Settings

- Enter the name of the worksheet you want to unhide.
- Enter the name of the session used to open the workbook with the **Open** .

Write from data table action

The Write from data table action in the Excel advanced package enables you to write values from a data table into a worksheet.

Settings

- Specify the data table variable that contains the data you want to write in a worksheet.
- Specify whether you want to write data in the currently **Active worksheet** or **Specific worksheet**.
- Specify the address of the cell that you want to use as the starting point of the data in the **Specify the first cell** field.
- Enter the name of the session used to open the workbook with the **Open** .

Row and column operations in Excel advanced

The **Excel advanced** package contains various actions that you can use to automate tasks related to the row and column operations in a Microsoft Excel spreadsheet.

Row and column actions in the Excel advanced package

The **Excel advanced** package includes the following actions:

Action	Description
Get column name	See Get column name action on page 2496
Get row number	See Get row number action on page 2496
Hide rows/columns in selection	See Hide rows/columns in selection action on page 2497
Insert/Delete Rows/Columns	See Using Insert/Delete rows/columns action on page 2497.
Read column	See Read column action on page 2498
Read row	See Read row action on page 2498
Remove blank rows	See Remove blank rows action on page 2499
Select cell(s)/row(s)/column(s)	See Using Select action for cells, rows, and columns on page 2499.
Unhides rows/columns in selection	See Unhides rows/columns in selection action on page 2499

Get column name action

The Get column name in the Excel advanced package enables you to retrieve the column name that contains the specific cell and stores it to a string variable. This action supports .xlsx and .xlsm files.

Settings

- Select the **Active cell** or **Specific cell** option to specify the cell location.
- Enter the name of the session used to open the workbook with the **Open** .
- Select a string variable from the **Save the column name to variable** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Get row number action

The Get row number action in the Excel advanced package enables you to retrieve the row number that contains the specific cell and stores it to a string variable. This action supports .xlsx and .xlsm files.

Settings

This action supports .xlsx and .xlsm files.

- Select the **Active cell** or **Specific cell** option to specify the cell location.
- Enter the name of the session used to open the workbook with the **Open** .
- Select a string variable from the **Save the row number to variable** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Hide rows/columns in selection action

The Hide row/columns in selection action in the Excel advanced package enables you to hide rows or columns in the current worksheet.

Settings

- Select the appropriate option to specify whether to hide one or more rows and columns.
- Enter the name of the session used to open the workbook with the **Open** .

Using Insert/Delete rows/columns action

Use the **Insert/Delete rows/columns** action to add or remove rows or columns from the current worksheet or CSV file.

To change the name or value of an **Active cell** or a **Specified cell** in a Microsoft Excel spreadsheet or a CSV file in a row or a column, see [Set cell](#).

To insert or delete rows or columns in a worksheet, do the following:

1. Double-click or drag the **Insert/Delete rows/columns** action from the **Excel advanced** node in the **Actions** palette.
2. Select one of the following options:

- **Row operations:** if you want to insert or delete rows from the spreadsheet.

Select one of the following options under **Row operations**:

- **Insert Row at:** to insert a row and specify the location where you want to insert the row in the field.
- **Delete Row(s) at:** to delete rows.

You must specify the row number you want to delete in the field. For example, if you want to delete the tenth row in the worksheet, you must enter 10 in the field. Similarly, if you want to delete the first five rows, you must enter 1 : 5 in the field.

- **Column operations:** if you want to insert or delete columns from the spreadsheet.

Select one of the following options under **Column operations**:

- **Insert Column at:** to insert a column and specify the location where you want to insert the column in the field.
- **Delete Column(s) at:** to delete columns.

You must specify the address of the column you want to delete in the field. For example, if you want to delete column 'D' in the worksheet, you must enter D in the field. Similarly, if you want to delete the first five columns, you must enter A : E in the field.

Note: You cannot insert multiple rows or columns in an Excel worksheet. Instead, you can loop this action any number of times in order to add multiple rows or column.

3. Use the **Session name** field to select one of the following tabs:
 - **Session name:** Enter the name of the session used to open the workbook with the **Open** .

- **Variable:** Enter the Excel advanced session variable from **Set session variable** action or from the parent bot.

4. Click **Save**.

Read column action

The Read column action in the Excel advanced package enables you to extract data from a column and stores it in a list variable of string data type.

Settings

- Select the **From active cell** or **From specific cell** option to specify the starting point. You can also select the **Read full column** option to extract data for the entire column.
- Choose from the **Read** option to read either the visible text or value of the cell.

For example, if the cell has 70% as cell content, **Read cell value** option will read the value as 70 ignoring the % format whereas **Read visible text** option will read the content as 70%.

Recommendation: Use the **Read cell value** option as reading value from a cell for better performance than reading visible text.

- Enter the name of the session used to open the workbook with the **Open** .
- Select a table variable to store the extracted values.

Note: This action overwrites any existing values in the selected table.

The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Read row action

The Read row action in the Excel advanced package enables you to extract data from a row and stores it in a list variable of string data type.

Settings

Extracts data from a row and stores it in a list variable of string data type.

- Select the **From active cell** or **From specific cell** option to specify the starting point. You can also select the **Read full row** option to extract data for the entire row.
- Choose from the **Read** option to read either the visible text or value of the cell.

For example, if the cell has 70% as cell content, **Read cell value** option will read the value as 70 ignoring the % format whereas **Read visible text** option will read the content as 70%.

Recommendation: Use option **Read cell value** as reading value from a cell gives better performance than reading a visible text.

- Enter the name of the session used to open the workbook with the **Open** .

- Select a list variable of string data type that you want to use to store the extracted values. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Remove blank rows action

The Remove blank rows action in the Excel advanced package enables you to remove blank rows from the current worksheet.

Settings

You can specify the range from which you want to delete the blank rows.

Using Select action for cells, rows, and columns

Use the **Select** action to select cells, rows, or columns.

To select cells, rows, or columns do the following:

1. Double-click or drag the **Select** cell, row, or column action from the **Excel** node in the **Actions** palette.
2. Select an option from the **Select** list to specify whether you want to select a cell, row, or column.
 - a) If you have selected the **Cell** option, select any of the following options:
 - **Active cell**: Enables you to select the active cell from the worksheet.
 - **Specific cell**: Enables you to select the cell you have specified in the field.
 - **Cell range**: Enables you to select all the cells in the range you have specified in the field.
 - **All cells in the sheet**: Enables you to select all the cells in the worksheet.
 - b) If you have selected the **Column** option, select any of the following options:
 - **Column of active cell**: Selects the column of the current active cell in the worksheet.
 - **Specific column**: Enables you to select the column you have specified in the field.
 - **Column range**: Enables you to select all the columns in the range you have specified in the field.
 - c) If you have selected the **Row** option, select any of the following options:
 - **Row of active cell**: Selects the row of the current active cell in the worksheet.
 - **Specific row**: Enables you to select the row you have specified in the field.
 - **Row range**: Enables you to select all the rows in the range you have specified in the field.
3. Enter the name of the session used to open the workbook with the **Open** .
4. Click **Save**.

Unhides rows/columns in selection action

The Unhide rows/columns in selection action in Excel advanced package enables you to unhide the hidden rows or columns in the current worksheet.

Settings

- Select the appropriate option to specify whether you want to unhide a row or column and which row or column to unhide.
- Enter the name of the session used to open the workbook with the **Open** .

Cell operations in Excel advanced

The **Excel advanced** package contains various actions that you can use to automate tasks related to cell operations.

Cell actions in the Excel advanced package

The **Excel advanced** package includes the following actions:

Action	Description
Delete cells	See Delete cells action on page 2501
Find next empty cell	See Using Find next empty cell action on page 2501.
Find	See Using Find action in Excel on page 2501.
Get cell address	See Using the Get cell address action on page 2502
Get cell color	See Using Get cell color action on page 2504.
Get multiple cells	See Get multiple cells action on page 2504
Get number of rows	See Using Get number of rows action on page 2505.
Get single cell	See Get single cell action on page 2506
Go to cell	See Go to cell action on page 2506
Go to next empty cell	See Go to next empty cell action on page 2507
Read cell formula	See Read cell formula action on page 2507
Replace	See Using the Replace action on page 2507.
Set cell	See Set cell action on page 2508
Set cell formula	See Set cell formula action on page 2509

Delete cells action

The Delete cell action in the Excel advanced package enables you to delete the Active cell or a Specific cell from the current worksheet or a CSV file.

Settings

Note: You can enter a cell range in the **Specific - cell** field using the `starting - cell:ending cell` format. For example, to perform this operation on all cells in the second row and from the first through third column, enter `A2:C2`.

After deleting the cell, you can:

- **Shift cells left:** Deletes the specified cell and shifts the cell one position to the left.
- **Shift cells up:** Deletes the specified cell and shifts the cell one position up.
- **Entire row:** Deletes the entire row that contains the cell you have specified to delete.
- **Entire column:** Deletes the entire column that contains the cell you have specified to delete.

Using Find next empty cell action

Use the **Find next empty cell** action to find the next empty cell in the current worksheet.

To find the next empty cell, do the following:

1. Double-click or drag the **Find next empty cell** action from the **Excel** node in the **Actions** palette.
2. Select the **row** or **column** option from the **Traverse by** section to specify whether you want to find the empty cell in a row or column.
3. Select the **active cell** or **specific cell** option from the **Start from** section to specify the point from where you want to start the search.
4. Select the string variable you want to use to store the address of the empty cell from the **Assign the output to variable** list.
The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.
5. Enter the name of the session used to open the workbook with the **Open**.
6. Click **Save**.

Using Find action in Excel

Use the **Find** action to find a particular string in a Microsoft Excel spreadsheet or a CSV file.

To find a value in a Microsoft Excel spreadsheet, do the following:

1. Double-click or drag the **Find** action from the **Excel** node in the **Actions** palette.
2. Select an option from the **From** list to specify a starting point of the cell range for search:
 - **Beginning:** Starts the search from the beginning of the spreadsheet.
 - **End:** Starts the search from the end of the spreadsheet.
 - **Active cell:** Starts the search from the active cell in the spreadsheet.
 - **Specific cell:** Enables you to specify the address of the cell from where you want to start the search.

3. Select an option from the **Till** list to specify an end point of the cell range for search:
 - **Beginning**: Ends the search at the beginning of the spreadsheet.
 - **End**: Ends the search at the end of the spreadsheet.
 - **Active cell**: Ends the search at the active cell in the spreadsheet.
 - **Specific cell**: Enables you to specify the address of the cell where you want to end the search.
4. Specify the string you want to search for in the **Find** field.
5. Select from the following search options:
 - **By rows**: Enables you to search by rows.
 - **By columns**: Enables you to search by columns.
 - **Match case**: Only performs this action on cells that contain a string that matches the uppercase and lowercase characters of the string you specified in the **Find** field.
 - **Match entire cell contents**: Enables you to find only those cells that contain the entire string you have specified in the **Find** field.
6. Enter the name of the session used to open the workbook with the **Open** .
7. Select the list variable of string data type that you want to use to store the output from the **Assign cell addresses to variable** list.
8. Click **Save**.

When you search for a value using the **Find** action, it will either return a list of cell addresses that contain the value or will return an empty list if the value is not found.

Using the Get cell address action

Use the Get cell address action to retrieve the location of the active cell and store it to a string variable. This action supports .xlsx and .xlsm files.

Open a worksheet using the **Open** action. You must select the **Contains header** option when configuring the **Open** action in order to use this action to retrieve the cell address based on the column title name.

1. Double-click or drag the **Get cell address** action from the Excel advanced node in the **Actions** palette.
2. Select whether to retrieve the cell address from the **Active cell** or **Based on header**:

Option	Steps
Active cell	If you select this option, the bot will retrieve the cell address of the currently active cell. Skip to Step 5.

Option	Steps
Based on header	<p>If you select this option, the bot will retrieve the cell address of the cell specified by the column title name and cell position. Complete the following fields:</p> <p>a) Enter the column title: If you selected the Sheet contains header option when you opened this sheet using the Open action, enter the column name. For example, <code>First Name</code>.</p> <p>If you did not select that option, enter the default column name. For example, <code>A</code>.</p> <hr/> <p>Note: This field is not case-sensitive.</p> <hr/> <p>b) Enter cell position from column title: Enter the number of cells between the header cell and the cell from which you want to retrieve the address. Enter up to three digits.</p> <p>For example, if the header cell is located at B1 and you specify 2 as the cell position, the action will return B3.</p>

3. Select whether to retrieve the cell address from the **Active cell** or a **Specific cell**.
 - If you have selected the **Active cell** option, the bot will retrieve the cell address of the currently active cell. Skip to Step 5.
 - If you have selected the **Specific cell** option, the bot will retrieve the cell address of the cell specified by the column title name and cell position. Complete the following fields:
 - **Enter the column title:** Enter the column name. For example, `Name`.

Note: This field is not case-sensitive.

 - **Enter cell position from column title:** Enter the number of cells between the header cell and the cell from which you want to retrieve the address. Enter up to three digits.

For example, if the header cell is located at B1 and you specify 2 as the cell position, the action will return B3.
4. In the **Save active or user specified cell address in local variable** field, create or insert an existing string variable.
The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.
5. Enter the name of the session used to open the workbook with the **Open**.
6. Click **Save**.

Next, you can insert the string variable containing the cell address into the **Specific cell** field of actions related to cell operations. See [Cell operations in Excel advanced](#) on page 2500.

Using Get cell color action

Use the **Get cell color** action to get the color of the background or text in a cell.

This action retrieves the color of a cell as RGB values. For example, if the background or text in a cell is of red color, the value retrieved is 255,0,0.

1. Double-click or drag the **Get cell color** action from the **Excel** node in the **Actions** palette.
2. Select the **Background color** option to get the background color of the cell or the **Text color** option to get the color of the text.
3. Select the **Active cell** option to get the color from the current active cell or the **Specific cell** option to get the color from the address of the cell you have specified.
4. Select a variable from the **Assign the output to variable** list to assign the address of the empty cell to the variable you have selected from the list.
5. Select the string variable you want to use to store the address of the empty cell from the **Assign the output to variable** list.
The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.
6. Enter the name of the session used to open the workbook with the **Open** .
7. Click **Save**.

Get multiple cells action

The **Get multiple cells** action in the Excel advanced package enables you to retrieve the values from the cells in a Microsoft Excel spreadsheet and store them in a table variable.

Settings

This retrieves cell values as string data types. It supports Excel cell formats, including Number, Percentage, Currency, Scientific, and Date. For example, a value from a cell of Currency formatting retains the currency symbol when passed to a table or record variable.

Note: You must convert the values to perform non-string operations.

- Use the **Select range of cells to be returned** drop-down to select one of the following options:

- **All rows:** Select one of the following options under **Read options**:
 - **Read visible text in cell:** cell value is read as is.
 - **Read cell value:** formatting is ignored while reading the cell value.

For example, if the cell content is '70%', **Read visible text in cell** option will read the content as 70%, whereas the **Read cell value** option will read the value as 70 ignoring the '%' format.

Recommendation: Use the **Read cell value** option as the reading value for a better performance than reading visible text.

- **Specific rows:** Use the following fields to specify the rows:
 - **From row**

- **to row**
- **Cell range:** Use the following fields to specify the range for cells:
 - **From cell**
 - **To cell**
- Enter the name of the session used to open the workbook with the **Open** .
- Select a table variable to store the retrieved values in the **Assign value to variable** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Using Get number of rows action

Use the **Get number of rows** action to get the number of rows that contain data.

1. Double-click or drag the **Get number of rows** action from the **Excel advanced** package in the **Actions** palette.
2. Use the **Select worksheet by** field to select one of the following options:
 - **Index:** to specify the number of the worksheet from which you want to get the number of rows.
Ensure that the number is not 0 as the worksheet numbers start from 1.
 - **Name:** to specify the name of the worksheet from which you want to get the number or rows.
3. Select one of the following options:
 - **Non-empty rows:** returns the total number of non-empty rows only.
 - **Total rows with data:** returns the total number of rows including empty cells.

Consider the following illustration of an Excel file for monthly sales target achieved:

	A	B
1	Month	Target achieved
2	May	75%
3	June	60%
4		
5	September	82%
6		
7	November	90%

- **Non-empty rows:** returns the value 5.
The rows 1, 2, 3, 5 and 7 are not empty.
 - **Total rows with data:** returns the value 7.
This includes empty and rows with data in the table.
4. Use the **Session name** field to select one of the following tabs:
 - **Session name:** Enter the name of the session used to open the workbook with the **Open** .
 - **Variable:** Enter the Excel advanced session variable that you have created.

5. Click the **Assign to variable** drop-down menu to select a variable that you want to assign the output value to.
Click the **Create variable** icon if you have not created a variable.
6. Click **Save**.

Get single cell action

The Get single cell action in the Excel advanced package enables you to retrieve the values from a single cell in a Microsoft Excel spreadsheet or a CSV file and store them in a string variable.

Settings

This retrieves cell values as string data types. It supports Excel cell formats, including Number, Percentage, Currency, Scientific, and Date. For example, a value from a cell of Currency formatting retains the currency symbol when passed to a table or record variable.

Note: You must convert the values to perform non-string operations.

- Select the **Active cell** option to retrieve the value from the active cell, or select **Specific cell** to retrieve the value from a specific cell in a Microsoft Excel spreadsheet.
- Choose from the **Read** option to read either the visible text or value of the cell.
For example, if the cell has 70% as cell content, **Read cell value** option will read the value as 70 ignoring the % format whereas **Read visible text** option will read the content as 70%.

Recommendation: Use the **Read cell value** option as the reading value from a cell for a better performance than reading visible text.

- Enter the name of the session used to open the workbook with the **Open** .
- Select a string variable to store the retrieved values in the **Store cell contents to** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Note: If the character limit in a single cell of a Microsoft Excel spreadsheet exceeds 8200, then the bot reads only the first 8200 characters. This behaviour is specific only to Microsoft Excel spreadsheet.

[Example of using a conditional statement](#) on page 3078

Go to cell action

The Go to cell action in the Excel advanced package enables you to move the cursor to a specific cell in a Microsoft Excel spreadsheet or a CSV file.

Settings

- Select the **Specific cell** option to specify the cell to which the cursor should be moved, or select an option from the **Active cell** list.

Note: You can enter a cell range in the **Specific cell** field to select the entire range of cells. For example, to select all the cells in the second row and from the first through third column, enter `A2 : C2`.

- Enter the name of the session used to open the workbook with the **Open** .

Go to next empty cell action

The Go to next empty cell action in the Excel advanced package enables you to find the next empty cell in the current worksheet. You can specify whether to find the empty cell toward the left, right, up, or down.

Settings

- Select the **Active cell** or **Specified cell** option to specify the cell from which to start searching for the empty cell. If you have selected the **Specified cell** option, specify the address of the cell in the field.
- Select the **left**, **right**, **up**, or **down** option to specify the direction in which to search for the next empty cell.
- Enter the name of the session used to open the workbook with the **Open** .

Read cell formula action

The Read cell formula action in the Excel advanced package enables you to retrieve the formula available in the **Active cell** or **Specified cell** and assign the output to a string variable. This action returns a blank value if the specified cell does not contain a formula.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Select the **Active cell** or **Specified cell** option to specify the cell from which to read the formula. If you have selected the **Specified cell** option, specify the address of the cell in the field.
- Select a string variable to store the name of the formula from the **Assign the output to variable** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Using the Replace action

Use the **Replace** action to find cells that contain a specific string and replace it with another string. This action supports .xlsx, .xlsm, and .csv files.

1. Double-click or drag the **Replace** action from the Excel advanced node in the **Actions** palette.
2. Select an option from the **From** list to specify a starting point of the cell range for search:
 - **Beginning:** Starts the search from the beginning of the spreadsheet.
 - **End:** Starts the search from the end of the spreadsheet.
 - **Active cell:** Starts the search from the active cell in the spreadsheet.

- **Specific cell:** Enables you to specify the address of the cell from where you want to start the search.
3. Select an option from the **Till** list to specify an end point of the cell range for search:
 - **Beginning:** Ends the search at the beginning of the spreadsheet.
 - **End:** Ends the search at the end of the spreadsheet.
 - **Active cell:** Ends the search at the active cell in the spreadsheet.
 - **Specific cell:** Enables you to specify the address of the cell where you want to end the search.
 4. Specify the string you want to search for in the **Find** field.
 5. Select from the following search options:
 - **By rows:** Enables you to search by rows.
 - **By columns:** Enables you to search by columns.
 - **Match case:** Only performs this action on cells that contain a string that matches the uppercase and lowercase characters of the string you specified in the **Find** field.
 - **Match entire cell contents:** Enables you to find only those cells that contain the entire string you have specified in the **Find** field.
 6. Select **Replace with** and specify the replacement string, or leave the field blank to replace the matching cells with an empty character.
 7. Enter the name of the session used to open the workbook with the **Open** .
 8. Click **Save**.

Set cell action

The **Set cell** action enables you to set a value into an Active or Specific cell within a Microsoft Excel spreadsheet or a CSV file.

Settings

- Double-click or drag the **Set cell** action from the **Excel advanced** package in the **Actions** palette.
- Use the **Cell option** field to select one of the following:
 - **Active cell:** to select a cell from the Excel sheet that you have specified in the **Session name** field.
 - **Specified cell:** to specify the address of the cell from the Excel sheet.

Note: You can enter a cell range in the **Specified cell** field to set a particular value. For example, to set a value of 5 in all cells in the second row and from the first through third column, enter **A2 : C2**.

- In the **Cell value** field, enter the value that you want to set.
- Enter the name of the session used to open the workbook with the **Open** .
- Click **Save**.

Set cell formula action

The Set cell formula action in the Excel advanced package enables you to set a formula in the active cell or a specific cell in a Microsoft Excel spreadsheet or a CSV file.

To generate a random number, use the **Number > Random** action. See [Random action](#).

Settings

- Select the **Set formula for active cell** or **Set formula for specified cell** option to specify the cell in which to set the formula. If you have selected the **Set formula for specified cell** option, specify the address of the cell in the field.
- Enter the formula to set in the **Enter formula for specific cell** field.
- Enter the name of the session used to open the workbook with the **Open** .

Table operations in Excel advanced

The **Excel advanced** package contains various actions that you can use to automate tasks related to table operations in a Microsoft Excel spreadsheet.

Table actions in the Excel advanced package

Note: Ensure that a table is available in the workbook. A worksheet that contains data in various rows and columns is not considered as a table.

The **Excel advanced** package includes the following actions:

Action	Description
Delete table column	See Delete table column action on page 2509
Filter table	See Using Filter table action on page 2510.
Get table range	See Get table range action on page 2511
Insert table column	See Insert table column action on page 2511
Sort table	See Sort table action on page 2511

Delete table column action

The Delete table column action in the Excel advanced package enables you to delete a column in a table.

Settings

- Specify the **Table name** from which you want to delete a column.

Note: The table name is a string value. It is NOT a data table name. For information on how to retrieve the Excel table name, see [Rename an Excel table](#).

- Select the **Name** or **Position** to specify the name or position of the column to delete.
- Enter the name of the session used to open the workbook with the **Open** .

Using Filter table action

Use the **Filter table** action to filter data from a column in a table.

1. Double-click or drag the **Filter table** action from the **Excel** node in the **Actions** palette.
2. Specify the name of the table where you want to filter data in the **Table name** field.

Note: The table name is a string value and NOT a data table name. For information on how to retrieve the Excel table name, see .

3. Use one of the following options to specify the column of the table where you want to filter the data:
 - **Column name:** To specify the name of the column.
 - **Column position:** To specify the position of the column.

For example, you have a table called `Monthly sales` that contains three columns: `April`, `May` and `June`. If you want to filter the data of the column `May` in the table, enter **May** in the **Column name** field or enter **2** in the **Column position** field.

4. Use one of the following options to select the type of filter:
 - **Number:** If the column you have specified contains number data.
Click the drop-down menu to select one of the following filters:
 - **Equals:** Filters the data that is equal to the value you have specified.
 - **Does not equal:** Filters the data that is not equal to the value you have specified.
 - **Greater than:** Filters the data that is greater than the value you have specified.
 - **Greater than or equal to:** Filters the data that is greater than or equal to the value you have specified.
 - **Less than:** Filters the data that is less than the value you have specified.
 - **Less than or equal to:** Filters the data that is less than or equal to the value you have specified.
 - **Between:** Filters the data that is between the two values you have specified.

- **Text:** If the column you have specified contains textual data.
Click the drop-down menu to select one of the following filters:
 - **Equals:** Filters the data that is equal to the value you have specified.
 - **Does not equal:** Filters the data that is not equal to the value you have specified.
 - **Begins with:** Filters the data that begins with the value you have specified.
 - **Ends with:** Filters the data that ends with the value you have specified.
 - **Contains:** Filters the data that contains the value you have specified.
 - **Does not contain:** Filters the data that does not contain the value you have specified.

From the `Monthly sales` table example mentioned above, consider a scenario where you want to only view data that is greater than the target number of 150 in the `May` column. So in step 3, you select **Column name** and enter `May`. You can then use the **Number > Greater than** option and enter 150 in the field to filter the column values.

5. Enter the name of the session used to open the workbook with the **Open** .

You can also click the **Variable** tab and select an existing Excel advanced session variable.

6. Click **Save**.

Get table range action

The Get table range action in the Excel advanced package enables you to get the range of a table available in a worksheet and store the output in a string variable.

Settings

- Specify the **Table name** for which you want to get the range.

Note: The table name is a string value and NOT a data table name. For information on how to retrieve the Excel table name, see .

- Select the options to specify whether you want to include a header and pivot table in the range and a variable to store the output. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.
- Enter the name of the session used to open the workbook with the **Open** .

Insert table column action

The Insert table column action in the Excel advanced package enables you to insert a column in a table.

Settings

- Specify the **Table name** in which you want to insert a column.

Note: The table name is a string value and NOT a data table name. For information on how to retrieve the Excel table name, see .

- Specify the name of the column in the **Column name** field and the position where you want to insert the column in the **Column position** field.
- Enter the name of the session used to open the workbook with the **Open** .

Sort table action

The **Sort table** action in the Excel advanced package enables you to sort numeric and text data within a specific column of a table.

Settings

Important: Ensure that Microsoft Excel is set to the same language as that of the computer operating system.

- Specify the **Table name** for which you want to sort the data.

Note: The table name is a string value and NOT a data table name. For information on how to retrieve the Excel table name, see .

- In **Sort for**, select one of the following options:
 - Column name:** Enter the column name or click the **Insert a value** icon to select an existing variable.
 - Column position:** Enter the column number or click the **Insert a value** icon to select an existing variable.

For example, you have a table called `Monthly sales` that contains three columns: `April`, `May` and `June`. If you want to sort the order of the column `May` in the table, enter `May` in the **Column name** field or enter `2` in the **Column position** field.
- In **Sort order**, select one of the following options:
 - Number:** Click the drop-down menu to select an ascending or descending sort order for the values in the column.
 - Text:** Click the drop-down menu to sort the column values in an alphabetical order (A-Z or Z-A).

From the previous example, if the `May` column contains numerical values and you want to sort them in a descending order, select **Number** > **Largest to smallest** in the drop-down menu. However, if the values are alphabets or text, select **Text** > **Z-to-A**.
- Enter the name of the session used to open the workbook with the **Open** .
You can also click the **Variable** tab and select an existing Excel advanced session variable.

CSV operations in Excel advanced

You can use some of the actions available in the **Excel advanced** package to perform various operations on a CSV file.

CSV actions in the Excel advanced package

The following table lists the actions that you can use with a CSV file:

Supported	Not Supported
Open	Find next empty cell
Set cell	Get cell colour
Go to cell	Go to next empty cell
Insert/Delete row column	Run macro
Insert/Delete row column	Unhide all worksheets
Get cell	Hide row/column in selection
Find/Replace	Unhide row/column in selection
Convert excel to pdf	Access password protected worksheet
Delete cells	Protect/Unprotect workbook

Set cell formula	Table related commands
Create workbook	Create worksheet

You can use the **Loop** action to retrieve data from each row in a CSV file. You can also use any of the above action that supports the use of a CSV file within a **Loop** action.

Note: All the other actions available in the **Excel advanced** package that are not listed in the above table cannot be used with a CSV file.

File package

Automate various file-related operations, such as creating, opening, copying, renaming, and deleting a file, by using the actions available in the File package.

You can use the actions in the File package either individually, to perform an action one time, or in a **Loop** action, to perform that action for each file available in a folder.

Actions in the File package

Note: You can use the **Zip** action available in the Folder package to compress a file. See [Zip action](#) on page 2524.

The File package includes the following actions:

Action	Description
Assign	See Assign action on page 2514
Copy Desktop file	See Using Copy Desktop file action for file on page 2514.
Create	See Create action on page 2516
Copy Control Room file	See Copy Control Room file action on page 2517
Create shortcut	. See Create shortcut action on page 2523
Create symbolic link	See Create symbolic link action on page 2523
Delete	See Using Delete action for file on page 2516.
Get name	See Get name action on page 2518
Get path	See Get path action on page 2518
Open	See Open action on page 2519
Print	See Using Print action for file on page 2519.

Action	Description
Print multiple files	See Using Print multiple files action on page 2520.
Rename	See Using Rename action for file on page 2522.

Review the updates in released versions of the File package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Assign action

The Assign action in the File package enables you to assign a file from the Control Room , Desktop, or an existing File variable to a user-defined File variable.

Settings

Assigns a file from the Control Room , Desktop, or an existing File variable to a user-defined File variable.

Using Copy Desktop file action for file

Use the **Copy Desktop file** action to copy an existing file from Desktop to another location. This action enables you to copy a file based on its size and the date it was created or modified.

To copy an existing file, follow these steps:

1. In the Actions palette, from the File package, double-click or drag the **Copy Desktop file** action.
2. From the **Source file** field select one of the following options:
 - **Specific:** Specify the name and location of the file.
 - For **Regex:** Specify the source folder path.

You can use a regular expression (regex) in your source file or folder path to support a pattern-based search. Select the regular expression either as a **String** or **Pattern** for each regular expression condition and enter the value.

For example, if want to copy, delete, rename or print multiple files from your source folder using pattern based search, use regular expressions either as a **String** and enter the value

as `My_` for all file_name starting with `My_` or as a **Pattern** such as `[a-z]{3}(.txt|xlsx)` to retrieve files that matches this pattern.

3. In the **Destination file/folder** field, specify the name of the file and location.
4. Select the **Overwrite existing files** check box to overwrite an existing file with the same name at the specified location.
 - If the **Overwrite existing files** option is not selected, the system appends the name of the copied file with a numeric value. For example, if you have copied a file named `June_Quarter_report.pdf` and a file with the same name exists in the location where you want to save the copied file, the system saves the copied file as `Copy of June_Quarter_report.pdf` for the first time. When you copy the same file in the same folder for the second time, it saves the copied file as `Copy (2) of June_Quarter_report.pdf`. The numeric value is incremented each time you copy a file with the same name when the overwrite check box is not selected.
 - If you want to copy a file that is already available in the destination folder where the source and the destination folders are different and the **Overwrite existing files** check box is not selected, then the system shows the following error message: `Unable to copy file(s) <path\filename> as the specified file(s) exists.`
5. Select the **Copy multiple files at the same time to increase the copy speed** check box to copy large number of files simultaneously thus improving the speed of copy operation.

Note: If you already have existing automations to copy large files that is taking more time and have dependent automations that are tuned per the existing copy speed, then when you use the **Copy multiple files at the same time to increase the copy speed** option, ensure that you make specific adjustments to your bot code per the increased copy speed before you use the option.

6. Select the **Size** check box to copy a file based on its size.
 - a) Select any of the following options from the list:
 - **Atleast:** Copies a file only if the file size is more than the size you have specified.
 - **Atmost:** Copies a file only if the file size is less than the size you have specified.
 - **Exact:** Copies a file only if the file size is the same as the size you have specified.
 - b) Specify a value in the **Size** field.
7. Select the **Date** check box to copy a file based on the date it was created or modified.
 - a) Select one of the options from the list:
 - **Created:** Enables you to copy a file based on the date it was created.
 - **Modified:** Enables you to copy a file based on the date it was modified.
 - b) Select the **Is within last** option and specify a value in the field.

This option enables you to perform the operation on the file if it was created or modified within the number of days you have specified. For example, if you specify 7 in the field, the system performs the operation on the file if it was created or modified in the last 7 days.
 - c) Select the **Is between** option to specify a period.

This option enables you to specify a **Start date** and an **End date** for the period. For example, if you specify 01/01/19 as the start date and 01/31/19 as the end date of

the period, the system performs the operation on the file if it was created or modified between this period.

Note: The **Start date** and **End date** are included in the period.

- d) Select the **Is before** option and specify a value in the field.
This option enables you to perform the operation on the file if it was created or modified on or before the date you have specified.
- e) Select the **On a date** option and specify a date in the field.
This option enables you to perform the operation on a file if it was created or modified on the date that you specified.

8. Click **Save**.

Create action

The Create action in the File package enables you to create a new file.

Settings

- In the **File** field, specify the name including the location to store the file.
- In the **Overwrite an existing file** option, select an existing file with the same name to overwrite it. If existing files are not overwritten, the Control Room appends the name of the new file with a numeric value.

Using Delete action for file

Use the **Delete** action to delete a file. This action enables you to delete a file based on its size and the date it was created or modified.

Follow these steps to delete a file:

1. In the **Actions** palette, double-click or drag the **Delete** action from the **File** package.
2. From the **Source file** field select one of the following options:
 - **Specific:** Specify the name and location of the file.
 - For **Regex:** Specify the source folder path.

You can use a regular expression (regex) in your source file or folder path to support a pattern-based search. Select the regular expression either as a **String** or **Pattern** for each regular expression condition and enter the value.

For example, if want to copy, delete, rename or print multiple files from your source folder using pattern based search, use regular expressions either as a **String** and enter the value as `MY_` for all file name starting with `MY_` or as a **Pattern** such as `[a-z]{3}(.txt|xlsx)` to retrieve files that matches this pattern.

Note: If the file does not exist in the file path, an error message is displayed.

3. Select the **Size** check box to delete a file based on its size.
 - a) Select any of the following options from the list:

- **Atleast:** Deletes a file only if the file size is more than the size you have specified.
 - **Atmost:** Deletes a file only if the file size is less than the size you have specified.
 - **Exact:** Deletes a file only if the file size is the same as the size you have specified.
- b) Specify a value in the **Size** field.
4. Select the **Date** check box to delete a file based on the date it was created or modified.
- a) Select one of the options from the list:
- **Created:** Enables you to delete a file based on the date it was created.
 - **Modified:** Enables you to delete a file based on the date it was modified.
- b) Use the second drop-down menu to select one of the following additional options:
- **Relative to runtime:** select this option and specify a value in the field. This option enables you to perform the operation on the file if it was created or modified within the number of days you have specified. For example, if you specify 7 in the field, the system performs the operation on the file if it was created or modified in the last 7 days.
 - **Between two dates:** To specify the time period.

This option enables you to specify a **Start date** and an **End date** of the period. For example, if you specify 01/01/19 and 01/31/19 as the start date and end date, the system performs the operation on the file if it was created or modified between these dates.
-
- Note:** The **Start date** and **End date** are included in the period.
-
- **On a date:** To specify a particular date.

This option enables you to set a specific date that a file was created or modified.
 - **Before a date:** To specify a date prior to which the files were created.

For example, if you set the date as 07/28/20, files created or modified before this date are selected
- Optional:** Select the **Including date** check box if you want include the date you have specified for the **Before a date** option.
5. Click **Save**.

Copy Control Room file action

The Copy Control Room file action in the File package enables you to copy a Control Room file to a specific location.

Settings

- In the **Control Room file** field, specify the file to copy. Select one of the following options to copy a file from the Control Room repository:

- **Static file path:** Enables you to browse the Control Room repository and select the file. Use this option when the file path is static.

Note: When you browse the Control Room repository using **Static file path**, files with the `.bot` extension are not displayed.

- **Dynamic file path:** Enables you to browse the Control Room repository and select the file. In addition, it also enables you to insert variables in a file path to copy a file from the Control Room repository where the file path is dynamic. You can insert a variable that holds the entire file path or part of the file path.

For example, `C:\user\My Docs\test.csv` or `C:\user\My Docs\${fileName}`

- In the **Target file path** field, specify the path to the location where you want to save the file. You can insert a variable that holds the entire file path or part of the file path.

For example, `C:\user\My Docs\test.csv` or `C:\user\My Docs\${fileName}`

Note: If the folder structure does not exist, the bot creates all the folders as needed.

- Select True or False, or insert a Boolean variable to specify whether to overwrite the existing file.

Get name action

The Get name action in the File package enables you to get the name and the extension of the file.

Settings

Do the following steps to retrieve the file name and extension:

1. In the **Source file** tab, select one of the following options to specify the location of your file:
 - **Control Room file:** Enables you to select the file that is available in a folder in the Control Room.
 - **Desktop file:** Enables you to select the file that is available on your device.
 - **Variable:** Enables you to specify the file variable that contains the location of the file.
2. In the **Save the outcome to a variable** field, select a string variable to save the output.

Get path action

The Get path action in the File package enables you to retrieve the file path.

Settings

Do the following steps to retrieve the file path:

1. In the **Source file** tab, select one of the following options to specify the location of your file:

- **Control Room file:** Enables you to select the file that is available in a folder in the Control Room.
- **Desktop file:** Enables you to select the file that is available on your device.
- **Variable:** Enables you to specify the file variable that contains the location of the file.

Note: When you select the **Control Room file** option to retrieve the file path, the bot displays the local file path of the downloaded Control Room file.

2. In the **Save the outcome to a variable** field, select a string variable to save the output.

Open action

The Open action in the File package enables you to open an existing file.

Settings

In the **File** field, specify the name including the location to store the file.

You can use a regular expression (regex) or a pattern-based search to open an existing file that matches the search criteria. Select the regular expression either as a **String** or **Pattern** for each regular expression condition and enter the value.

Using Print action for file

Use the **Print** action to print a file. This action enables you to print a file based on its size and the date it was created or modified.

Follow these steps to print a file:

1. In the Actions palette, double-click or drag the **Print** action from the File package.
2. In the **File** field, specify the name and location of the file.
3. Select the **Size** check box to print a file based on its size.
 - a) Select one of the options from the list:

- **Atleast:** Prints a file only if the file size is more than the size you have specified.
 - **Atmost:** Prints a file only if the file size is less than the size you have specified.
 - **Exact:** Prints a file only if the file size is the same as the size you have specified.
- b) Specify a value in the **Size** field.
4. Select the **Date** check box to print a file based on the date it was created or modified.
- a) Select any of the following options from the list:
- **Created:** Enables you to print a file based on the date it was created.
 - **Modified:** Enables you to print a file based on the date it was modified.
- b) Select the **Is within last** option and specify a value in the field.
This option enables you to perform the operation on the file if it was created or modified within the number of days you have specified. For example, if you specify 7 in the field, the system performs the operation on the file if it was created or modified in the last 7 days.
- c) Select the **Is between** option to specify a period.
This option enables you to specify a **Start date** and an **End date** for the period. For example, if you specify 01/01/19 as the start date and 01/31/19 as the end date of the period, the system performs the operation on the file if it was created or modified between this period.
-
- Note:** The **Start date** and **End date** are included in the period.
-
- d) Select the **Is before** option and specify a value in the field.
This option enables you to perform the operation on the file if it was created or modified on or before the date you have specified.
- e) Select the **On a date** option and specify a date in the field.
This option enables you to perform the operation on a file if it was created or modified on the date that you specified.
5. Click **Save**.

Using Print multiple files action

Use **Print multiple files** to print multiple files based on the size and the date they were created or modified.

Follow these steps to print multiple files:

1. In the **Actions** palette, double-click or drag the **Print multiple files** action from the **File** package.
2. In the **Folder** field, specify the name and location of the folder.
3. From the **File type** field, select **String** to specify the file type of your files or **Regex**
Use the regular expression in your source file or folder path to support pattern based search. Select the regular expression (Regex) either as a **String** or **Pattern** for each regex condition and input the regex value.

For example, you can use regular expressions either as a **String** and enter the value as `My_` for all file name starting with `My_` or as a **Pattern** such as `[a-z]{3}(.txt|xlsx)` to retrieve files that matches this pattern.

4. Select the **Include subfolders** check box to include all the subfolders in your selected folder.
5. Select the **Size** check box to print multiple files based on their size.
 - a) Select any of the following options from the list:
 - **Atleast**: Prints multiple files only if the file size is more than the size you have specified.
 - **Atmost**: Prints multiple files only if the file size is less than the size you have specified.
 - **Exact**: Prints multiple files only if the file size is the same as the size you have specified.
 - b) Specify a value in the **Size** field.
6. Select the **Date** check box to print multiple files based on the date they were created or modified.
 - a) Select one of the options from the list:
 - **Created**: Enables you to print multiple files based on the date they were created.
 - **Modified**: Enables you to print multiple files based on the date they were modified.
 - b) Select the **Is within last** option and specify a value in the field.

This option enables you to perform the operation on the files if they were created or modified within the number of days you have specified. For example, if you specify 7 in the field, the system performs the operation on the files if they were created or modified in the last 7 days.
 - c) Select the **Is between** option to specify a period.

This option enables you to specify a **Start date** and an **End date** for the period. For example, if you specify 01/01/19 as the start date and 01/31/19 as the end date of the period, the system performs the operation on the files if they were created or modified between this period.

Note: The **Start date** and **End date** are included in the period.

 - d) Select the **Is before** option and specify a value in the field.

This option enables you to perform the operation on the files if they were created or modified on or before the date you have specified.
 - e) Select the **On a date** option and specify a date in the field.

This option enables you to perform the operation on a file if it was created or modified on the date that you specified.
7. Click **Save**.

Using Rename action for file

Use the **Rename** action to rename a file. This action enables you to rename a file based on its size and the date it was created or modified.

To rename a file, follow these steps:

1. In the **Actions** palette, double-click or drag the **Rename** action from the **File** package.
2. From the **Source file** field select one of the following options:
 - **Specific**: Specify the name and location of the file.
 - For **Regex**: Specify the source folder path.

You can use a regular expression (regex) in your source file or folder path to support a pattern-based search. Select the regular expression either as a **String** or **Pattern** for each regular expression condition and enter the value.

For example, if want to copy, delete, rename or print multiple files from your source folder using pattern based search, use regular expressions either as a **String** and enter the value as `My_` for all file name starting with `My_` or as a **Pattern** such as `[a-z]{3}(.txt|xlsx)` to retrieve files that matches this pattern.

3. In the **New file name** field, specify a new name for the file.
4. Select the **Size** check box to rename a file based on its size.
 - a) Select one of the options from the list:
 - **Atleast**: Renames a file only if the file size is more than the size you have specified.
 - **Atmost**: Renames a file only if the file size is less than the size you have specified.
 - **Exact**: Renames a file only if the file size is the same as the size you have specified.
 - b) Specify a value in the **Size** field.
5. Select the **Date** check box to rename a file based on the date it was created or modified.
 - a) Select any of the following options from the list:
 - **Created**: Enables you to rename a file based on the date it was created.
 - **Modified**: Enables you to rename a file based on the date it was modified.
 - b) Select the **Is within last** option and specify a value in the field.

This option enables you to perform the operation on the file if it was created or modified within the number of days you have specified. For example, if you specify 7 in the field, the system performs the operation on the file if it was created or modified in the last 7 days.
 - c) Select the **Is between** option to specify a period.

This option enables you to specify a **Start date** and an **End date** for the period. For example, if you specify 01/01/19 as the start date and 01/31/19 as the end date of the period, the system performs the operation on the file if it was created or modified between this period.

Note: The **Start date** and **End date** are included in the period.

- d) Select the **Is before** option and specify a value in the field.

This option enables you to perform the operation on the file if it was created or modified on or before the date you have specified.

- e) Select the **On a date** option and specify a date in the field.
This option enables you to perform the operation on a file if it was created or modified on the date that you specified.

6. Click **Save**.

Create shortcut action

The Create shortcut action in the File package enables you to create a shortcut to a target file.

Settings

Creates a shortcut to a file at a user-specified location. The shortcut is dependent on the source file, so any changes you make to the source file will also apply to the shortcut.

- In the **Target location** field, specify the name and location.
- In the **Shortcut location** field, specify the name and location.

Note: Users with a valid role and required permission can create a shortcut to a file at a specified location.

Create symbolic link action

The Create a symbolic link action in the File package enables you to create a symbolic link to a target file.

Settings

Creates a symbolic link to a file at a user-specified location. The shortcut is dependent on the source file, so any changes you make to the source file will also apply to the shortcut.

- In the **Target location** field, specify the name and location.
- In the **Symbolic link location** field, specify the name and location.

Note: Users with only admin access can create a shortcut to a file at a specified location.

Folder package

Automate folder-related operations by using the actions available in the Folder package.

Actions in the Folder package

The Folder package includes the following actions:

Action	Description
Zip	See Zip action on page 2524.
Copy	See Copy action in Folder on page 2525.
Create	See .Create action in Folder on page 2526.
Unzip	See Unzip action on page 2526.
Delete	See Delete action in Folder on page 2526.
Create shortcut	See Create shortcut action on page 2528.
Open	See Open action in Folder on page 2528.
Rename	See Rename action in Folder on page 2528.
Create symbolic link	See Create symbolic link action on page 2529.

[Folder package updates](#) on page 846

Review the updates in released versions of the Folder package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Zip action

The **Zip** action enables you to compress files and folders into a .zip format.

- In the **Actions** palette, double-click or drag the **Zip** action from the **Folder** package.
- In the **Specify file(s)/folder(s) to compress** field, specify the location.
- In the **Specify file type(s) to compress** field, select one of the following options:
 - String**: Specify the file extension.
For example, you can specify .txt and .png to compress only text files and PNG images. The system compresses the entire folder if you do not specify any file type. You can also specify the name of a file to compress a specific file.
 - Regex**: Select the regular expression (regex) either as a **String** or **Pattern** for each regular expression condition and enter the value.
For example, you can use regular expressions either as a **String** and enter the value as `My_` for all file name starting with `My_` or as a **Pattern** such as `[a-z]{3}(.txt|xlsx)` to retrieve files that matches this pattern.
- In the **Specify destination filename and location** field, specify the zip file name and location.
- Select the **Update only if newer** check box to compress the files only if one or more files were updated after the last compression.
This option is useful when you are repeatedly compressing the same set of files and storing the output zip file with the same name at the same location. For example, you compress five PDF files from the `Reports` folder on a monthly basis and save the output zip file with the `Monthly Report` name in the `D:` drive. When this option is selected, the system compresses the files only if one or more PDF files are updated after the last compression.
- Select the **Delete original files** check box if you want to delete the original files after they are included in the zip file.

7. In the **Compression** list, select between **Normal**, **Fast**, and **Superfast** to specify the speed for compression.
8. Optional: In the **Password protection** field, click one of the following tabs to set a password:
 - **Credential**: To specify a stored password.
 - **Variable**: To set a variable for password.
 - **String**: To enter a password manually.
9. Click **Save**.

Copy action in Folder

The **Copy** action enables you to copy an existing folder into a specific location.

1. In the **Actions** palette, double-click or drag the **Copy** action from the **Folder** package.
2. In the **Source folder** field, specify the name and location.
3. In the **Destination folder** field, specify the folder name and location to save the copied folder.
4. Select the **Overwrite existing files/folders** check box to overwrite existing folders with the same name.

If this option is not enabled, the system appends a numeric value at the end of the file name. For example, if you save the `June_Quarter_report` file in a location that has a file with the same name, the system saves the file as `June_Quarter_report_(1).pdf`. The numeric value is incremented each time you save the file as long as the option is enabled.

5. Optional: Select the **Size** check box to copy a folder based on its size.
 - a) Use the drop-down menu to select one of the following options:
 - **Atleast**: Copies a folder only if the folder size is more than the size you have specified.
 - **Atmost**: Copies a folder only if the folder size is less than the size you have specified.
 - **Exact**: Copies a folder only if the folder size is the same as the size you have specified.
 - b) In the **Size (KB)** field, specify the folder size.
6. Optional: Select the **Date** check box to copy a folder based on the date.
 - a) Use the drop-down menu to select one of the following options:
 - **Created**: To copy a folder based on the date it was created.
 - **Modified**: To copy a folder based on the date it was modified.
 - b) Use the second drop-down menu to select one of the following additional options:
 - **Relative to runtime**: To set the date in regards to the bot runtime.
 - **Between two dates**: To specify the time period.

This option enables you to specify a **Start date** and an **End date** of the period. For example, if you specify 01/01/19 and 01/31/19 as the start date and end date, the system performs the operation on the folder if it was created or modified between these dates.

Note: The **Start date** and **End date** are included in the period.

- **On a date**: To specify a particular date.

This option enables you to set a specific date that a folders was created or modified.

- **Before a date:** To specify a date prior to which the folders were created.
For example, if you set the date as 07/28/20, folders created or modified before this date are selected

(Optional) Select the **Including date** check box if you want include the date you have specified for the **Before a date** option.

7. Click **Save**.

Create action in Folder

The **Create** action enables you to create a folder.

Settings

- In the **Folder** field, specify the name and location.
Folder names cannot include system actions or device references such as **AUX**, **CON**, **LPT**, **NUL**, and **PRN**.
- (Optional) Select the **Overwrite an existing folder** check box to overwrite an existing folder.

Note: If this option is not selected, the system appends the name of the new folder with a numeric value.

Unzip action

The **Unzip** action enables you to extract compressed content (files and folders) into a specific location from a **.zip** file.

1. In the **Actions** palette, double-click or drag the **Unzip** action from the **Folder** package.
2. In the **Zip file name with full path** field, specify the name and location.
3. In the **Extract to path** field, specify the location.
4. Select the **Replace existing file** check box to overwrite the file.
5. Optional: In the **Password to access zip file** field, click one of the following tabs to set a password:
 - **Credential:** To specify a stored password.
 - **Variable:** To set a variable for password.
 - **String:** To enter a password manually.

6. Click **Save**.

Delete action in Folder

The **Delete** action enables you to remove or delete folder from specific location.

1. In the **Actions** palette, double-click or drag the **Delete** action from the **Folder** package.
2. In the **Folder** field, specify the name and location.

3. Optional: Select the **Size** check box to delete a folder based on its size.
 - a) Use the drop-down menu to select of the following options:
 - **Atleast**: Deletes a folder only if the folder size is more than the size you have specified.
 - **Atmost**: Deletes a folder only if the folder size is less than the size you have specified.
 - **Exact**: Deletes a folder only if the folder size is the same as the size you have specified.
 - b) In the **Size** field, specify the folder size.

4. Optional: Select the **Date** check box to delete a folder based on the date it was created or modified.
 - a) Use the drop-down menu to select one of the following options:
 - **Created**: To delete a folder based on the date it was created.
 - **Modified**: To delete a folder based on the date it was modified.
 - b) Use the second drop-down menu to select one of the following additional options:
 - **Relative to runtime**: select this option and specify a value in the field. This option enables you to perform the operation on the file if it was created or modified within the number of days you have specified. For example, if you specify 7 in the field, the system performs the operation on the file if it was created or modified in the last 7 days.
 - **Between two dates**: To specify the time period.

This option enables you to specify a **Start date** and an **End date** of the period. For example, if you specify 01/01/19 and 01/31/19 as the start date and end date, the system performs the operation on the folder if it was created or modified between these dates.

Note: The **Start date** and **End date** are included in the period.

 - **On a date**: To specify a particular date.

This option enables you to set a specific date that a folders was created or modified.
 - **Before a date**: To specify a date prior to which the folders were created.

For example, if you set the date as 07/28/20, folders created or modified before this date are selected

(Optional) Select the **Including date** check box if you want include the date you have specified for the **Before a date** option.

5. Click **Save**.

Create shortcut action

The **Create shortcut** action enables you to create a shortcut of a folder at a specified location. As the folder shortcut is dependent on the source folder, any changes to the source folder is applied to the shortcut as well.

Settings

- Use the **Target location** field to select one of the following tabs:
 - **Desktop folder**: Click **Browse** to select the folder that you want to create a shortcut for.
 - **Variable**: Enter or paste the filepath of the folder that you want to create a shortcut for.
- Use the **Shortcut location** field to select one of the following tabs:
 - **Desktop folder**: Click **Browse** to select the folder where the folder shortcut must be created.
 - **Variable**: Enter the filepath where the folder shortcut must be created.

Note: Only the users with administrator role can create a shortcut of the source folder at a specified location.

Open action in Folder

The **Open** action enables you to open a folder from a specific location.

Settings

- Use the **Folder** field to specify the filepath of the folder you want to open.
- (Optional) Click the **Insert a value** icon to select a variable.

Rename action in Folder

The **Rename** action enables you to rename an existing folder.

1. In the **Actions** palette, double-click or drag the **Rename** action from the **Folder** package.
2. In the **Folder** field, specify the name and location.
3. In the **New folder name** field, specify a new name.
4. Select the **Size** check box to rename a folder based on its size.
 - a) Select any of the following options from the list:
 - **Atleast**: Renames a folder only if the folder size is more than the size you have specified.
 - **Atmost**: Renames a folder only if the folder size is less than the size you have specified.
 - **Exact**: Renames a folder only if the folder size is the same as the size you have specified.

- b) In the **Size** field, specify the folder size.
5. Select the **Date** check box to rename a folder based on the date it was created or modified.
- a) Select any of the following options from the list:
 - **Created**: To rename a folder based on the date it was created.
 - **Modified**: To rename a folder based on the date it was modified.
 - b) Use the second drop-down menu to select one of the following additional options:
 - **Relative to runtime**: To set the date in regards to the bot runtime.
 - **Between two dates**: To specify the time period.

This option enables you to specify a **Start date** and an **End date** of the period. For example, if you specify 01/01/19 and 01/31/19 as the start date and end date, the system performs the operation on the folder if it was created or modified between these dates.

Note: The **Start date** and **End date** are included in the period.

- **On a date**: To specify a particular date.
- **Before a date**: To specify a date prior to which the folders were created.

This option enables you to set a specific date that a folders was created or modified.

For example, if you set the date as 07/28/20, folders created or modified before this date are selected

(Optional) Select the **Including date** check box if you want include the date you have specified for the **Before a date** option.

6. Click **Save**.

Create symbolic link action

The **Create symbolic link** action enables you to create a symbolic link to a folder at a specified location. As this link is dependent on the source folder, any changes you make to the source folder is applied to the symbolic link.

Settings

- Use the **Target location** field to select one of the following tabs:
 - **Desktop folder**: Click **Browse** to select the folder that you want to create a shortcut for.
 - **Variable**: Enter or paste the filepath of the folder that you want to create a shortcut for.
- Use the **Symbolic link location** field to select one of the following tabs:
 - **Desktop folder**: Click **Browse** to select the folder where the folder shortcut must be created.
 - **Variable**: Enter the filepath where the folder shortcut must be created.

Note: Only the users with administrator role can create a shortcut of the source folder at a specified location.

FTP / SFTP package

Use the FTP / SFTP package to automate FTP / SFTP operations.

An FTP/SFTP server hosts the files to share. The client accesses, downloads, or uploads files to the server. The transfer of data between the client and server is done using a TCP/IP network, which is the standard protocol of communication over the internet.

- The following are some forms of authentication for an FTP server:
 - User credentials: Requires an FTP username and password.
 - Anonymous: This form of authentication is enabled on sites where files are available for public access and the users need not identify themselves to the server.
 - Key-based: SFTP authentication is usually done with a private and public key. The key pair is automatically generated by the computer. The private key is kept with the SFTP client and the corresponding public key with the SFTP server. When establishing a connection, the client shares the private key to be matched with the corresponding public key on the server.
- FTP can run in active or passive transfer mode.
 - In the active mode, the client informs the server about the port used for listening and starts listening for incoming data connections from the server.
 - In the passive mode, the client receives a server IP address and server port number from the server. The client opens a data connection to the server IP address and server port number that are received. Most organizations prefer the passive mode because it involves less or no alterations to the firewall settings.
- FTP supports binary and ASCII file transfer types:
 - Use the binary option when transferring executable files.
 - Use the ASCII option when transferring text files.

Before you start

Perform the following actions within the FTP / SFTP package.

1. Establish a connection with the FTP/SFTP server using the **Connect** action. When establishing a connection, associate the FTP/SFTP server details with a session name. Use the same session name for all corresponding actions.
2. Use the FTP/SFTP actions to automate a task. The actions enable you to perform following tasks:
 - Upload, download, delete, or rename files.
 - Upload, download, create, or delete folders.
 - Navigate to the parent folder or a specific folder.
3. After you have automated the tasks related to FTP / SFTP, terminate the connection to the server using the **Disconnect** action.

Note: SFTP with SSH1 protocol is no longer supported by SFTP.

View how to use FTP/SFTP connect action in the following video:

Actions in the FTP / SFTP package

The FTP / SFTP package includes the following actions:

Note: Regarding the use of a semicolon (;) in folder or file names, the following guidelines apply:

- You can use a semicolon (;) in the folder name for the following actions: **Delete** or **Create** folder
- You must not use a semicolon (;) in the folder or file name for other actions, such as the following: **Change folder**, **Delete files**, **Get files**, **Get folder**, **Put files**, **Put folders**, and **Rename files**

Action	Description
Change folder	See Change folder action on page 2532.
Connect	See Connect action on page 2532.
Create folder	See Create folder action on page 2534.
Delete folder	See Delete folder action on page 2534.
Delete files	See Delete files action on page 2535.
Disconnect	See Disconnect action on page 2535.
Get folders	See Get folders action on page 2535.
Get files	See Get files action on page 2536.
Put folders	See Put folders action on page 2536.
Put files	See Put files action on page 2537.
Rename files	See Rename files action on page 2537.

Related reference

[FTP/SFTP package updates](#) on page 847

Review the updates in released versions of the FTP / SFTP package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Change folder action

The **Change folder** action enables you to navigate to either a parent folder or a specific folder on an FTP/SFTP server.

Settings

- In the **Session name** field, enter the session name for FTP/SFTP server.
Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.
- Use the **Navigate to** field to select one of the following options:
 - **Go to parent folder**
 - **Specific folder**Ensure that you enter the complete folder path when you select the **Specific folder** option.

Connect action

The **Connect** action enables you to establish a connection with an FTP/SFTP server that you want to use for automating tasks. This must be the first action you use to automate an FTP/SFTP-related task.

Specify details of the FTP/SFTP server and associate it with a session name. Use the session name provided in this action in the other actions so that you do not have to provide details of the server in those actions.

1. Double-click or drag the **Connect** action in the **FTP/SFTP** node in the **Actions** palette.
2. In the **Server name** field, enter the FTP/SFTP server name.
3. In the **Port** field, enter the FTP/SFTP server port number.
4. Use the **Server type** field to select one of the following server type:

Server type	Steps
FTP	<p>Authentication type: You can choose to authenticate by either using Username & password or logging in as Anonymous. If you choose Username & password, complete the following fields:</p> <ul style="list-style-type: none"> In Username & password, select Credential, variable, or Insecure string. Enter values in the Username and Password fields. <p>If you choose to authenticate using the user credentials (username and password), insert a Credential Vault for enhanced security or enter the value directly in the Insecure string field.</p> <p>Transfer Mode: Select the transfer mode to be Active or Passive.</p> <p>Transfer type: Select the type to be either Binary or ASCII for transferring files between server and client.</p> <p>Optional: Enter the default directory path on the FTP server.</p>
FTP Secure	<p>Authentication type: You can choose to authenticate by either using Username & password or logging in as Anonymous. If you choose Username & password, complete the following fields:</p> <ul style="list-style-type: none"> In Username & password, select Credential, variable, or Insecure string. Enter values in the Username and Password fields. <p>If you choose to authenticate using the user credentials (username and password), insert a Credential Vault for enhanced security or enter the value directly in the Insecure string field.</p>
Secure FTP	<p>Choose Key and username, Key and credentials, or Credentials to authenticate the user:</p> <ul style="list-style-type: none"> Key and username: Select the Private Key File from Control Room file, Desktop file, or Variable. To enter the Username, select from the following options: Credential, variable, , and Insecure string. Key and credentials: Select the Private Key File from Control Room file, Desktop file, or Variable. To enter the Username, select from the following options: Credential, variable, , and Insecure string. <hr/> <ul style="list-style-type: none"> Note: Ensure that the SFTP server has a corresponding public key file. <hr/> <ul style="list-style-type: none"> Credentials: Select Credential, Variable, or Insecure string to enter the value in the Username and Password fields. <p>If you choose to authenticate using the user credentials (username and password), insert a Credential Vault for enhanced security or enter the value directly in the Insecure string field.</p>

- Optional: Select **Reconnect if connection fails** check box.
Use the following drop-down menus to select additional options while reconnecting:

- a) **Attempts:** Select the number of times the action must attempt to reconnect.
- b) **Time between attempts:** Select the time lapse between each attempt.

Note: If the connection fails due to incorrect credentials, the action will not attempt to reconnect.

6. Select any of the following tabs to create an FTP/SFTP session:
 - **Local session:** Specify a session name that can be used only in the current bot.
 - **Global session:** Specify a session name that can be used across multiple bots, such as parent bots and child bots.
 - **Variable:** Specify or create a session variable of subtype FTP/SFTP session.
7. Click **Save**.

Create folder action

The **Create folder** action enables you to create a folder on an FTP/SFTP server.

Settings

- In the **Session name** field, enter the session name for FTP/SFTP server.
Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.
- Use the **Remote folder** field to specify the filepath where the folder must be created on the FTP/SFTP server.

Note: The system encounters an error if a folder with the same name exists in the parent folder.

Delete folder action

The **Delete folder** action enables you to remove or delete a folder (including all the subfolders and files within it) from an FTP/SFTP server.

Settings

- In the **Session name** field, enter the session name for FTP/SFTP server.
Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.
- Use the **Remote folder** field to specify the filepath of the folder that must be deleted from the FTP/SFTP server.

Delete files action

The Delete files action enables you to remove or delete files from an FTP/SFTP server.

Settings

- In the **Session name** field, enter the session name for FTP/SFTP server.
Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.
- Use the **Remote files** field to specify the filepath of the file(s) that must be deleted from the FTP/SFTP server.

Disconnect action

The **Disconnect** action enables you to close or terminate an active connection to the FTP/SFTP server.

Settings

Select any of the following tabs to create an FTP/SFTP session:

- **Session name:** Enter or select a local or global session name variable.
- **Variable:** Enter or create a session variable of subtype FTP/SFTP session.

Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.

Get folders action

The **Get folders** action enables you to download a folder on an FTP/SFTP server into a client machine.

Settings

- In the **Session name** field, enter the session name for FTP/SFTP server.
Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.
- Use the **Remote folder** field to enter the filepath of the folders on the remote FTP/SFTP server that you want to download.
Specify filters using wildcard characters to download only specific types of files.
- Use the **Local folder** field to enter the location on your local device where you want to download the folders from the FTP/SFTP server.
- (Optional) Click the **Select date** drop-down menu to specify folders based on the date they were modified or created.

Get files action

The **Get files** action enables you to download files from a remote FTP/SFTP folder to a specific location on a client machine.

Note: When you use this action, it only downloads the files without removing them from the server.

Settings

- In the **Session name** field, enter the session name for FTP/SFTP server.
Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.
- Use the **Remote files** field to enter the filepath of the files on the remote FTP/SFTP server that you want to download.
Specify filters using wildcard characters to download only specific types of files.
- Use the **Local folder** field to enter the location of the client machine where you want to download the files from the FTP/SFTP server.
- Use the **Transfer Type** to select one of the following formats of the download files:
 - **Binary**
 - **ASCII**
- (Optional) Use the **Select date** drop-down menu to specify files based on the date they are modified or created.

Put folders action

The **Put folders** action enables you to upload a folder from a client machine to the FTP/SFTP server.

Settings

- In the **Session name** field, enter the session name for FTP/SFTP server.
Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.
- Use the **Local folder** field to enter the location of the client machine from where you want to upload folder to FTP/SFTP server.
Specify filters using wild card characters to restrict uploads to specific types of files.
- (Optional) Use the **File types** field to specify the type of files that must be included in the upload folder.

Put files action

The **Put files** action enables you to upload one or more files from a client machine to an FTP/SFTP server.

Settings

- In the **Session name** field, enter the session name for FTP/SFTP server.
Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.
- Use the **Local files** field to enter the location of the client machine from where you want to upload files to FTP/SFTP server.
Specify filters using wild card characters to restrict uploads to specific types of files.
- Use the **Transfer type** field to select one of the following upload format of the files:
 - **Binary**
 - **ASCII**

Rename files action

The **Rename files** action enables you to edit or change the name of files on an FTP/SFTP server.

Settings

- In the **Session name** field, enter the session name for FTP/SFTP server.
Use the same session name that you have provided when establishing a connection with the FTP/SFTP server using the **Connect** action.
- Use the **Remote file** field to specify the filepath of the file that you want to rename.
- Use the **New remote file** field to enter the new name of the file.

Fuzzy match package

Use the **Fuzzy match** action to compare the values of two strings or files for similarity. This action returns a decimal value; the closer the value to 1.0, the greater the similarity between the two strings.

Important: This is a beta package and is currently not available with the Automation 360 Enterprise and Cloud editions.

Use this action to automate the process of evaluating strings of data for similarity. For example, you have an automation sequence in which a bot extracts data from invoices, searches a database for the company record, and updates the record with data from the invoice. Use the **Fuzzy match** action to handle two possible scenarios:

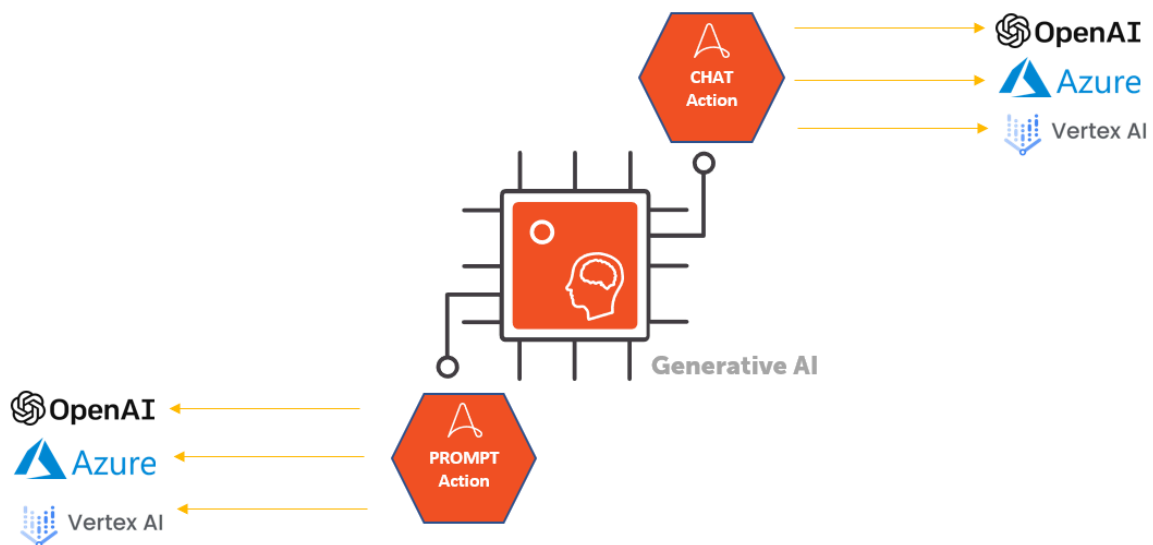

- A mistake occurs at the extraction step where a letter is incorrectly extracted. Instead of Apple, the bot extracts App1e, with a numerical one instead of the letter l.

- There is a small variation between the company name on the invoice and in the database. The invoice contains the company name Apple Inc, but the database has a record for the company name Apple.

Generative AI packages

Generative AI models use deep learning techniques, particularly generative models such as Large Language Models (LLMs). LLMs are deep learning models trained on massive datasets of text to generate human-like text or language-based content. With Automation Anywhere's Generative AI packages, you can select the model that best fits your automation needs.

Automation Anywhere provides prompt and chat (completion) actions for these generative AI vendors: Google, Microsoft, and OpenAI.

Google Vertex AI

Google Vertex AI is a cloud machine learning (ML) platform on which you can train and deploy generative AI based ML models and AI applications, and customize large language models (LLMs) to use in your AI-powered applications. Each foundation model is fine-tuned for specific use cases.

Automation Anywhere's Google package leverages Google Vertex AI features to build automations using the hosted model endpoints.

Watch the following videos that illustrates a Vertex AI use case:

Google Connect action

Google Cloud's Generative AI offers a range of benefits to organizations using Google Cloud Platform (GCP) for different use cases and purposes. You can connect to a Google Cloud Platform (GCP) instance using the Google Connect action. The GCP manages access to your Vertex AI instance.

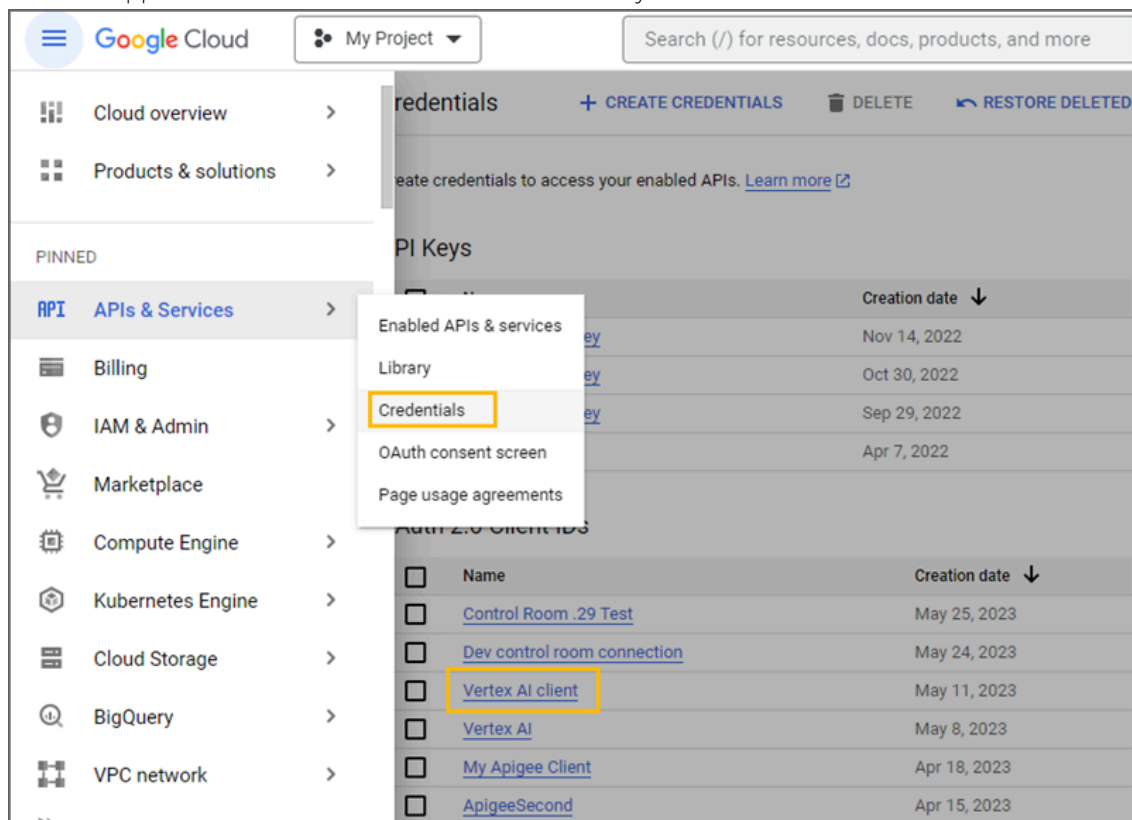

- Create a GCP account ([GCP Cloud](#)) and create a GCloud project.

- Log in to your GCloud account at [Google Cloud Project](#) and create a project. If you already have access to a project, you can view it here.
- Create an OAuth 2.0 Client ID. A client ID is used to identify a single application to Google's OAuth Servers. For more details, see [Google connect](#).

You can connect to a GCP instance using the **Google Connect** action from Automation 360. To connect to a GCP, you can use one of the following connection methods:

- **User Account:** Enter the GCloud account credentials to establish a connection.
- **Service Account:** Enter the GCloud service account key to authenticate between servers using the certificate. To create a service account key, see [Creating a service account](#).
- **Control Room OAuth Connection:** Select the previously configured OAuth connection in your Automation Anywhere Control Room.

1. Open the [Google Cloud console](#).
2. At the top-left, click **Menu > APIs & Services > Credentials**.
3. Click an application under OAuth 2.0 Client IDs that you want to connect.

4. Copy the values from the **Client ID**, **Client secret**, and **URI** fields.
5. Create a new bot. For more details, see [Create your first bot](#) on page 1429.
6. In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Generative AI > Google**, drag **Connect**, and place it in the canvas.
7. Connect to the GCP using one of these methods: User Account, Service Account, or Control Room OAuth.
Connect using User Account

To connect using the User Account method:

- a) In the **User Email Address** field, enter the email address that is used to log in to the GCloud account.
- b) In the **Client ID** field, paste the **Client ID** copied from the GCloud. This example uses **Insecure string** (for stronger security, you can use **Credential** or **Variable**).

Note: You can use one of the following options to specify the **User Email Address/Client ID/Client secret/Redirect URI**:

- **Credential:** To implement stronger security, you can use values in the Credential Vault that contains information about the User Email Address/Client ID/Client secret/Redirect URI.
- **Variable:** To implement stronger security, you can use a credential variable that contains information about the User Email Address/Client ID/Client secret/Redirect URI..
- **Insecure string:** Enables you to enter the User Email Address/Client ID/Client secret/Redirect URI.

-
- c) In the **Client Secret** field, paste the **Client Secret** copied from the GCloud.
 - d) In the **Redirect URI** field, enter the redirect URI from the GCloud account.
 - e) Enter **Default** as the session name.

Connect using Service Account

To connect using the Service Account method:

- a) In the **Service Account Key** field, enter the GCloud service account key. This example uses **Insecure string** (for stronger security, you can use **Credential** or **Variable**).
- b) In the **Create Vertex AI session** field, the session name is displayed as **Default**

Note: If you do not have access to generate and retrieve the **Service Account Key**, contact your Google Cloud Admin.

Connect using Control Room OAuth connection

To connect using the Control Room OAuth, select an available OAuth connection. For information on setting up an OAuth connection, see [Create OAuth connection](#) on page 1827.

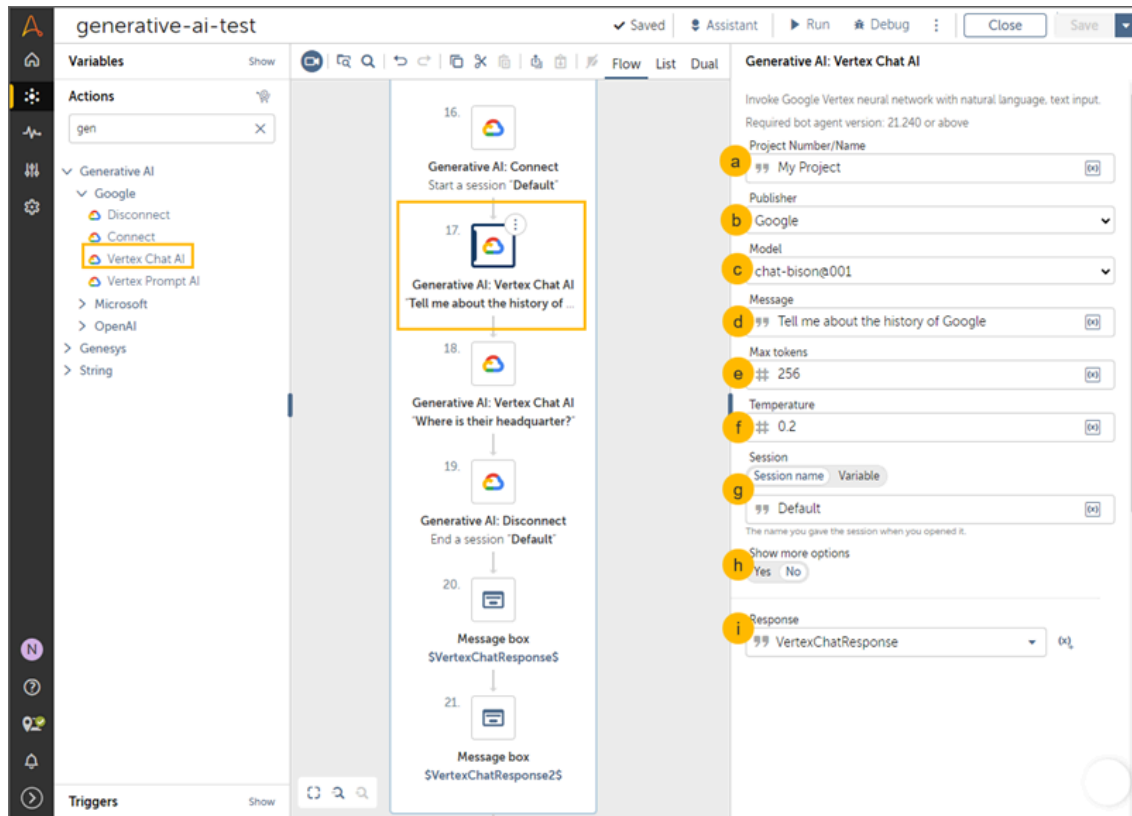

Vertex Chat AI action

Generative AI support on Vertex AI gives you access to Google's large generative AI models. The Vertex Chat AI action uses Google's Vertex AI completion model API for interacting with the `chat-bison@001`, `codechat-bison@001` model, or a custom model. It generates text in a conversational format.

- You must have the Bot creator role to use the Vertex Chat AI action in a bot.
- Ensure that you have the necessary credentials to send a request. For more information on acquiring the credentials, see [Google Connect action](#) on page 2538.

This example shows how to send a natural language message using the Google Vertex AI action and get an appropriate response.

1. In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Generative AI > Google**, drag **Vertex Chat AI**, and place it in the canvas.
2. Enter or select the following fields:

- a) Enter the Project Number/Name. This is the unique Project ID from the GCP. For information on Project ID, see [Google Cloud Project's Project ID](#).
- b) Click Publisher drop-down and select Google; or select 3rd Party to enter a third-party publisher.
- c) Click the Model drop-down and select a model with which to communicate.
 - chat-bison: A model fine-tuned for multi-turn conversation use cases.
 - codechat-bison: A model fine-tuned for chatbot conversations that help answer code-related questions.
 - Custom: Select Custom to add a custom model.
- d) Enter a chat **Message** to use by the model to generate a response.

Note: The chat action will retain the result of the previous chat action within the same session. If you call chat actions consecutively, the model can understand the subsequent messages and relate them to the previous message.

- e) Enter the maximum number of tokens to generate. By default, if you do not enter a value, then the maximum number of tokens generated is automatically set to keep it within

the maximum context length of the selected model by considering the length of the generated response.

- f) Enter a **Temperature**. This value refers to the randomness of the response. As the temperature approaches zero, the response becomes more focused and deterministic. The higher the value, the more random is the response.
 - g) Enter Default as the session name to limit the session to the current session.
 - h) To manage the optional parameters, click the **Show more options** and select **Yes**. If you select Yes, you can add other parameters such as: **Context**, **Examples**, **Top K**, and **Top P**. For information about these optional parameters, see [Learn Models](#).
 - i) Save the response to a variable. In this example, the response is saved to VertexChatResponse.
3. Click **Run** to start the bot. You can read the value of the field by printing the response in a Message box action. In this example, VertexChatResponse prints the response. You can add additional chat requests to get additional responses.

Vertex Prompt AI action

The Vertex Prompt AI action uses of the Vertex AI's PaLM API that enables you to unlock generative AI capabilities. This API provides access to the model's text-in and text-out interfaces. You can provide an input prompt containing the English text command and the model generates a text completion.

- You must have the Bot creator role to use the Vertex Prompt AI action in a bot.
- Ensure that you have the necessary credentials to send a request. For information on acquiring the credentials, see [Google Connect action](#) on page 2538.

This example shows how to send a natural language prompt using the Google Vertex Prompt AI action and to get an appropriate response.

1. In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Generative AI > Google**, drag **Vertex Prompt AI**, and place it in the canvas.
2. Enter or select the following fields:

The screenshot displays the Google Vertex AI interface for configuring a generative AI workflow. The workflow is composed of four steps:

- Start**: Initiates the process.
- Generative AI: Connect**: Starts a session named "Default".
- Generative AI: Vertex Prompt AI**: Sends a prompt "Tell me about the eiffel tower". This step is highlighted with a yellow box and labeled '2'.
- Generative AI: Disconnect**: Ends the session named "Default".

The right-hand panel, titled "Generative AI: Vertex Prompt AI", contains the following configuration options:

- a)** Project Number/Name: My Project
- b)** Publisher: Google
- c)** Model: text-bison@001
- d)** Prompt: Tell me about the eiffel tower
- e)** Max tokens: 256
- f)** Temperature: 0.2
- g)** Session name: Default
- h)** Show more options: No
- i)** Response: google-vertex-prompt-response

- Enter the Project Number/Name. This is the unique Project ID from the GCP. For more information on Project ID, see [Google Cloud Project's Project ID](#).
- Click Publisher drop-down and select Google; or select 3rd Party to enter a third-party publisher.
- Click the Model drop-down and select a model to send prompt.
 - code-bison@001: A model fine-tuned to generate code based on a natural language description of the desired code. For example, it can generate a unit test for a function.
 - code-gecko@001: A model fine-tuned to suggest code completion based on the context in code that is written.
 - text-bison@001: A model fine-tuned to follow natural language instructions and is suitable for a variety of language tasks.
 - text-bison (latest): The latest version of the text-bison.
 - Custom: Select Custom to add a custom model.

Note:

- Bison: Best value in terms of capability and cost.
- Gecko: Smallest and lowest cost model for simple tasks.

- Enter a **Prompt** to use by the model to generate a response.

- e) Enter the maximum number of tokens to generate. By default, if you do not enter a value, then the maximum number of tokens generated is automatically set to keep it within the maximum context length of the selected model by considering the length of the generated response.
 - f) Enter a **Temperature**. This value refers to the randomness of the response. As the temperature approaches zero, the response becomes more focused and deterministic. The higher the value, the more random is the response.
 - g) Enter Default as the session name to limit the session to the current session.
 - h) To manage the optional parameters, click the **Show more options** and select **Yes**. If you select Yes, you can add other parameters such as: **Top K** and **Top P**. For information about these optional parameters, see [Learn Models](#).
 - i) Save the response to a variable. In this example, the response is saved to google-vertex_prompt-response.
3. Click **Run** to start the bot. You can read the value of the field by printing the response in a Message box action. In this example, google-vertex_prompt-response prints the response.

Google Disconnect action

You can disconnect from your Google Cloud Platform (GCP) instance and clear the session using the Disconnect action.

1. In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Generative AI** > **Google**, drag **Disconnect**, and place it in the canvas at the end of your bot logic.
2. Enter the session name.
3. After the bot runs, your Generative AI instance is disconnected.

Microsoft Azure OpenAI

Microsoft Azure OpenAI enables generative AI capabilities by training on massive amounts of data to learn the patterns and relationships between words, phrases and sentences. It offers industry-leading coding and language AI models that you can fine-tune to your specific needs for a variety of use cases.

Azure OpenAI service provides REST API access to OpenAI's powerful language models including the GPT-3, Codex, and Embeddings model series. You can use Automation Anywhere's Microsoft Azure OpenAI package to connect with the Azure OpenAI REST APIs to build generative AI based automations that respond to your general natural language queries.

Configuring the Azure OpenAI

You can configure the Azure OpenAI to extract the credentials required by the Automation Anywhere Control Room to authenticate and communicate with the Azure OpenAI.

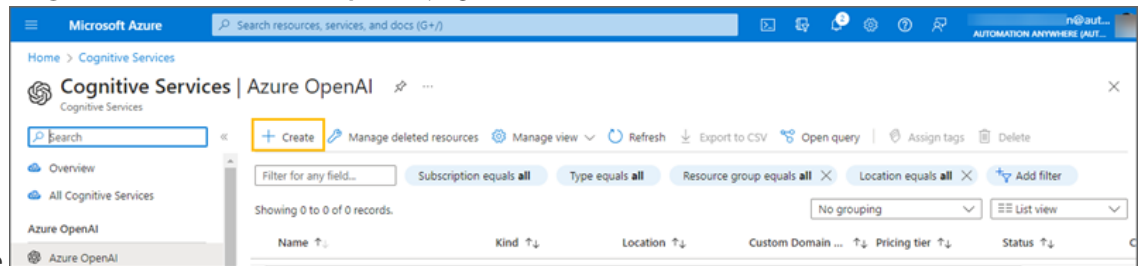

Create a developer account in Azure OpenAI to copy the login credentials. For information on OpenAI, see the [Azure OpenAI Service Documentation](#).

1. Log in to the [Azure portal](#) and search for **Azure**

OpenAI.

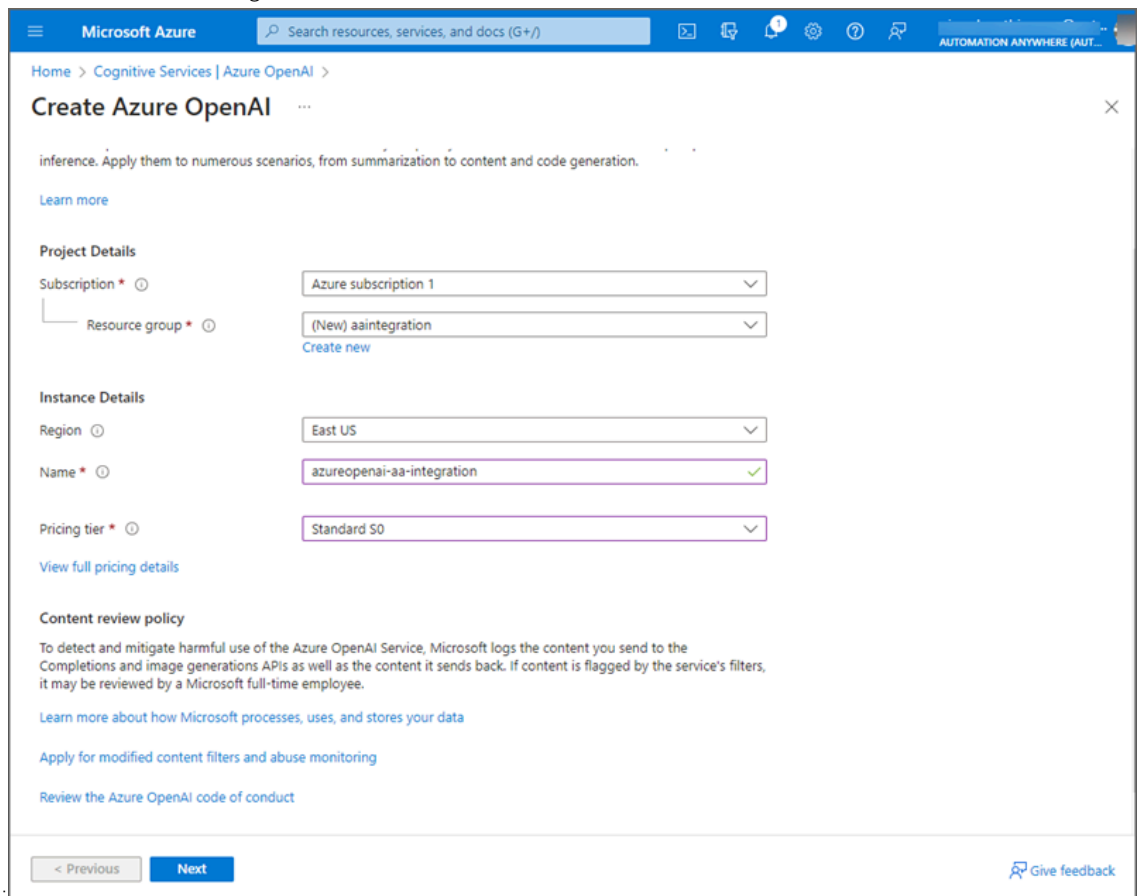

2. On the **Cognitive Services Azure OpenAI** page, click

Create.

The Create Azure OpenAI page appears.

3. Enter or select the following

details:

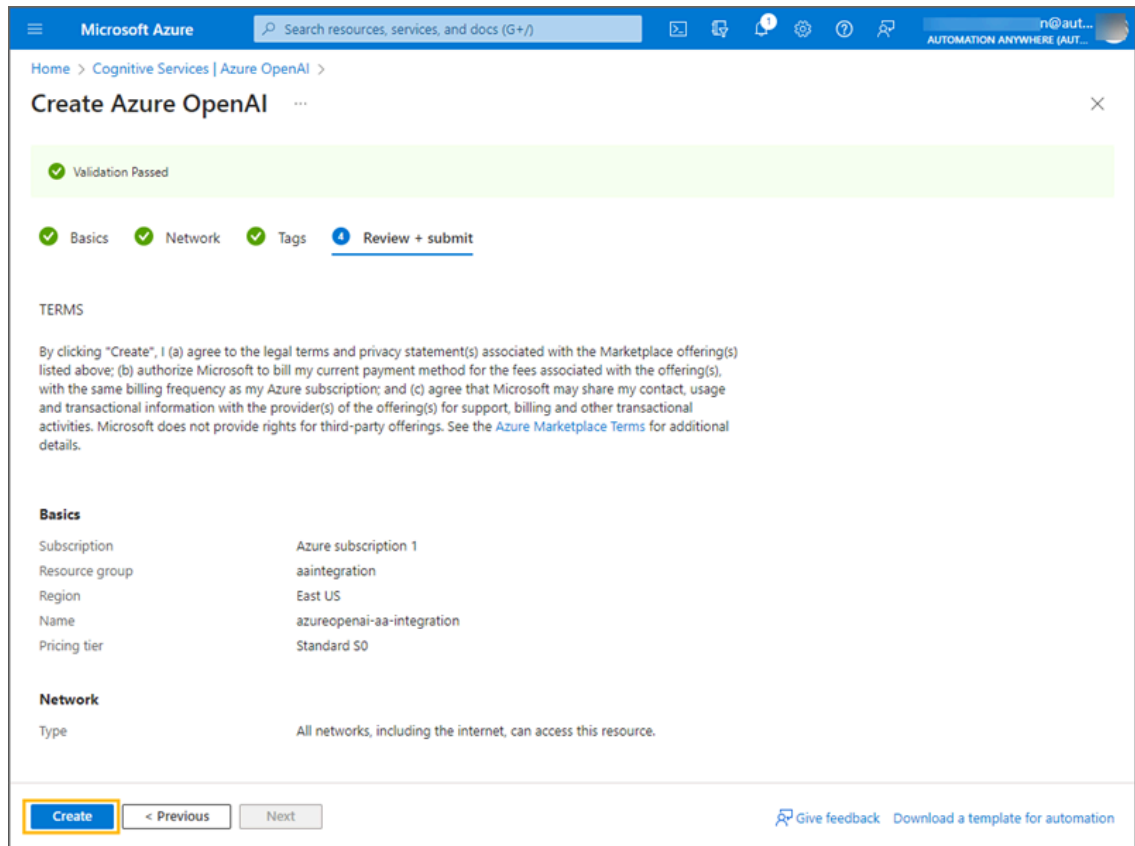

- a) Create or select an existing **Resource group**. A resource group is a collection of resources that share the same lifecycle, permissions, and policies.
- b) Select the Azure region for your specific location. For example, East US.

- c) Enter the **Name** of your resource. This will also be your custom domain name in your endpoint.

Note: Your resource name can include alphanumeric characters and hyphens, but cannot start or end with a hyphen.

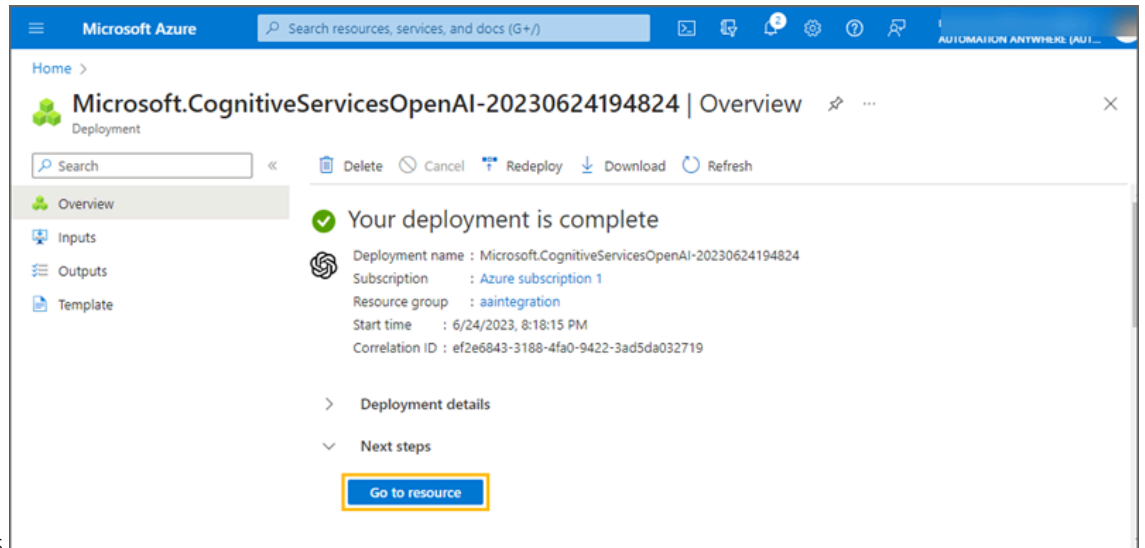

- d) Select a **Pricing tier**.

4. Click **Next**.
5. On the **Create Azure OpenAI, Network** page, select **All networks, including the internet, can access this resource**.
6. Click **Next**.
7. On the **Create Azure OpenAI, Tags** page, you can create tags. For more information, see [Using tags to organize Azure resources and management hierarchy](#). No tags are created in this example.
8. Click **Next**.
9. On the **Create Azure OpenAI, Review+Submit** page, review all the information and click **Create**.

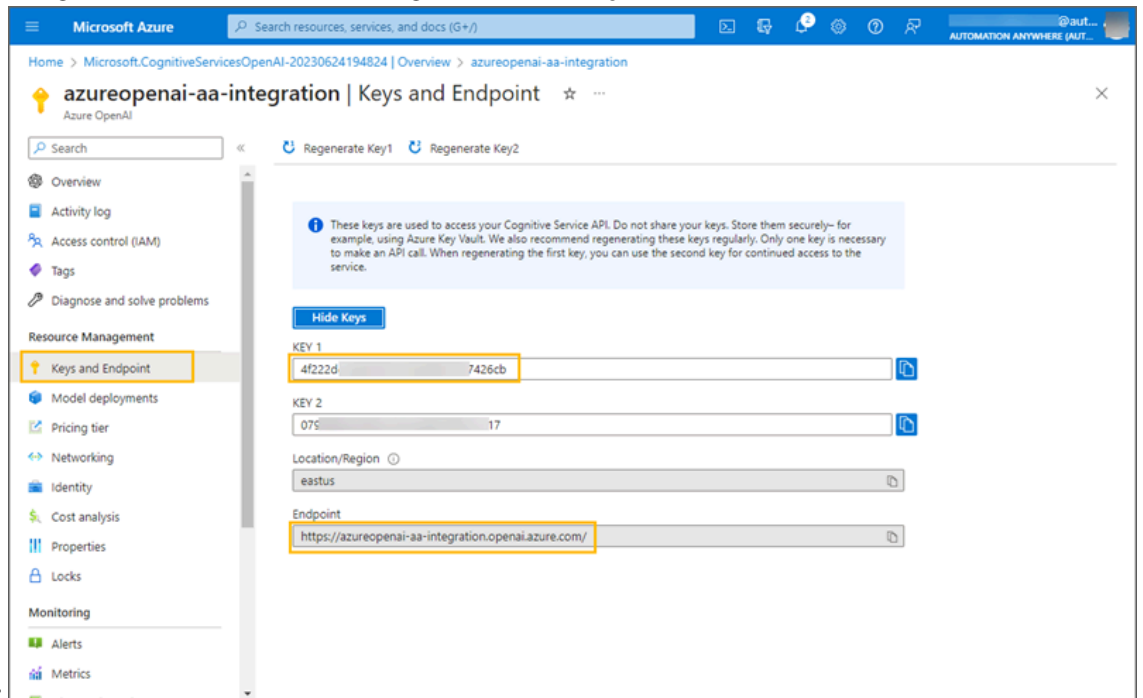

You can view status messages such as initiating deployment and submitting deployment. After the Azure OpenAI service is successfully initialized and deployed, the **Your deployment is complete** message displays at the top of the page.

- Click **Go to Resource** to view the app

details.

- In the left navigation, under Resource Management, click **Keys and**

Endpoint.

- Click **Show Keys**.
 - Copy the **API Key** (in the first key field) and the **Endpoint**.
 - Click **Model deployments** and then click **Manage Deployments** to navigate to the Azure OpenAI studio where you can create and deploy models. For more information on deploying a model, see [Deploy a model](#).
 - Copy the Model you deployed.
- You should have all the credentials to communicate with the Azure OpenAI.
 - Copy the **API Key**, **Endpoint**, and **Model** to use in the [Azure Chat AI action](#) on page 2548 and [Azure Prompt AI action](#) on page 2549.

Azure Chat AI action

The Azure Chat AI action uses the Azure AI's chat endpoint, which is a dedicated API used to interact with the ChatGPT and GPT-4 models (popular generative AI models). It takes input in a chat-like format and returns a message in the chat.

- You must have the Bot creator role to use the OpenAI Chat AI action in a bot.
- Ensure that you have the necessary credentials (Endpoint, Deployment ID, and API Key) to send a request. For information on how to acquire the credentials, see [Configuring the Azure OpenAI](#) on page 2544.

This example shows how to send a natural language message using the Microsoft Azure Chat AI action and get an appropriate response.

- In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Generative AI** > **Microsoft**, drag **Azure Chat AI**, and place it in the canvas.
- Enter or select the following fields:

- Enter the Microsoft Azure **Endpoint**.
- Enter the **Deployment ID**.
- Enter the **API Key**. For information on how to obtain the Endpoint, Deployment ID, and API Key, see [Configuring the Azure OpenAI](#) on page 2544. To specify the **API Key**, select one of the following options:
 - Credential**: To implement stronger security, you can use values available in the Credential Vault that contains the API Key. For more information on creating a credential, see [Set up lockers and credentials in Credential Vault](#) on page 1797.

- **Variable:** To implement stronger security, you can use a credential variable that contains the API Key. For more information on creating a variable, see [Credentials and credential variables in the Bot editor](#) on page 2254.
- **Insecure string:** Enables you to manually enter the API Key for Microsoft Azure.

d) Enter a chat **Message** to use by the model to generate a response.

Note: The chat action will retain the result of the previous chat action within the same session. If you call chat actions consecutively, the model can understand the subsequent messages and relate them to the previous message.

- e) Enter the maximum number of tokens to generate. By default, if you do not enter a value, then the maximum number of tokens generated is automatically set to keep it within the maximum context length of the selected model by considering the length of the generated response.
- f) Enter a **Temperature**. This value refers to the randomness of the response. As the temperature approaches zero, the response becomes more focused and deterministic. The higher the value, the more random is the response.
- g) Enter Default as the session name to limit the session to the current session.
- h) To manage the optional parameters, click the **Show more options** and select **Yes**. If you select Yes, you can add other parameters such as: **Top P**, **Stop**, **Presence Penalty**, **Frequency Penalty**, and **User**. For information about these optional parameters, see [Azure Open AI chat completions](#).
- i) Save the response to a variable. In this example, in the response is saved to azure-ai-response.

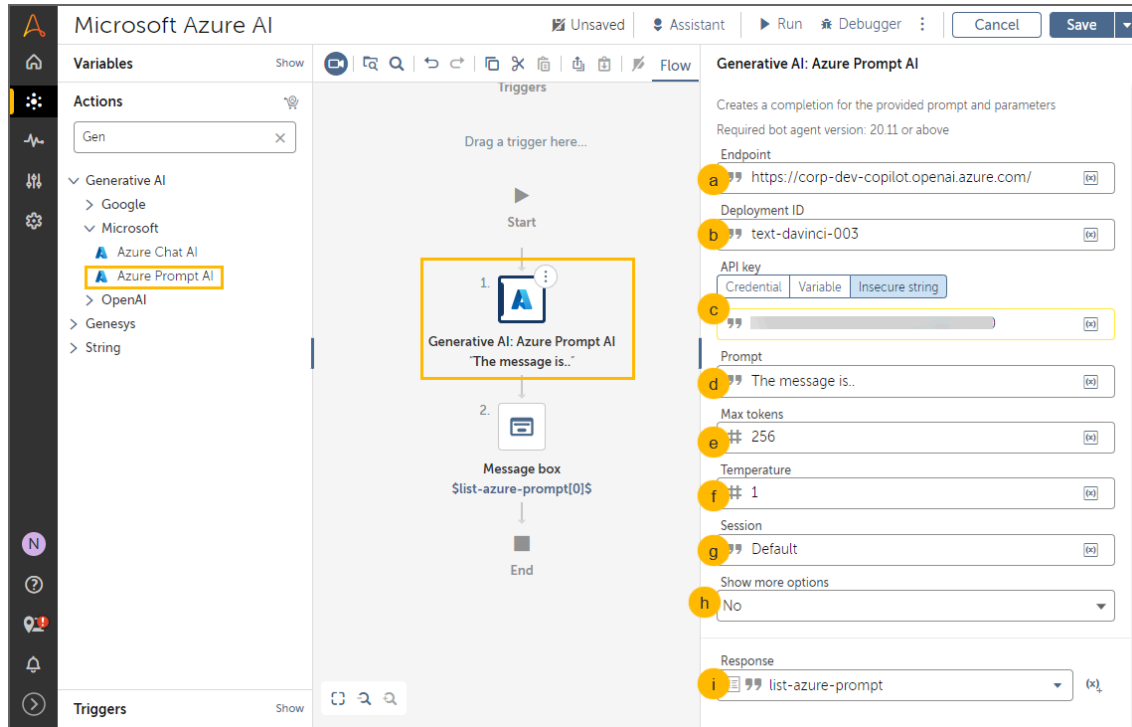

3. Click **Run** to start the bot. You can read the value of the field by printing the response in a Message box action. In this example, azure-ai-response prints the response.

Azure Prompt AI action

The Azure Prompt AI action uses the Azure AI's completions endpoint that enables you to unlock generative AI capabilities. This API provides access to the model's text-in and text-out interface. You can provide an input prompt containing the natural language text command and the model will generate a text completion.

This example shows how to send a natural language prompt using the Microsoft Azure Prompt AI action and get an appropriate response.

1. In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Generative AI > Microsoft**, drag **Azure Prompt AI**, and place it in the canvas.
2. Enter or select the following fields:

- a) Enter the Microsoft Azure **Endpoint**.
- b) Enter the **Deployment ID**. The Deployment ID is linked to the large language model (LLM) you want to use for your prompt.
- c) Enter the **API Key**. For information on how to acquire the Endpoint, Deployment ID, and API Key, see [Configuring the Azure OpenAI](#) on page 2544. To specify the **API Key**, select one of the following options:
 - **Credential**: To implement stronger security, you can use values available in the Credential Vault that contains the API Key. For information on creating a credential, see [Set up lockers and credentials in Credential Vault](#) on page 1797.
 - **Variable**: To implement stronger security, you can use a credential variable that contains the API Key. For information on creating a variable, see [Credentials and credential variables in the Bot editor](#) on page 2254.
 - **Insecure string**: Enables you to manually enter the API Key for Microsoft Azure.
- d) Enter a **Prompt** to use by the model to generate a response.
- e) Enter the maximum number of tokens to generate. By default, if you do not enter a value, then the maximum number of tokens generated is automatically set to keep it within the maximum context length of the selected model by considering the length of the generated response.
- f) Enter a **Temperature**. This value refers to the randomness of the response. As the temperature approaches zero, the response becomes more focused and deterministic. The higher the value, the more random is the response.
- g) Enter Default as the session name to limit the session to the current session.
- h) To manage the optional parameters, click the **Show more options** and select **Yes**, if you want to manage the optional parameters. If you select Yes, you can add other parameters such as: **API version, Suffix, Top P, N, Logprobs, Echo, Stop, Presence**

Penalty, Frequency Penalty, Best of, Logit bias, and User. For more information about these optional parameters, see [Azure Open AI completions](#).

- i) Save the response to a variable. In this example, the response is saved to `list_azure_prompt`.
3. Click **Run** to start the bot. The output of a prompt is a list where you can set **N** as the optional parameter, generate multiple prompts for each input. To read the response of the prompt, you can print the response in a Message box action. In this example, the first element of the list `list_azure_prompt[0]` prints the response because N is set to 1.

OpenAI

OpenAI is an artificial intelligence research laboratory used to research and develop artificial general intelligence (AGI). OpenAI combines machine learning algorithms and deep learning techniques to train its generative AI systems. It enables to unlock powerful generative AI capabilities by training on massive amounts of data.

Automation Anywhere's OpenAI package connects seamlessly with OpenAI APIs to build automations using the OpenAI model, including Generative Pre-trained Transformer 3.5 (GPT-3.5).

Watch the following videos that illustrates an Open AI use case:

To use a GPT with OpenAI API, you send a request containing the inputs and your API key, and then receive a response containing the output from the model. The `Chat Completions API` and `Completions API` of OpenAI are both supported using the OpenAI Chat AI action and OpenAI Prompt AI action. The difference between these APIs derives from the underlying GPT models. To use either of these APIs, you will need to create an OpenAI API key.

Create an OpenAI API Key

To create an OpenAI API key:

1. Create an account at: [Create OpenAI Account](#).
2. Log in to your OpenAI account.
3. Access this link: [API-Keys](#).
4. Click **Create new secret key**.
5. Copy the secret to your clipboard

OpenAI Chat AI action

The OpenAI Chat AI action mimics ChatGPT (a subset of generative AI) by taking a message as input and returning a model-generated message as output.

- You must have the Bot creator role to use the OpenAI Chat AI action in a bot.
- Ensure that you have the necessary credentials (API Key) to send a request.

This example shows how to send a natural language message using the OpenAI Chat AI action and get an appropriate response.

1. In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Generative AI > OpenAI**, drag **OpenAI Chat AI**, and place it in the canvas.

2. Enter or select the following fields:

- a) Enter the OpenAI API Key. For information on how to obtain the API Key, see [OpenAI](#) on page 2551. To specify the **API Key**, select one of the following options:
- **Credential:** Enables you to use a value available in the Credential Vault that contains the API Key. For more information on creating a credential, see [Set up lockers and credentials in Credential Vault](#) on page 1797.
 - **Variable:** Enables you to use a credential variable that contains API Key. For more information on creating a variable, see [Credentials and credential variables in the Bot editor](#) on page 2254.
 - **Insecure string:** Enables you to manually enter the API Key for OpenAI.
- b) Select a large language model (LLM) to use for your chat from the list of models listed in the dropdown. The model type defaults to **gpt-3.5-turbo**. You can also select the following models: **gpt-4**, **gpt-4-32k**, and **custom** to add your own custom model.
- c) Enter a chat **Message** to use by the model to generate a response.

Note: The chat action will retain the result of the previous chat action within the same session. If you call chat actions consecutively, the model can understand the subsequent messages and relate them to the previous message.

- d) Enter the maximum number of tokens to generate. By default, if you do not enter a value, then the maximum number of tokens generated is automatically set to keep it within the maximum context length of the selected model by considering the length of generated response.

- e) Enter a **Temperature**. This value refers to the randomness of the response. As the temperature approaches zero, it makes the response more focused and deterministic. The higher the value, the more random is the response.
 - f) Enter Default as the session name to confine to the current session.
 - g) To manage the optional parameters, click **Show more options** and select **Yes**. If you select Yes, you can add other parameters such as: **Top P**, **Stop**, **Presence Penalty**, **Frequency Penalty**, and **User**. For information about these optional parameters, see [OpenAI Chat Create](#).
 - h) Save the response to a variable. In this example, the response is saved to STR_OpenAI_ChatResponse.
3. Click **Run** to start the bot. You can read the value of the field by printing the response in a Message box action. In this example, STR_OpenAI_ChatResponse prints the response.

OpenAI Prompt AI action

The OpenAI Prompt AI action mimics OpenAI's completions, by taking a prompt as input and returning a model-generated one or more predicted completions.

- You must have the Bot creator role to use the OpenAI Prompt AI action in a bot.
- Ensure you have the necessary credentials (API Key) to send a request.

This example shows how to send a natural language prompt using the OpenAI Prompt AI action and get an appropriate response.

1. In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Generative AI > OpenAI**, drag **OpenAI Prompt AI**, and place it in the canvas.
2. Enter or select the following fields:

The screenshot displays the Automation Anywhere interface for configuring an OpenAI Prompt AI action. The interface is divided into three main sections: a left sidebar with navigation options, a central workflow canvas, and a right-hand configuration panel.

- Left Sidebar:** Contains 'Variables', 'Actions', and 'Triggers' sections. Under 'Actions', 'OpenAI Prompt AI' is selected and highlighted with a yellow box.
- Central Canvas:** Shows a workflow diagram starting with a 'Start' trigger, followed by a 'Generative AI: OpenAI Prompt AI' action (labeled '1') and a 'Message box' action (labeled '2') with the output variable '\$list_OpenAI_prompt[0]\$. The 'Generative AI' action is highlighted with a yellow box.
- Right Panel:** Displays configuration options for 'Generative AI: OpenAI Prompt AI'.
 - a:** API key selection options: Credential, Variable, Insecure string.
 - b:** Model selection dropdown, currently set to 'text-davinci-003'.
 - c:** Prompt text input field, currently containing 'Message is'.
 - d:** Max tokens input field, currently set to '256'.
 - e:** Temperature input field, currently set to '1'.
 - f:** Session input field, currently set to 'Default'.
 - g:** Show more options dropdown, currently set to 'No'.
 - h:** Output variable dropdown, currently set to 'list_OpenAI_prompt'.

- a) Enter the OpenAI API Key. For information on how to obtain the API Key, see [OpenAI](#) on page 2551. To specify the **API Key**, select one of the following options:
 - **Credential:** Enables you to use a value available in the Credential Vault that contains the API Key. For more information on creating a credential, see [Set up lockers and credentials in Credential Vault](#) on page 1797.
 - **Variable:** Enables you to use a credential variable that contains the API Key. For more information on creating a variable, see [Credentials and credential variables in the Bot editor](#) on page 2254.
 - **Insecure string:** Enables you to manually enter the API Key for OpenAI.
- b) Select a large language model (LLM) to use for your prompt from models listed in the drop-down. The model type defaults to **text-davinci-003**. You can also select the following models: **text-davinci-003**, **text-davinci-002**, **davinci**, **text-curie-001**, **curie**, **text-babbage-001**, **babbage**, **text-ada-001**, **ada**, and **custom** to add your own custom model.
- c) Enter a **Prompt** to use by the model to generate a response.
- d) Enter the maximum number of tokens to generate. By default, if you do not enter a value, then the maximum number of tokens generated is automatically set to keep it within the maximum context length of the selected model by considering the length of generated response.

- e) Enter a **Temperature**. This value refers to the randomness of the response. As the temperature approaches zero, it makes the response more focused and deterministic. The higher the value, the more random is the response.
 - f) Enter Default as the session name to confine to the current session.
 - g) To manage the optional parameters, click the **Show more options** and select **Yes**. If you select Yes, you can add other parameters such as: **Suffix, Top P, N, Logprobs, Echo, Stop, Presence Penalty, Frequency Penalty, Best of, Logit bias, and User**. For information about these optional parameters, see [Open AI completions](#).
 - h) Save the response to a variable. In this example, the response is saved to list_OpenAI_prompt.
3. Click **Run** to start the bot. The output of a prompt is a list where you can set **N** as the optional parameter, generate multiple prompts for each input. To read the response of the prompt, you can print the response in a Message box action. In this example, the first element of the list list_OpenAI_prompt[0] prints the response because N is set to 1.

Genesys package

Automate the repetitive tasks related to onboarding and updating the details of contacts by using the actions in the Genesys package.

Intended use

The actions in the Genesys package are intended for use with the Automation Anywhere for Genesys integration. Currently, data cannot be passed directly from the integration to Genesys. These actions require a source data file to call from. You can then choose to manipulate the data by using variables or another worksheet before passing the final changes back to the Genesys source file. The actions included in this package are intended to offer automated solutions for common tasks.

Actions in the Genesys package

Use the following actions in the Genesys package to automate common onboarding and updating tasks.

Action	Description
Authentication	Perform the required authentication for API connection. Authentication action in Genesys on page 2556
Conversation	Call details of a conversation in Genesys. Conversation action in Genesys on page 2557
Division	Perform actions related to division details, such as adding and removing roles to a division. Division palette on page 2558
External contact	Perform actions such as adding and updating contact details. External contact palette on page 2561

Action	Description
Group	Perform actions such as adding and deleting members from a group. Group palette on page 2563
Language	Perform actions such as adding, listing, and removing routing languages. Language palette on page 2566
External organization	Perform actions such as creating, updating, and deleting organizations. External organization palette on page 2569
Phone	Perform actions such as assigning, creating, and removing phone records. Phone palette on page 2571
Queues	Perform actions such as adding and removing selections from queues. Queues palette on page 2575
Role	Perform actions such as adding, setting, and removing roles for users. Role palette on page 2577
Skill	Perform actions such as adding, replacing, and removing skills. Skill palette on page 2581
User	Perform actions such as creating, deleting, and getting users. User palette on page 2585

Authentication action in Genesys

The **OAuth authenticate** action calls your Genesys credential token and is required for the bot to connect with the API.

You can use different connection methods to connect to Genesys:

- **OAuth2 - Client Credentials:** Use this connection method by providing the Genesys credentials.
- **Control room OAuth connection:** Use this connection method by creating an OAuth connection and storing it in the Control Room.

Procedure

1. Log in to the Control Room.
2. Create a new bot or edit an existing bot. For more details, see [Create your first bot](#) on page 1429.
3. From the Actions pane, select **Genesys > Authentication > OAuth authenticate** and place it under the **Start** of the bot flow.
4. In the **Authentication Type** field, select the authentication method from the drop-down list.
5. To connect using **OAuth2 - Client Credentials**, complete the following steps:
 - a) Enter the URL for the **Genesys cloud environment**.
 - b) Select how you would like your credentials passed.
 - Use **Credential** to pick a preconfigured credential locker.

- Use **Variable** to select a preconfigured credential variable.
 - Use **Insecure string** to enter your credential in the field without encryption.
- c) Enter the credential required to access the environment for the **Client ID**.
- d) Select how you would like your secret passed.
- Use **Credential** to pick a preconfigured credential locker.
 - Use **Variable** to select an established variable.
 - Use **Insecure string** to enter your secret in the field without encryption.
- e) Enter the secret code for the OAuth client used in credential grants for the **Client secret**.
6. To configure a **Control room OAuth connection** in Genesys, complete the following steps:
- a) Complete step 1 to step 5 in [Create OAuth connection](#) on page 1827.
- b) Log in to your Genesys environment as an Admin.
- c) Navigate to **Admin > Integrations > OAuth**.
- d) Click **Add client**.
- e) Enter the following information:
- Name of the app.
 - Token duration (default will be 86400).
 - Select **Grant Types** as **Code Authorization**.
 - Add the Callback URL from [Create OAuth connection](#) on page 1827 as an authorized redirect URI.
-
- Note:** For the OAuth connection to be successful you must provide the callback URL.
-
- Click **Save**.
 - Copy the Client ID and Client Secret to use during authentication.
- f) Go to [Create OAuth connection](#) on page 1827 and complete the remaining steps to create an OAuth connection with the above details.
7. To connect using **Control room OAuth connection**, pick a custom connection you have created and stored in the Control Room. For more details, see [Integrate OAuth with Control Room](#) on page 1824.
8. Enter the **Session name** for your changes to the repository.

Conversation action in Genesys

Use the Get conversation action to call details on a conversation from Genesys.

Settings

- Enter the **Conversation ID** of the conversation in Genesys that you want to call details for.
- Enter the **Session name**.
- Select how the outcome data will be saved.

- If using **Multiple variables**, use the following steps for each variable:
 - Click **Add variable mapping**.
 - Enter the **Key** of the variable.
 - **Choose a variable** where the data will be saved.
 - Click **Add** for this division to be saved to the configured variable.
- If using a **Dictionary** variable, then select the established variable.

Division palette

The Genesys package offers a palette of actions to detail and access the role of divisions.

Division palette for Genesys

A division is a way to group and segregate objects while keeping them inside the same organization. For example, you can organize divisions by business unit, country, and office location and then assign respective objects that are configured for each individual division. After you organize and configure divisions, you can use roles to grant user access to division configurations and thus the objects within the respective division.

The Genesys package includes the following division actions:

Action	Description
Add role into division	Detail a role for a division. Add role into division action on page 2559
Bulk-add roles into division	Detail multiple roles in a division. Bulk-add roles into division action on page 2559
Bulk-remove roles for division	Delete multiple roles from a division. Bulk-remove roles for division action on page 2559
Bulk-replace roles in division	Replace multiple roles in a division. Bulk-replace roles in division action on page 2560
Get the home division	Retrieve the home division for the organization. Get the home division action on page 2560
List/search divisions	Retrieve the home division for the organization. List/search divisions action on page 2560
Remove role from division	Delete a grant of a role in a division. Remove role from division action on page 2561

Add role into division action

Settings

Detail a role for a division.

- Enter the ID of the user account for **Internal user ID**.
- Enter the ID of the division for **Division ID**.
- Enter the role of the division for **Role ID**.
- Enter the **Session name** for your changes to the repository.

Bulk-add roles into division action

Settings

Detail multiple roles in a division.

- Select how data is organized within your **Division dataset**.
 - If using a **Table**:
 - Click **Edit table** to create your table.
 - Enter the data into the cells of your table.
 - If using **Variable**, then select the established variable of the data to be added to the division.
- Select the proper ID of the first, second, and third columns. These must correspond with the User, Role, and Division IDs of your dataset.
- Enter the **Session name** for your changes to the repository.
- Optionally, **Choose a variable** where the data will be saved.

Bulk-remove roles for division action

Settings

Delete multiple roles from a division.

- Select how data is organized within your **Division dataset**.
 - If using a **Table**:
 - Click **Edit table** to create your table.
 - Enter the data into the cells of your table.
 - If using **Variable**, then select the established variable of the data to be removed from the division.
- Select the proper ID of the first, second, and third columns. These must correspond with the User, Role, and Division IDs of your dataset.
- Enter the **Session name** for your changes to the repository.

- Optionally, **Choose a variable** where the data will be saved.

Bulk-replace roles in division action

Settings

Replace multiple roles in a division.

- Select how data is organized within your **Division dataset**.
 - If using a **Table**:
 - Click **Edit table** to create your table.
 - Enter the data into the cells of your table.
 - If using **Variable**, then select the established variable of the data to replace in the division.
- Select the proper ID of the first, second, and third columns to map the corresponding User, Role, and Division IDs of your dataset.
- Enter the **Session name** for your changes to the repository.
- Optionally, **Choose a variable** where the data will be saved.

Get the home division action

Settings

Retrieve the home division for the organization.

- Enter the **Session name** for your changes to the repository.
- Select how the outcome data will be saved.
 - If using **Multiple variables**, use the following steps for each variable:
 - Click **Add variable mapping**.
 - Enter the **Key** of the variable.
 - **Choose a variable** where the data will be saved.
 - Click **Add** for this division to be saved to the configured variable.
 - If using a **Dictionary** variable, then select the established variable.

List/search divisions action

Retrieve a list of all divisions defined for the organization.

Settings

- Optionally, enter the **Division name**.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the data will be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on \$SPDI_url\$
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

A yellow arrow points from the "Get Multiple Records" step to a "View variable" dialog box. The dialog box shows the following details for the variable:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

Remove role from division action

Settings

Delete a grant of a role in a division.

- Enter the ID of the user account for **Internal user ID**.
- Enter the ID of the division for **Division ID**.
- Enter the role of the division for **Role ID**.
- Enter the **Session name** for your changes to the repository.

External contact palette

The Genesys package offers a palette of actions to detail and access data for external contact records.

External Contact palette for Genesys

An external contact includes a comprehensive repository of data relevant to making contact with an individual or external organization. From an external contact record, you have a streamlined view of all contact and organization data.

Detail as much or as little relevant data beyond the first and last name of the contact. Optional data can include salutation, title, external organization ID, multiple phones, addresses, and an external system URL.

Note: When providing the organization ID that represents an external organization in Genesys, the contact will be linked to that org.

The Genesys package includes the following external contact actions:

Action	Description
Create contact	Add details of a new contact. Create contact action on page 2562
Delete contact	Delete an external contact. Delete contact action in Genesys on page 2562
List/search contacts	Find and view specific contacts that match your search query. List/search contacts action on page 2562
Update contact	Update the details for an external contact. Update contact action on page 2563

Create contact action

Add details of a new contact.

Settings

- Enter the first name.
- Enter the last name.
- Enter optional data.
- Select **Yes** or **No** for the **Survey opt out**.
- Enter the **Session name** for your changes to the repository.
- Optionally, **Choose a variable** where the external contact ID will be saved.

Delete contact action in Genesys

Delete an external contact.

Settings

- Enter the **External contact ID**.
- Enter the **Session name** for your changes to the repository.

List/search contacts action

Find and view specific contacts that match your search query.

Settings

- Optionally, enter the **External contact ID**.
- Optionally, enter keywords for your **Search query**.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data will be saved.
- **Note:** The output is retrieved as a list of type `dict`. To read an individual record (row) in this list, you need to loop through all the dictionary items using the `read` action and read

or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

time.

Update contact action

Update the details for an external contact.

Settings

- Enter the **External contact ID** of the record that you want to update.
- Enter the first name
- Enter the last name
- Enter optional data.
- Select **Yes** or **No** for **Survey opt out**.
- Enter the **Session name** for your changes to the repository.

Group palette

The Genesys package offers a palette of actions to detail and access data for grouping records.

Group palette for Genesys

Groups organize people with similar traits. For example, users that share skills, locations, or other information maintained in Genesys Cloud can be grouped for organizational functions.

Groups can be work-related or social to assist in project and priorities. Examples of groups include the following:

- Subject Matter Experts (SMEs): A group of SMEs can let others in the organization know the most current information.
- Projects: Groups related to projects streamline information to the team and expedite updates and planning.
- Locations: Groups can simplify communication for geographical updates and events.

The Genesys package includes the following group actions:

Action	Description
Bulk-add members into group	Add multiple members into a group. Bulk-add members into group action on page 2564
Delete member	Delete a member from a group. Delete member action in Genesys on page 2564
List groups	View all groups. List groups action on page 2564
List members	List all the members in a specific group. List members (Group) action on page 2565

Bulk-add members into group action

Add multiple members into a group.

Settings

- Enter the **Group ID**.
- Select how the data will be entered to begin adding user data.
 - If using a **List**:
 - Select the data **Type**.
 - Enter the **Value** of the data in the list.
 - If using **Variable**, then select the established variable of the data to be entered in the group.
- Enter the **Session name** for your changes to the repository.

Delete member action in Genesys

Delete a member from a group.

Settings

- Enter the **Group ID**.
- Select how the data will be entered to begin deleting user data from the group.
 - If using a **List**:
 - Select the data **Type**.
 - Enter the **Value** of the data in the list.
 - If using **Variable**, then select the established variable of the data to be deleted from the group.
- Enter the **Session name** for your changes to the repository.

List groups action

View all groups.

Settings

- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data will be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on \$PDI_url\$
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

A yellow arrow points from the 'Get Multiple Records' step to the 'View variable' dialog box. The dialog box shows the following details:

Type	Subtype
List	* Any
Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

List members (Group) action

List all the members in a specific group.

Settings

- Enter the **Group ID**.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data will be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

time.

Language palette

The Genesys package offers a palette of actions to detail languages for call-routing purposes.

Language palette for Genesys

Languages are separate from Automatic Call Distribution (ACD) skills. For example, Genesys Cloud will prioritize an agent that speaks the language requested by the customer over an agent who is more skilled but cannot speak the requested language. An agent that cannot speak the language of the customer does not receive that interaction regardless of ACD skill.

Attributing users with languages empowers your team to handle diverse calls with effective communication. The Genesys package includes the following language actions:

Action	Description
Add routing language	Add a routing language to a user. Add routing language action on page 2567
Bulk-add routing languages to user	Attribute multiple users with languages. Bulk-add routing languages to user action on page 2567
List user's routing languages	List the languages attributed to a user. List user's routing languages action on page 2567
List all routing languages	List all the supported languages. List all routing languages action on page 2568
Remove routing language from user	Remove an attributed language from a user. Remove routing language from user action on page 2569

Add routing language action

Add a routing language to a user.

Settings

- Enter a unique user ID for the **Internal user ID**.
- Enter the **Language ID** that is to be added to the user.
- Enter the user's language **Proficiency** with a value of 0-5. Zero is low proficiency.
- Enter the **Session name** for your changes to the repository.

Bulk-add routing languages to user action

Attribute multiple users with languages.

Settings

- Select how the dataset will be entered.
 - If using a **Table**:
 - Click **Edit table** to create your table.
 - Enter the data of the cells for your table.
 - If using **Variable**, then select the established variable of the data to be added to the user.
- Select the proper ID of the first, second, and third columns to map the corresponding User, Role, and Division IDs of your dataset.
- Enter the **Session name** for your changes to the repository.
- Optionally, **Choose a variable** where the outcome data will be saved.

List user's routing languages action

List the languages attributed to a user.

Settings

- Enter the unique user ID for the **Internal user ID**.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data will be saved.

Note: The output is retrieved as a list of type `dict`. To read an individual record (row) in this list, you need to loop through all the dictionary items using the `get` action and read or extract the records (rows) individually. For example, the output of `get multiple records` is saved in the variable `list_of_records_any`. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on \$PDI_url\$
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

A yellow arrow points from the 'Loop' action to a 'View variable' dialog box. The dialog box shows the following details:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items

Additional properties shown in the dialog:

- Use as input: No
- Use as output: No
- Constant (read-only): No
- Default value (optional): This list is empty

time.

List all routing languages action

List all the supported languages.

Settings

- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data will be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on \$PDI_url\$
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

A yellow arrow points from the 'Loop' action to a 'View variable' dialog box. The dialog box shows the following details:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items

Additional properties shown in the dialog:

- Use as input: No
- Use as output: No
- Constant (read-only): No
- Default value (optional): This list is empty

time.

Remove routing language from user action

Remove an attributed language from a user.

Settings

- Enter the unique user ID for the **Internal user ID**.
- Enter the **Language ID** to be removed.
- Enter the **Session name** for your changes to the repository.

External organization palette

The Genesys package offers a palette of actions to detail and access data for external organization records.

External organization palette for Genesys

External organizations are your customers, partners, and other businesses that you interact with. An organization (org) can also be considered an account and is related to External Contacts in that contacts belong to an org. Simply put, contacts are customers and the relationship defines what business a contact might be calling about. Allowing an agent to view customer information and the org of the customer help the agent to quickly understand the relevant business details to best serve their needs. Therefore, having the org details available to bots can enable workflows, such as automatically importing account data into Genesys from other systems, using Genesys Org details to look up open cases for the account from an external case management tool, and so on.

Similar to contacts, you can detail as much or as little relevant data beyond the name of the org. Optional data can include company type, industry, multiple phones, addresses, tags, and websites. The Genesys package includes the following external organization actions:

Action	Description
Create organization	Create the initial external organization record. Create organization action on page 2570
Delete organization	Delete a record of an external organization. Delete organization action on page 2570
Get organization	Call the details of an external organization record. Get organization action on page 2570
List/search organizations	Call a list of external organizations that match your search query. List/search organizations action on page 2570
Update organization	Update an external organization record with new or additional data. Update organization action on page 2571

Create organization action

Create the initial external organization record.

Settings

- Enter the **Name** of the org.
- Enter the optional data.
- Select whether the org approved to be contacted through **Phone SMS**.
- Select whether the org approved to be contacted through **Fax SMS**.
- Enter the **Session name** for your changes to the repository.
- Optionally, **Choose a variable** where the org ID can be saved.

Delete organization action

Delete a record of an external organization.

Settings

- Enter the **ID** for the external organization.
- Enter the **Session name** for your changes to the repository.

Get organization action

Call the details of an external organization record.

Settings

- Enter the **ID** for the external organization.
- Enter the **Session name** for your changes to the repository.
- Select how the outcome data will be saved.
 - If using **Multiple variables**, use the following steps for each variable:
 - Click **Add variable mapping**.
 - Enter the **Key** of the variable.
 - **Choose a variable** where the data will be saved.
 - Click **Add** for this data to be saved to the configured variable.
 - If using a **Dictionary** variable, then select the established variable where the outcome data can be saved.

List/search organizations action

Call a list of external organizations that match your search query.

Settings

- Optionally, enter keywords for your **Search query**.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data will be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on \$PDI_urls
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

A yellow arrow points from the "Get Multiple Records" step to a "View variable" dialog box. The dialog box shows the following details:

Type	Subtype
List	* Any
Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

Update organization action

Update an external organization record with new or additional data.

Settings

- Enter the **ID** of the external organization record.
- Enter the **Name** of the org.
- Enter the optional data.
- Select whether the org approved contact through **Phone SMS**.
- Select whether the org approved contact through **Fax SMS**.
- Enter the **Session name** for your changes to the repository.

Phone palette

The Genesys package offers a palette of actions to detail and access data for phone records.

Phone palette for Genesys

Genesys Cloud supports the WebRTC technology with the Genesys Cloud WebRTC phone. The Genesys Cloud WebRTC phone runs from a browser, that is, there are no special hardware

requirements or software to download. When the Genesys Cloud WebRTC phone is enabled, you can immediately use it to make and receive calls. It is an important part of the onboarding process that phones be created and assigned to agents so that calls are effectively routed from the queue to agents.

Configuring a Genesys Cloud WebRTC phone is a two-step operation. First, base settings must be created and configured by the admin and must already be established. Second, the phone is created and configured to retrieve established base settings. These secondary tasks can be automated. The Genesys package includes the following phone actions:

Action	Description
Assign phone	Assign a phone line to a user. Assign phone action on page 2572
Create a phone	Create a phone record. Create a phone action on page 2572
List phone base settings	Get a list of phone base settings. List phone base settings action on page 2573
List/search phones	Get a list of phones. List/search phones action on page 2573
List/search sites	Get a list of sites. List/search sites action on page 2574
Remove a phone	Remove a phone record. Remove a phone action on page 2575

Assign phone action

Assign a phone line to a user.

Settings

- Enter a unique user ID for the **Internal user ID**.
- Enter a line ID to assign the **Phone's line ID** to the user.
- Enter the **Session name** for your changes to the repository.

Create a phone action

Create a phone record.

Settings

- Enter a **Name** for the phone.
- Enter the **Phone base setting ID** to route the preconfigured base settings.
- Enter the **Site ID** where the phone is located.
- Enter the **Web rtc user ID** of the WebRTC user.
- Enter the **Session name** for your changes to the repository.
- Optionally, **Choose a variable** for the Phone ID.
- Optionally, **Choose a variable** for the Phone's line ID.

List phone base settings action

Get a list of phone base settings.

Settings

- Optionally, enter a **Name** for the list.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data can be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on SPDI_urls
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

An orange arrow points from the "Get Multiple Records" step to the "View variable" dialog box. The dialog box shows the following details:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

List/search phones action

Get a list of phones.

Settings

- Optionally, enter a **Name** for the list.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data can be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

time.

List/search sites action

Get a list of sites.

Settings

- Optionally, enter a **Name** for the list.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data can be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

time.

Remove a phone action

Remove a phone record.

Settings

- Enter the **Phone ID** to be removed.
- Enter the **Session name** for your changes to the repository.

Queues palette

The Genesys command package offers a palette of actions to detail and access data for grouping records.

Queues palette for Genesys

Queues are the waiting lines of interactions. Agents select the **On Queue** status to enter their predefined queues. Contact center queue settings include creating and managing queues for voice and chat channels for the entire organization. The Genesys package includes the following queues actions:

Action	Description
Add to queue	Add selection to queue. Add to queue action in Genesys on page 2575
List members	List the members of a queue. List members (Queues) action on page 2576
List/search queues	Retrieve a list of queues that match your input criteria. List/search queues action on page 2576
Remove from queue	Remove selected users from a queue. Remove from queue action on page 2577

Add to queue action in Genesys

Add selection to queue.

Settings

- Enter the **Session name** for your changes to the repository.
- Enter the **Queue ID** of the queue that you want to add.
- Select how the data will be entered to begin adding user data to the queue.
 - If using a **List**:
 - Select the data **Type**.
 - Enter the **Value** of the data in the list.

- If using **Variable**, then select the established variable of the data to be entered in the queue.

List members (Queues) action

List the members of a queue.

Settings

- Enter the **Session name** for your changes to the repository.
- Enter the **Queue ID** of the queue that you want to add.
- **Choose a variable** where the outcome data can be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on \$PDI_url\$
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

An orange arrow points from the "Get Multiple Records" step to a "View variable" dialog box. The dialog box shows the following details:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

List/search queues action

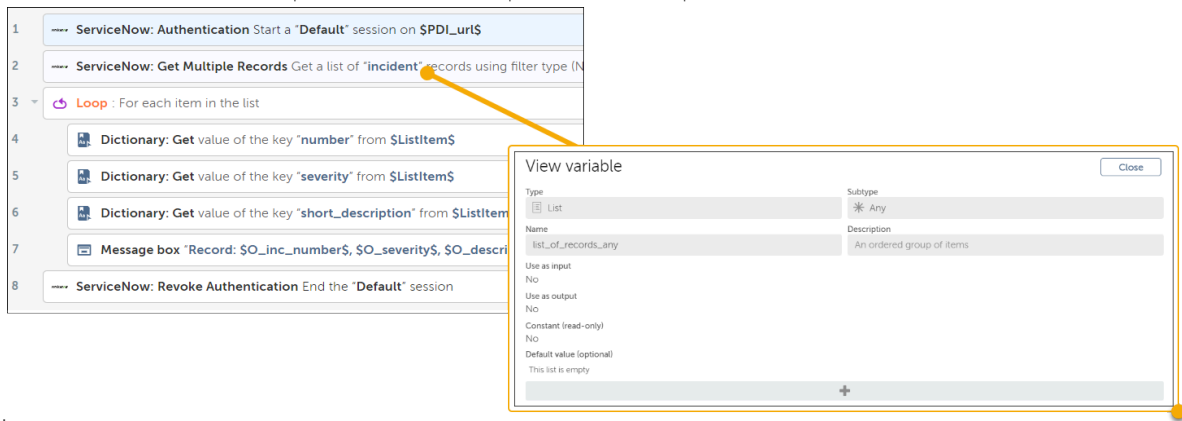

Retrieve a list of queues that match your input criteria.

Settings

- Optionally, enter a **Name** for the list.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data can be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

time.

Remove from queue action

Remove selected users from a queue.

Settings

- Enter the **Session name** for your changes to the repository.
- Enter the **Queue ID** for the queue that you want to remove users from.
- Select how the data will be entered to begin adding user data to the queue.
 - If using a **List**:
 - Select the data **Type**.
 - Enter the **Value** of the data in the list.
 - If using **Variable**, then select the established variable of the data to be entered in the queue.

Role palette

The Genesys package offers a palette of actions to detail and access data for the roles of users.

Role palette for Genesys

Because permissions are based on the assigned role, the role of users is important in the onboarding process. Tasks are then assigned based on the permissions that a user has. The Genesys package includes the following role actions:

Action	Description
Add users to role	Add a list of users to a role. Add users to role action on page 2578
List/search roles	Retrieve a list of roles for the organization. List/search roles action on page 2578

Action	Description
List user's roles	Retrieve a list of roles and permissions for a user. List user's roles action on page 2579
List users in a role	Retrieve a list of the unique user IDs of the users in the specified role. List users in a role action on page 2580
Remove users from role	Remove a list of users from a specific role. Remove users from role action on page 2581
Set the user's roles	Set the roles for a specific user. Set the user's roles action in Genesys on page 2581

Add users to role action

Add a list of users to a role.

Settings

- Enter the **Role ID** of the role that you want to add users to.
- Select how the data will be entered to begin adding user data to the role.
 - If using a **List**:
 - Select the data **Type**.
 - Enter the **Value** of the data in the list.
 - If using **Variable**, then select the established variable of the data to be added to the role.
- Enter the **Session name** for your changes to the repository.

List/search roles action

Retrieve a list of roles for the organization.

Settings

- Optionally, enter the **Role name** for the list.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data can be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on \$PDI_url\$
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N)
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

A yellow arrow points from the "Loop" action to a "View variable" dialog box. The dialog box shows the following details:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

List user's roles action

Retrieve a list of roles and permissions for a user.

Settings

- Enter the unique ID of the user for the **Internal user ID**.
- Enter the **Session name** for your changes to the repository.
- Select how the outcome data will be saved.
 - If using **Multiple variables**, use the following steps for each variable:
 - Click **Add variable mapping**.
 - Enter the **Key** of the variable.
 - **Choose a variable** where the data will be saved.
 - Click **Add** for this list to be saved to the configured variable.
 - If using a **Dictionary** variable, then select the established variable where the outcome data can be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on \$SPDI_url\$
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

The 'View variable' dialog box displays the following information:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items

Additional details in the dialog:

- Use as input: No
- Use as output: No
- Constant (read-only): No
- Default value (optional): This list is empty

time.

List users in a role action

Retrieve a list of the unique user IDs of the users in the specified role.

Settings

Retrieve a list of the unique user IDs of the users in the specified role.

- Enter the **Role ID** for the list.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data can be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. - Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

The 'View variable' dialog box displays the following information:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items

Additional details in the dialog:

- Use as input: No
- Use as output: No
- Constant (read-only): No
- Default value (optional): This list is empty

time.

Remove users from role action

Remove a list of users from a specific role.

Settings

- Enter the **Role ID** that you want to remove users from.
- Select how the data will be entered to begin adding user data that will be removed from the role.
 - If using a **List**:
 - Select the data **Type**.
 - Enter the **Value** of the data in the list.
 - If using **Variable**, then select the established variable of the data to be removed from the role.
- Enter the **Session name** for your changes to the repository.

Set the user's roles action in Genesys

Set the roles for a specific user.

Settings

- Enter the unique ID of the user for the **Internal user ID**.
- Select how the data will be entered to begin adding role data that will be attributed to the user.
 - If using a **List**:
 - Select the data **Type**.
 - Enter the **Value** of the data in the list.
 - If using **Variable**, then select the established variable of the data to be attributed to the user.
- Enter the **Session name** for your changes to the repository.

Skill palette

The Genesys package offers a palette of actions to detail and access the skills of agents.

Skill palette for Genesys

Genesys allows for defining Automatic Call Distribution (ACD) and profile-based skills for agents. An ACD skill routes each contact to the available agents who can best meet the contact's needs. Profile skill data becomes keywords for advanced searches and parameters for creating groups and can also be used by the Workforce Management capabilities to create schedule scenarios. The Genesys package includes the following skill actions:

Action	Description
Add user routing skills	Attribute routing skills to a user. Add user routing skills action on page 2582
Bulk-add routing skills	Add multiple routing skills to a single user. Bulk-add routing skills action on page 2582
Bulk-replace routing skills	Replace multiple routing skills for a single user. Bulk-replace routing skills action on page 2583
List/search routing skills	Retrieve a list of routing skills. List/search routing skills action on page 2583
List user's routing skills	Retrieve a list of user's routing skills. List user's routing skills action on page 2584
Remove user routing skills	Remove routing skills for a user. Remove user routing skills action on page 2584

Add user routing skills action

Attribute routing skills to a user.

Settings

- Enter a unique user ID for the **Internal user ID**.
- Enter the **Skill ID** that is to be added to the user.
- Enter the user's skill **Proficiency** with a value of 0-5. Zero is low proficiency.
- Enter the **Session name** for your changes to the repository.

Bulk-add routing skills action

Add multiple routing skills to a single user.

Settings

- Select how the skill dataset will be entered.
 - If using a **Table**:
 - Click **Edit table** to create your table.
 - Enter the data in the cells for your table.
 - If using **Variable**, then select the established variable of the data to be added to the user.
- Select the proper data of the first, second, and third columns to map the corresponding **User ID**, **Skill ID**, and **Skill proficiency** of your dataset.
- Enter the **Session name** for your changes to the repository.
- Optionally, **Choose a variable** where the outcome data will be saved.

Bulk-replace routing skills action

Replace multiple routing skills for a single user.

Settings

- Select how the skill dataset will be entered.
 - If using a **Table**:
 - Click **Edit table** to create your table.
 - Enter the data in the cells for your table.
 - If using **Variable**, then select the established variable of the data to be replaced.
- Select the proper data of the first, second, and third columns to map the corresponding **User ID**, **Skill ID**, and **Skill proficiency** of your dataset.
- Enter the **Session name** for your changes to the repository.
- Optionally, **Choose a variable** where the outcome data will be saved.

List/search routing skills action

Retrieve a list of routing skills.

Settings

- Optionally, enter a **Skill name** for the list.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data will be saved.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

An orange arrow points from the "Get Multiple Records" step to a "View variable" dialog box. The dialog box shows the following details:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

Remove user routing skills action

Remove routing skills for a user.

Settings

- Enter a unique user ID for the **Internal user ID**.
- Enter the **Skill ID** that you want to remove.
- Enter the **Session name** for your changes to the repository.

User palette

The Genesys package offers a palette of actions to detail and access user records.

User palette for Genesys

A person is on-boarded as a user. User records can then be assigned with different attributes and roles. The user record begins the process of building out a fully organized work force. The Genesys package includes the following user actions:

Action	Description
Create user	Create a new user. Create user action in Genesys on page 2585
Delete user	Delete an existing user. Delete user action in Genesys on page 2585
Get user	Retrieve the details of a user. Get user action in Genesys on page 2586
List/search users	Retrieve a list of users that match your input criteria. List/search users action on page 2586
Update user	Update the details of a user. Leave any field blank if no update is needed. Update user action in Genesys on page 2587

Create user action in Genesys

Create a new user.

Settings

- Enter the user's **Email (login ID)**.
- Select how you would like your password entered.
 - Use **Credential** to pick a preconfigured credential locker.
 - Use **Variable** to select an established credential variable.
 - Use **Insecure string** to enter your credential in the field.
- Enter the **Password** required for the user to sign in.
- Enter the **Full name** of the user.
- Enter a **Division ID** for the user.
- Select whether the user **State** is active or inactive in the repository.
- Optionally, enter the user's **Title** and **Department**.
- Enter the **Session name** for your changes to the repository.

Delete user action in Genesys

Delete an existing user.

Settings

- Enter the unique user ID for the **Internal user ID** that you want to delete.
- Enter the **Session name** for your changes to the repository.

Get user action in Genesys

Retrieve the details of a user.

Settings

- Enter a unique user ID for **Internal user ID**.
- Enter the **Session name** for your changes to the repository.
- Select how the outcome data will be saved.
 - If using **Multiple variables**, use the following steps for each variable:
 - Click **Add variable mapping**.
 - Enter the **Key** of the variable.
 - **Choose a variable** where the data will be saved.
 - Click **Add** for this data to be saved to the configured variable.
 - If using a **Dictionary** variable, then select the established variable where outcome data can be saved.

List/search users action

Retrieve a list of users that match your input criteria.

Settings

- Select how the data will be entered to begin adding user data to the search.
 - If using a **List**:
 - Select the data **Type**.
 - Enter the **Value** of the data in the list.
 - If using **Variable**, then select the established variable of the data to be added to the list.
- Optionally, select whether the **State** of the user is active or inactive.
- Enter the **Session name** for your changes to the repository.
- **Choose a variable** where the outcome data can be saved.

Note: The output is retrieved as a list of type `dict`. To read an individual record (row) in this list, you need to loop through all the dictionary items using the `loop` action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable `list_of_records_any`. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

The screenshot shows a workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on \$PDI_url\$
- ServiceNow: Get Multiple Records Get a list of "incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

The 'View variable' dialog box shows the following details:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

Update user action in Genesys

Update the details of a user. Leave any field blank if no update is needed.

Settings

- Enter a unique user ID for the **Internal user ID**.
- Enter the data that you want to update, such as the following:
 - **Email (login ID)**
 - **Department**
 - **Manager**
 - **Date hired**
 - **Employee type**
 - **Biography, Interests, or Hobbies**
 - **Spouse**
- Select to turn **Auto answer** on or off for connecting calls to the user.
- Enter the **Session name** for your changes to the repository.

Google Calendar package

The **Google Calendar** package contains actions that enable you to automate creating and deleting events.

Before you start

Use the actions in the Google Calendar package in the following order:

1. Use the **Connect** to establish a connection to the Google server.
See [Using the Connect action for Google packages](#) on page 2589.
2. Use a combination of available in this to automate tasks.

Note: To use from other Google , establish a connection using the **Connect** from that .

3. Use the **Disconnect** to terminate the connection.

Actions in the Google Calendar package

The **Google Calendar** package includes the following actions:

Action	Description
Create event	See Using the Create event action in Google Calendar on page 2588.
Connect	See Using the Connect action for Google packages on page 2589.
Disconnect	See Disconnect action for Google packages on page 2591.
Delete event	See Delete event action in Google Calendar on page 2591.

Related reference

[Google Calendar package updates](#) on page 851

Review the updates in released versions of the Google Calendar package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using the Create event action in Google Calendar

Use the **Create event** action to create an event and specify event attendees, duration, location, recurrence, and title. During run time, this action triggers an email notification to meeting attendees.

To create a new calendar event, do the following:

1. Enter the session name you used to connect to the G-Suite server in the **Connect** action.
See [Using the Connect action for Google packages](#) on page 2589.
2. Enter the event title.
3. Optional: Enter the location.
4. Optional: Enter the attendees' email addresses, separated with commas.
5. Enter the start date.
Use the format yyyy-MM-dd.
6. Enter the end date.
Use the format yyyy-MM-dd.
7. Select the **All Day** or **Specify Time** option from the **Event Time** option.
 - If you select the **All Day** option, you do not need to provide any additional details.
 - If you select the **Specify Time** option, complete the following fields:
 - Specify the **Start Time** using the HH:mm:ss format.

- Specify the **End Time** using the HH:mm:ss format.
8. Select the **Use System Timezone** or **Specify Timezone** option from the **Timezone** option.
 - If you select the **Use System Timezone** option, you do not need to provide any additional details.
 - If you select the **Specify Timezone** option, complete the following fields:
 - Specify the **Start Timezone**.
 - Specify the **End Timezone**.
 9. Optional: Mark the **Recurring** option to make this event repeat.
 10. Select a Visibility option from the drop-down list.
Select from **Default**, **Public**, or **Private**.
 11. Optional: Enter an event description.
 12. Optional: Select a string variable from the drop-down list to store the id of the created event.
 13. Click **Save**.

Using the Connect action for Google packages

Use the **Connect** action to establish a connection with the Google server in order to use other actions from that same package to automate tasks. All of the fields in this action accept a credential from the Credential Vault, variable, or a user-input value.

Configure the OAuth settings in the Google Cloud Platform and retrieve the credentials necessary to connect Automation Anywhere Enterprise with your Google G Suite applications.

1. If you have not already done so, [create a project](#).
2. [Enable the APIs](#) for the Google G Suite applications you want to automate, such as the Google Drive API, Google Calendar API, and Google Sheets API.
3. Do the steps in [Setting up OAuth 2.0](#) to generate the Client ID and Secret.

Note:

- Select the **Web application** option.
- Add this authorized redirect URI: `http://localhost:8888/Callback`

-
4. Do these steps to set up [user consent](#) for the username that you will use to connect to the Automation Anywhere Enterprise.
 1. In the **Actions** palette, double-click or drag the **Connect** action from the package you want to use.
 2. In the **Username** field, you can provide a valid username or select the credential or credential variable that contains your Google username. To enter a value, click **Insecure string**.
 3. If you are configuring the **Connect** action for the Google Calendar or Google Sheets package, enter a session name.
 4. In the **Client Id** field, select the credential or credential variable that contains the client ID. To enter a value, click **Insecure string**.
 5. In the **Redirect URI** field, enter `http://localhost:8888/Callback`

Note: For the Google Sheets package, the **Redirect URI** attribute is not supported. Enter the fixed redirect URL directly in Google Cloud Platform: `http://localhost:8888/Callback`

6. In the **Client secret** field, select the credential or credential variable that contains the access token. To enter a value, click **Insecure string**.
 7. For Google Sheets, you can specify the wait time (in minutes) in the **Wait for action to complete (In minutes)** field when performing actions such as **Get**, **Set**, or **Delete**. By default, the wait time is 10 minutes.
If the Google sheet does not open within the time you specify, the task proceeds to execute the next set of actions.
-

Note: When you use **Connect** action to connect to the Google server, the option **Wait for action to complete (In minutes)** is only supported in Google Sheets package.

8. Click **Save**.
9. After you add actions from a specific Google package, use the **Disconnect** action from that same Google package to terminate the connection.

The first time the bot runs, the Google login window is displayed. You must select the Google account and approve the requested access permissions.

The token file gets generated for the first time after you provide the access permissions when the bot gets deployed. It is created based on values that you provide in the **Username**, **Client Id** and **Client secret** field, and asks for credentials only the first time to provide the access permission. Next time it uses the same token file to connect to the Google Sheets.

The token file is located at `C:\Users\<username>\AppData\Local\AutomationAnywhere\G-SuitAuth`, where `C:\Users\<username>` is the user home directory of the respective system.

If you enter the correct credentials when providing access permissions for the first time and can connect to the Google Sheets successfully, then next time if there is a change in only the password, you need not delete the token file as it will work as expected.

Use other the actions from the same Google package to automate tasks. To use actions from another Google packages, establish a connection using the **Connect** action from that package.

Related reference

[Google Calendar package](#) on page 2587

The **Google Calendar** package contains actions that enable you to automate creating and deleting events.

[Google Drive package](#) on page 2591

Automate tasks related to files and folders by using the actions in the **Google Drive** package.

[Google Sheets package](#) on page 2603

The **Google Sheets** package contains actions that enable you to automate tasks involving cells, columns, rows, and sheets.

Disconnect action for Google packages

Use the **Disconnect** action from a specific Google package to terminate the connection after you have added actions from the same Google package.

Settings

- In the **Username** field, you can provide a valid username or select the credential or credential variable that contains your Google username. To enter a value, click **Insecure string**.
- For Google Calendar and Google Sheets packages, enter the session name that you used in the **Connect** action.
- Select the check box **Logout from the browser** if you want to sign off from your account.

Delete event action in Google Calendar

You can remove an event from the calendar using the **Delete event** action.

Settings

Removes the event from the calendar.

- Enter the same session name that you provided in the **Connect** .
- Enter the **Event Id**. This is the string in the URL that appears after `/eventedit/` when you open an event for editing.
- Optional: Assign the event to a String variable.

Google Drive package

Automate tasks related to files and folders by using the actions in the **Google Drive** package.

Before you start

Use the actions in the Google Drive package in the following order:

1. Use the **Connect** to establish a connection to the Google server.
See [Using the Connect action for Google packages](#) on page 2589.
2. Use a combination of available in this to automate tasks.

Note: To use from other Google , establish a connection using the **Connect** from that .

3. Use the **Disconnect** to terminate the connection.
See [Disconnect action for Google packages](#) on page 2591.

Actions in the Google Drive package

The **Google Drive** package includes the following actions:

Action	Description
Check permissions	See Check permissions action in Google Drive on page 2594.
Copy file	See Copy file action in Google Drive on page 2595.
Copy folder	See Copy folder action in Google Drive on page 2595.

[Google Drive package updates](#) on page 853

Review the updates in released versions of the Google Drive package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Check permissions action in Google Drive

The **Check permissions** action enables you to check permissions for a file or folder on Google Drive and returns `read`, `write`, or `delete` to a list variable.

Settings

Checks for a file or folder permissions and returns `read`, `write`, or `delete` to a list variable.

- Enter the same username that you provided in the **Connect**.
- Select whether to check permissions for a file or a folder. Select **File** or **Folder** and enter the name and path to the file or folder. To check the permissions of files shared with you in Google Drive, select **File ID** to enter the file id. You can extract the file id from the URL of the file name and enter it in the **File ID** field.

Note: If you select the **File ID** option, the user with a **Commenter** role with the write access will observe that the bot does not check the write permission and returns the value as false.

- To check the various kinds of permissions, select **Read**, **Write**, or **Delete**. This returns `read`, `write`, or `delete` to a Boolean variable.
- Select or create a Boolean variable to hold the permissions.

Copy file action in Google Drive

The Copy file action enables you to copy a file from one folder to another on Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the source file by file path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is <https://docs.google.com/spreadsheets/d/12dlAwvrEA4JeLysfFky9>, the ID is 12dlAwvrEA4JeLysfFky9.

- Select whether to identify the destination folder by directory path and name, or by ID.
- Optional: Mark the **Rename file** option and enter the new file name.

Copy folder action in Google Drive

Use Copy folder action to copy a folder from one location to another.

Settings

Copies a folder from one location to another.

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the source file by folder path and name, or by ID. If this is a shared folder, you must use the **Folder ID** option.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is <https://docs.google.com/spreadsheets/d/12dlAwvrEA4JeLysfFky9>, the ID is 12dlAwvrEA4JeLysfFky9.

- Select whether to identify the destination folder by directory path and name, or by ID.

Create file permission action in Google Drive

You can create a new permission for a file by using the Create file permission action.

Settings

Creates a new permission for a file.

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the file by file path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is <https://docs.google.com/spreadsheets/d/12dlAwvrEA4JeLysfFky9>, the ID is 12dlAwvrEA4JeLysfFky9.

- Select a role. For more information, see [Google Drive Roles](#).
- Select the grantee type. Choose from:
 - User
 - Group
 - Domain
 - Anyone
- If you select User or Group, enter the email address. If you select domain, enter the domain.
- Optional: Select or create a variable to hold the permission ID.

Create folder action in Google Drive

This action enables you to create a folder in Google drive.

Settings

Creates a folder.

- Enter the same username that you provided in the **Connect** .
- Enter the parent folder where to create the folder. To create the folder in the root folder enter `root`.
- Enter the folder name.
- Optional: Select or create a string variable to hold the ID of the new folder.

Note: You cannot create a folder in the Shared with me folder because Google API does not support it.

Delete file action in Google Drive

Use the Delete file action to delete a file on your Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the file by file path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12d1AwvrEA4JeLysfFky9`, the ID is `12d1AwvrEA4JeLysfFky9`.

- Optional: Select or create a boolean variable to hold the file delete status.

Delete file permission action in Google Drive

You can delete a file permission for a file by using the Delete file permission action.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the file by file path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is <https://docs.google.com/spreadsheets/d/12d1AwvrEA4JeLysfFky9>, the ID is 12d1AwvrEA4JeLysfFky9.

- In the **Permission id** field, enter the permission ID.
- Optional: Select or create a variable to hold the permission ID.

Delete folder action in Google Drive

Delete folder action enables you to delete a folder from the Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the folder by path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is <https://drive.google.com/drive/folders/0B0MqCb--3Y8QQz1JcVRJb3UxcTg>, the ID is 0B0MqCb--3Y8QQz1JcVRJb3UxcTg.

- Optional: Select or create a boolean variable to hold the folder delete status.

Download file action in Google Drive

You can download a file from your Google Drive to a specific location on your desktop.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the file by file path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is <https://docs.google.com/spreadsheets/d/12d1AwvrEA4JeLysfFky9>, the ID is 12d1AwvrEA4JeLysfFky9.

- Specify the download file path. For example, `C:/Users/Downloads`.
- Optional: Mark the **Overwrite existing file** option to overwrite the file of the same name.
- Optional: Mark the **Rename file** option to enter a new name for the downloaded file.

- Optional: Select or create a variable to hold the ID of the downloaded file.

Find file/folder action in Google Drive

The Find file/folder action enables you to find files or folders in a specific directory in your Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to search for files or folders.
- Enter the source folder to search in. For example, `/Home/Accounts/`.
- Specify whether to return exact matches or
- Enter the file or folder name to search for.
- Select or create a variable to hold the list of files or folders.

Get file information action in Google Drive

Use the **Get file information** action in the Google Drive package to enable you to get the file information of a file from Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the file by file path and name, or by ID. If this is a shared folder, you must use the **FILE ID** option.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12d1AwvrEA4JeLysfFky9`, the ID is `12d1AwvrEA4JeLysfFky9`

- Select or create a dictionary variable to hold the file information which is stored in two keys: the `name` key holds the file name and the `extension` key holds the file extension.

Get file permission action in Google Drive

Use the **Get file permission** action in the Google Drive package to enable you to retrieve file permission of a file or a folder from Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the file by file path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12dlAwvrEA4JeLysfFky9`, the ID is `12dlAwvrEA4JeLysfFky9`.

- Select or create a list variable to hold the file permissions.

Move file action in Google Drive

Use the **Move file** action in the Google Drive package to enable you to move file from one folder to another on Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
 - Select whether to identify the file by file path and name, or by ID.
-

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12dlAwvrEA4JeLysfFky9`, the ID is `12dlAwvrEA4JeLysfFky9`.

- Select whether to identify the destination folder by directory path and name, or by ID.
-

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12dlAwvrEA4JeLysfFky9`, the ID is `12dlAwvrEA4JeLysfFky9`.

Move folder action in Google Drive

Use the **Move folder** action in the Google Drive package to enable you to move a folder from one location to another on Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
 - Select whether to identify the source file by folder path and name, or by ID. If this is a shared folder, you must use the **Folder ID** option.
-

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12dlAwvrEA4JeLysfFky9`, the ID is `12dlAwvrEA4JeLysfFky9`.

- Select whether to identify the destination folder by directory path and name, or by ID.

Rename file action in Google Drive

Use the **Rename file** action in the Google Drive package to enable you to rename a file on Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the file by file path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12d1AwvrEA4JeLysfFky9`, the ID is `12d1AwvrEA4JeLysfFky9`.

- Enter the new file name.

Rename folder action in Google Drive

Use the **Rename folder** action in the Google Drive package to enable you to rename a folder in a specific directory on Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
- Select whether to identify the folder by directory path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12d1AwvrEA4JeLysfFky9`, the ID is `12d1AwvrEA4JeLysfFky9`.

- Enter the new folder name.

Upload file action in Google Drive

Use the **Upload file** action in the Google Drive package to enable you to upload a file from your computer to Google Drive.

Settings

- Enter the same username that you provided in the **Connect** .
- Enter the file path and name.
- Select whether to identify the folder where to upload the file by directory path and name, or by ID.

Note: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12d1AwvrEA4JeLysfFky9`, the ID is `12d1AwvrEA4JeLysfFky9`.

- Optional: Mark the **Overwrite existing file** option to overwrite the file of the same name.
- Optional: Select or create a variable to hold the ID of the uploaded file.

Google Document AI package

Extract data from documents by using the Google Document AI capabilities of the Google Document AI package in your bots.

Before you start

Create a processor in Google Document AI. [Create a processor](#).

Use the actions in the Google Drive package in the following order:

1. Use the **Connect** action to establish a connection with your Google Cloud service account.
2. Configure the **Extract** action to specify the location of the documents to be extracted and provide the processor details.
3. Use the **Disconnect** action to terminate the connection.

Actions in the Google Document AI package

The Google Document AI package includes the following actions:

Action	Description
Connect	<p>Establishes a connection with the Google Cloud service account.</p> <p>Provide the following:</p> <ul style="list-style-type: none"> • Key file path: Select the JSON file that contains your Google Cloud service account key. • Google Cloud service session: Enter a unique name for the session.
Extract	<p>Sends documents to Google Document AI for data extraction.</p> <p>Using the Extract action for Google Document AI on page 2602</p>
Disconnect	<p>Disconnects from the Google service account.</p> <p>In the Session name field, enter the name of the session that you used to connect to the Google service account in the Connect action.</p>

Review the updates in released versions of packagesuch as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using the Extract action for Google Document AI

Configure the **Extract** action to enable your bot to send documents to Google Document AI for data extraction and retrieve the output in JSON format.

Login to your Google Cloud account and go to the Processors page to retrieve your custom endpoint. See [Use your processor endpoint](#).

Your custom endpoint should follow this format: `https://LOCATION-documentai.googleapis.com/API_VERSION/projects/PROJECT_ID/locations/LOCATION/processors/PROCESSOR_ID`. You will need the parameters in bold to configure this action.

1. Double-click or drag the **Google Document AI > Extract** action.
2. In the **Document file path** field, provide the file path to the document you want to process.

Note: If using this action within a **Loop** action to process all the documents in a folder, be sure to include a period between the variable holding the file name and the one holding the extension. For example, `C:\Documents\${dictFile (name)}.${dictFile (extension)}`.

3. Provide the following information, which is found in your custom endpoint.
 - Project id
 - Processor id
 - Location
4. In the **Session name** field, enter the name of the session you used to connect to the Google service account in the **Connect** action.
5. Optional: Select or create a string variable to hold the output.
The action returns data in JSON format.
6. Click **Save**.

You can use the actions in the **JSON** package to parse the data and extract values from specific nodes. For an overview of how to do this, refer to the following steps:

1. Initiate the JSON session with the **Start session** action. In the **JSON text** field, insert the string variable holding the output of the **Extract** action.
2. Use the **Get node value** action to parse the output of the **Google Document AI > Extract** action and assign the node values to a list variable.

You can insert a **Loop** action after the **Get node value** action to iterate through each list item to perform an operation on each node value.

3. Terminate the JSON session with the **End session** action.

Google Sheets package

The **Google Sheets** package contains actions that enable you to automate tasks involving cells, columns, rows, and sheets.

Before you start

Use the actions in the Google Sheets package in the following order:

1. Use the **Connect** to establish a connection to the Google server.
See [Using the Connect action for Google packages](#) on page 2589.
2. Use a combination of available in this to automate tasks.

Note: To use from other Google , establish a connection using the **Connect** from that .

3. Use the **Disconnect** to terminate the connection.

Actions in the Google Sheets package

The actions in the **Google Sheets** package enable you to perform the following operations:

Action	Description
Activate sheet	See Activate sheet action in Google Sheets on page 2605.
Autofit columns	See Autofit columns action in Google Sheets on page 2605.
Autofit rows	See Autofit rows action in Google Sheets on page 2605.

Related reference

[Google Sheets package updates](#) on page 854

Review the updates in released versions of the Google Sheets package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Activate sheet action in Google Sheets

Activate sheet action enables you to activate a specific sheet in the open spreadsheet.

Settings

Activates a specific sheet in the open spreadsheet.

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** action.
- Specify whether to activate the sheet by index or name.

Note: The sheet index count begins at 1.

Autofit columns action in Google Sheets

Autofit columns action enables you to resize the columns that contain data to accommodate the data.

Settings

Resizes the columns that contain data to accommodate the data. Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** action.

Autofit rows action in Google Sheets

Autofit rows action enables you to resize the rows that contain data to accommodate the data.

Settings

Resizes the rows that contain data to accommodate the data. Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** action.

Close action in Google Sheets

With Close action, you can save and close the current spreadsheet.

Settings

Saves and closes the current spreadsheet. Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** action.

Create sheet action in Google Sheets

Create sheet action enables you to create a new sheet in the open workbook.

Settings

Creates a new sheet in the open workbook.

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- Specify whether to create the sheet by index or name.

Note: The sheet index count begins at 1.

Create workbook action in Google Sheets

Create workbook action enables you to create a new workbook in your Google Sheets.

Settings

Creates a new Google Sheets workbook.

Note: You cannot create a workbook in the Shared with me folder because Google API does not support it.

- Enter the username you used in the **Connect** action.
- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- Enter the workbook name with one of the following file extensions: .xlsx, .xls, or .xlsm
- Enter the file path for the new workbook or select a file variable.

Example

The following example provides information to create a file in Google Drive:

1. Double-click or drag the **Connect** action. See [Using the Connect action for Google packages](#) on page 2589.

Note: When you create bot, replace the values below with yours.

- a) In the **Username** field, select the **Insecure string** option and enter `aatest@gmail.com`
- b) Enter `Default` in the **Session name** field.
- c) In the **Client Id** field, select the **Insecure string** option and enter `55064436-7t68im3caev0941oqa1iae.apps.googleexample.com`.
- d) In the **Client Secret** field, select the **Insecure string** option and enter `b129wCSpmYcwzXg77_D0c`.
- e) Specify the wait time (in minutes) in the **Wait for action to complete (In minutes)** field.
2. Double-click or drag the **Create workbook** action.
 - a) In the **Username** field, select the **Insecure string** option and enter `aatest@gmail.com`
 - b) Enter `Default` in the **Session name** field.
 - c) Enter `Investment plan.xlsx` in the **Workbook name** field.
 - d) For the **File path**, select **From my shared location** option and enter `My Drive/Finance 2023` in the **File Name (optional)** field.
3. Double-click or drag the **Disconnect** action. See [Disconnect action](#) on page 2609
 - a) In the **Username** field, select the **Insecure string** option and enter `aatest@gmail.com`
 - b) Enter `Default` in the **Session name** field.
4. Click **Save** and then **Run**.

Delete cell action in Google Sheets

Delete cell action enables you to delete cells within a worksheet.

Settings

Deletes cells within a worksheet.

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet**.
- Select either the **Active cell** or **Specific cell** option. If you have selected the **Specific cell**, enter the cell address.
- Select from the following delete options:
 - Shift cells left
 - Shift cells up
 - Entire row
 - Entire column

Delete range action in Google Sheets

Delete range action enables you to delete a range of cells.

Settings

Deletes a range of cells.

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- Enter the range address. For example **A1 : B4**.
- Select the direction in which to shift the remaining active cells: **Up** or **Left**.

Delete row/column action in Google Sheets

Delete row/column action enables you to delete a row or column in a worksheet.

Settings

Deletes a row or column in a worksheet.

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- Select whether to perform a row or column operation.
- Specify whether to delete the sheet by index or name.
- Specify whether to delete by index, active cell, or range.
 - If you select index, enter the row/column index

Note: The index count begins at 1.

- If you select range, specify the range of the rows/columns to delete. For example **1 : 10** to delete the first ten rows.

Delete sheet action in Google Sheets

Use the **Delete sheet** action in the Google Sheets package to delete a sheet from a workbook.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- Specify whether to delete the sheet by index or name.

Disconnect action

The Disconnect action terminates the connection with the Google Sheets app. Enter the session name that you used in the **Connect** action. Add this action at the end of automation sequences that use actions from this Google Sheets package.

Settings

- In the **Username** field, you can provide a valid username or select the credential or credential variable that contains your Google username. To enter a value, click **Insecure string**.
- Enter the session name that you used in the **Connect** action.
- Select the check box **Logout from the browser** if you want to sign off from your account.

Format cells action

The **Format cells** action enables you to format specific cells of a workbook.

Settings

- Enter the session name that you used in the **Connect** action.
- Use the **Cell options** field to select one of the following format options:
 - **Active cell**: Is the default selection and is used to format the current or active cell from the workbook.
 - **Specific cell**: Use the **Cell Name** field to enter the name of the cell from the workbook.
 - **Multiple cells**: Use the **Cell range** field to specify the range for of all the cells from the workbook that you want to format.
- (Optional) Select **Font** check box to change the font specifications of the content such as name, size and color.
- (Optional) Select **Alignment** check box to change the vertical or horizontal alignment of the content.
- (Optional) Select **Wrap Text** check box to change the default text wrap option of the content.
- (Optional) Select **Merge Type** check box to choose from various merge options.

Get All Sheet Names action

The **Get All Sheet Names** action enables you to retrieve the names of all the sheets within a specific workbook and store it as a variable.

Settings

- Enter the session name that you used in the **Connect** action.
- Use the **Store All Sheet Names to** field for one of the following options:
 - Select an existing variable from the **Choose a variable** drop-down menu.
 - Click **Create variable** icon for a new variable.

Use the **Create Variable** screen to enter a name, variable type (input or output), and a subtype.

Get Cell/text color action

Use the **Get cell/text color** action to get the color of the background or text in a cell. This action retrieves the color of a cell as RGB values. For example, if the background or text in a cell is of red color, the value retrieved is 255,0,0.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- To get the color from the current active cell, select **Active cell**, or, to get the color from a specific cell, select **Specific cell**.
- Specify the cell name or address in the **Cell name**.
- to get the background color of the cell, select **Cell Color**.
- To get the color of the text, or both, select **Text Color**.
- Specify whether to retrieve the cell color by **Name** or **Code**.
- To assign the cell/text color to a List variable, select one of the options from the **Assign the output to variable** drop-down.

Get Current Sheet Name action

The **Get Current Sheet Name** action for the Google Sheets package enables you to retrieve the name of the current worksheet in a workbook.

Settings

- Enter the session name or select an existing variable used in the **Session name** field.
- In the **Store Current Sheet Name to** field, enter the destination to store the current sheet or select it from the variables.

Get multiple cells action in Google Sheets

Use the **Get multiple cells** action in the Google Sheets package to retrieve values from cells in a Google sheet and store them in a table variable.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet**.
- Select the **Multiple cells** option to retrieve values from a range of cells, or select **All cells** to retrieve values from all cells.
- Select or create a table variable to hold the output.

Get number of rows action

The **Get number of rows** action in the Google Sheets package enables you to get the number of rows that are not empty or contain data.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** action.
- Select the **Non-empty rows** option to get the number of rows that are not empty or the **Total rows with data** option to get the number of rows that contain data.
- Select the number variable from the **Assign output to a variable** field to store the output.

Get single cell action in Google Sheets

Use the **Get single cell** action in the Google Sheets package to retrieve the value from a specific cell in a Google sheet and store it in a string variable.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- Select either the **Active cell** or **Specific cell** option. If you have selected the **Specific cell**, enter the cell address.
- Select or create a string variable to hold the output.

Go to cell action in Google Sheets

Use the **Go to cell** action in the Google Sheets package to go to the specified cell.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- Select a **Cell Options**. If you have selected the **Specific cell** option, enter the cell address. For example, B4.

Hide worksheet action

The Hide worksheet action in the Google Sheets package enables you to hide a worksheet from the current workbook.

Settings

- In the **Worksheet name** field, specify the name of the worksheet to hide.

Note: You can hide a worksheet only if the workbook contains more than one worksheet.

- Enter the name of the session that you used to open the workbook with the **Open spreadsheet** action.

Insert cell action

The **Insert cell** action enables you to insert a cell at a specific point in a workbook by shifting any existing cell.

Settings

- Enter the session name that you used in the **Connect** action.
- Use the **Cell options** field to select one of the following format options:
 - **Active cell:** Is the default selection and is used to format the current or active cell from the workbook.
 - **Specific cell:** Use the **Cell Name** field to enter the name of the cell from the workbook.
- Use the **Shift type** field to select how an existing cell must be shifted.

Insert range action

The **Insert range** action of the Google Sheets package enables you to insert the range into the current worksheet without overwriting the existing value.

Settings

- Enter the session name or select an existing variable used in the **Session name** field .
- Enter the cell range in the **Range address**. For example A1:B4. This inserts a range of cells consisting of the first four rows by the first two columns.

After inserting the cell, set the **Shift type** to **Down** to shift the existing values down by the specified number of rows. Or **Right** to shift the existing values right by the specified number of columns.

Insert row/column action in Google Sheets

Use the **Insert Row/Column** action in the Google Sheets package to insert a blank row or column into a spreadsheet.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- Select whether to insert a row or column.

- If you chose **Row Operations**, select whether to insert the row at a specific index, above the active cell, or in a range.

Note: The index count begins at 1.

- If you chose **Column Operations**, select whether to insert the column at a specific address, to the left of the active cell, or in a range.

Open spreadsheet action in Google Sheets

Use the **Open spreadsheet** action in the Google Sheets package to open an existing spreadsheet.

Settings

- In the **Username** field, enter the same username that you provided in the **Connect** action.
- Enter a session name. Use this session name in subsequent actions to associate them with this spreadsheet.
- Select whether to open the spreadsheet by name, URL, or spreadsheet ID:
 - Name: Enter the file name.
 - URL: Enter the entire URL.
 - Spreadsheet ID: The ID is the value in the URL after the last forward slash. For example, if the URL is `https://docs.google.com/spreadsheets/d/12d1AwvrEA4JeLysfFky9`, the ID is `12d1AwvrEA4JeLysfFky9`.
- If the spreadsheet contains multiple sheets, select the **Specific sheet name** option and enter the sheet name.

Paste cell action

The **Paste cell** action in the Google Sheets package enables you to copy a value from a cell and pastes to a specified cell.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** action.
- Select the **Active cell** or **Specific cell** option to specify the cell from which to read the format. If you have selected the **Specific cell** option, enter the cell name and specify the address of the cell in the field.

Read column action in Google Sheets

Use the **Read column** action in the Google Sheets package to retrieve data from a column and store it in a list variable.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- In the **Cell options** field, specify the cell location from which to read the values. For example, enter A5 to retrieve all the values located in the first column, below the fifth row.
- You can also select the **Read full column** option to extract values from the entire column.
- Select or create a list variable to hold the output.

Read row action in Google Sheets

Use the **Read row** action in the Google Sheets package to retrieve data from a row and store it in a list variable.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** .
- In the **Cell options** field, specify the cell location from which to read the values. For example, enter D5 to retrieve the values located in the fifth row and right of the fourth column.
- You can also select the **Read full row** option to extract values from the entire row.
- Select or create a list variable to hold the output.

Read cell formula action

The Read cell formula action in the Google Sheets package enables you to retrieve the formula available in the **Active cell** or **Specific cell** and assign the output to a string variable. This action returns a blank value if the specified cell does not contain a formula.

Settings

- Enter the name of the session that you used to open the workbook with the **Open spreadsheet** action
- Select the **Active cell** or **Specific cell** option to specify the cell from which to read the formula.

Note: If you have selected the **Specific cell** option, specify the address of the cell in the field.

- In the **Assign the output to variable** field, select a string variable to store the name of the formula. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Rename sheet action

The **Rename sheet** action enables you to rename a specific sheet of a workbook.

Settings

- Enter the session name that you used in the **Connect** action.
- Use the **Sheet** field to select one of the following format options:
 - **Index**: Use this option to select an index that must be renamed.
 - **Name**: Use this option and enter the name of the sheet that you want to rename.
- Use the **Enter new name for the sheet** field to enter a name that must be added.

Retrieve sheets count action

The **Retrieve sheets count** action of the Google Sheets package enables you to get the number of sheets available in the current workbook and store it in a number variable

Settings

- Enter the session name or select an existing variable used in the **Session name** field.
- Select the **Exclude Hidden Worksheets** option to exclude the hidden worksheet or not and assign the count to a variable.
- From the **Assign the output to a variable list** drop-down, specify the variable to which you want to assign the output.

Set cell action in Google Sheets

Use the **Set cell** action in the Google Sheets package to set the value of a specific cell.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet**.
- Enter the address of the cell. For example, A5.
- Select or create a string variable to hold the value of the cell.

Set cell formula action

The **Set cell formula** action of the Google Sheets package enables you to set a formula in the active cell or a specific cell in a Google sheet.

Settings

- In the **Actions** palette, double-click or drag the **Set cell formula** action from the Google Sheets package.
- Use the **Session name** field to enter the name of the session used to open the workbook with the **Open spreadsheet** action.
- Use the **Cell options** field to select one of the following options to specify the cell in which you want to set the formula:
 - **Active cell**: cell that is currently active.
 - **Specific cell**: specify the address of the cell in the **Cell name** field.
(Optional) Click **Insert a value** icon to select an existing variable.
 - **Multiple cells**: specify the range of the cells in the **Cell range** field.
(Optional) Click **Insert a value** icon to select an existing variable.
- Use the **Cell formula** field to enter a formula.
Ensure that you do not use "=".

Set cell or text color action

The Set cell or text color action of the Google Sheets package enables you to set the color of the background or text in a cell. This action sets the color of a cell as RGB values. For example, if you want to set red color to the background or text in a cell, enter the value 255,0,0.

Settings

- Enter the name of the session used to open the workbook with the **Open spreadsheet** action.
- To set the color to the current active cell, select **Active cell**, to set the color to a specific cell, select **Specific cell**, or to set the color to multiple cells select **Multiple cells**.

Note:

- If you have selected the **Specific cell** option, specify the address of the cell in the **Cell name** field.
 - If you have selected **Multiple cells** option, specify the range of the cells in the **Cell range** field.
-
- In the **Set color to** field, to apply color to the background area of the cell, select the **Cell** option. To apply color to the text within a specific cell, select the **Text within cell** option.
 - In the **Cell color by Name/Code** field, specify whether you want to set the cell color by name or as an RGB value or choose a variable that has the value.

Show worksheet action

The **Show worksheet** action in the Google Sheets package enables you to show a hidden google sheet in a worksheet.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet** action.
- Enter the worksheet name in the **Google sheet name** field.

Note: The sheet name should not exceed 31 characters.

Write from data table action in Google Sheets

Use the **Write from data table** action in the Google Sheets package to write the contents of a data table variable to a specific spreadsheet.

Settings

- Enter the name of the session used to open the current spreadsheet with the **Open spreadsheet**.
- Select whether to write to the currently active sheet or to specify a sheet name.
- Select the data table variable.
- Enter the cell address where to start writing the data.

IBM Watson Authentication package

The **IBM Watson Authentication** package contains actions that enable you to authenticate the API token and location URL for each service, while connecting to and disconnecting from your IBM Cloud account. With this package, you only have to provide your credentials once.

Important: This is a beta package and is currently not available with the Automation 360 Enterprise and Cloud editions.

Before you start

Each service requires a unique API key and location URL. Log in to your IBM Cloud account to create an instance of the service to obtain the API Key and location URL. Automation 360 currently includes [Speech to Text](#).

Actions in the IBM Watson Authentication package

Action	Description
Connect	Establishes a connection with the IBM Cloud account. Insert this action at the beginning of automation sequences that use IBM Watson packages so that you have to input the credentials only once. To use this action, select the services to connect with, then provide the API Key and URL for each service you will use.
Disconnect	Terminates the connection with the IBM Cloud account. Insert this action at the end of automation sequences that use IBM Watson packages.

IBM Watson Speech to Text package

This package supports the following audio file formats: flac, mpeg, mp3, ogg, pcm, wav, and webm. The following languages are supported: Arabic, Brazilian Portuguese, Chinese (Mandarin), English (United Kingdom and United States), French, German, Japanese, Korean, Spanish (Argentinian, Castilian, Chilean, Colombian, Mexican, and Peruvian).

Important: This is a beta package and is currently not available with the Automation 360 Enterprise and Cloud editions.

Feature	Description
Detect speakers	<p>Identifies the individuals in a conversation between multiple people.</p> <ul style="list-style-type: none"> • Supports English, Japanese, and Spanish. • Use for conversation between two people; maximum six people. • For best results, use an audio file at least a minute long. <p>The output contains the words spoken by each speaker and the timestamp.</p>
Keyword spotting	Detects specific strings in the transcript. The output contains the timestamp(s) for each keyword and a confidence score.

Feature	Description
Smart formatting	<p>Converts the following types of strings into more conventional representations to make the transcript easier to read:</p> <ul style="list-style-type: none"> • Dates • Times • Series of digits and numbers • Phone numbers • Currency values • Email and web addresses <p>For examples, see Smart formatting results. This feature supports English, Japanese, and Spanish.</p>
Profanity filter	Obscures profanity by replacing it with asterisks in the transcript.

If package

Use the actions in the **If** package to control the sequence of execution based on one or more conditions of a task.

Use the actions in the **If** package to check whether an application is running, a folder or file exists, a variable matches the specified value, an application window exists, or a machine or server is running before executing a set of actions.

Actions in the If package

The **If** package includes the following actions:

Action	Description
If	See If package
Else if (optional)	See Else if (optional) action on page 2626
Else	See Else action on page 2626

Conditions in the If action

Use the following conditions in the **If** action to control the flow of execution in an automation task:

Note: You can add up to a maximum of 32 conditions in a single **If** action.

Condition	Description
Application	<p>Use the Application is running or Application is not running condition to run actions based on whether an application is running or not running.</p> <p>Enter the application path or specify the path using a variable along with the amount of time to wait (in seconds) for the condition to be true.</p> <hr/> <p>Note: The Application is running and Application is not running conditions are not applicable for Internet Explorer bots because its corresponding process <code>iexplore.exe</code> runs in the background when Microsoft Edge is launched in IE mode.</p> <hr/>
Boolean	<p>Use the Boolean variable condition to execute actions based on whether a Boolean variable contains the value True or False.</p> <p>You can also use this condition to compare the values of two Boolean variables by selecting the second variable from the Insert a Variable window.</p>
Data table	<p>Use the Data table is empty condition to execute actions based on whether the specified table contains values.</p> <p>Use the Number of rows and Number of columns conditions to execute actions based on whether the number of columns or rows is Equal to, Greater than, or Less than the specified value.</p>
Datetime	<p>Use the Datetime variable condition to execute actions based on whether the value of the source datetime variable is Equal to or Not Equal to, is Greater than or Equal to, or is Lesser than or Equal to the value of the target datetime variable.</p>
Dictionary	<p>Use the Check key condition to execute actions based on whether the value of the specified key is Equal to or Not equal to, or Contains or Does not contain the target value.</p> <hr/> <p>Note: The key comparison is case-sensitive.</p> <hr/> <p>Use the Check for a single value condition to execute actions based on whether a specific key contains the target value.</p>
DLL	<p>Use the Dll session exists and Dll session does not exist condition to execute actions based on whether a Dll session is open or closed in a bot.</p>

Condition	Description
File	<p>Use the following conditions to execute the action:</p> <ul style="list-style-type: none"> File date Use this condition to verify the date and time when a file was created or modified. Specify a date or date range using the On a date, Is within last, Is between, or Is before options. For the On a date option, specify a date to verify whether the file was created or modified on that date. For the Is within last option, specify the number of days or time (in hours, minutes, and seconds). Enter the amount of time (in seconds) to wait for this condition to be true. File exists and File does not exist Use these conditions to execute an action based on whether a file exists. For example, if a data file exists, format the file and upload it to a database. File extension Use this condition to check the file extension of a selected file and then execute actions based on the results. Use the File path field to select a file. File size This condition verifies if the specified file is larger, smaller, not the same, or the same as the size you specify. Enter the amount of time (in seconds) to wait for this condition to be true.
Folder	<p>Use the Folder exists or Folder does not exist condition to execute an action based on whether a folder exists.</p>
Image Recognition	<p>Use these conditions to verify whether:</p> <ul style="list-style-type: none"> Image file is found in the Image file or not. Image file is found in the Window or not. Window is found in the Image file or not. Window is found in the Window or not. <p>For the Window conditions, you can use the Resize window option to specify the window dimensions. This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the bot's ability to identify the target object.</p> <hr/> <p>Note: This option is only available for windows that can be resized. It is not available for Desktop or Taskbar options.</p> <hr/> <p>For the Window conditions, you can use the Preview option to select a specific captured occurrence and position your click location relative to the image.</p>

Condition	Description
JavaScript	Use the Script is successful or Script is unsuccessful condition to execute actions based the status of the specified JavaScript. Select the file that contains the script and optionally specify the parameters by selecting a list variable.
Legacy automation	<p>The Legacy automation conditions are only used in migrated bots to ensure that they run seamlessly in Automation 360. We do not recommend using these conditions for new bot development. The following conditions to verify the following:</p> <ul style="list-style-type: none"> • Whether Web control exists or not. • Whether Window control exists or not. • Whether Window control is active or not. • Whether Script is successful or not. • Whether Child window exists or not. <p>For the Window control conditions, you can use the Resize window option to specify the window dimensions. This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the bot's ability to identify the target object.</p>
List	Use the List variable condition to execute actions based on whether the specified list variable contains a particular value. The value can be of Number , String , or Boolean data type.
Number	Use the Number variable condition to execute actions based on whether the specified number variable is Equal to or Not Equal to , or is Greater than or Equal to , or is Lesser than or Equal to a particular value.
Ping	Use the Ping is successful or Ping is unsuccessful condition to verify if a machine or server is running, and execute actions based on the result. Enter the amount of time (in seconds) to wait for the condition to be true.
Recorder	<ul style="list-style-type: none"> • Use the Object exists condition to detect an object in a window. Select a window or variable to capture the object. Enter the amount of time (in seconds) to wait for this condition to be true, that is, for the object to be detected. • Use the Object does not exist condition to verify whether a specific object exists in a window, and then based on the result, execute actions. Enter the amount of time (in seconds) to wait for this condition to be true. For example, you can use the Object does not exist condition inside the Loop > While condition to make sure that the bot does not execute the next action until the object on the business application is loaded. <hr/> <p>Note: The Object exists and Object does not exist Recorder conditions support Chromium-based Microsoft Edge with Internet Explorer mode.</p> <hr/>

Condition	Description
Service	Use the Service is running or Service is not running condition to execute actions based on whether a service is running or not. Select Service list to choose a service from the list of available services.
String	<p>Use the String variable condition to execute actions based on whether the specified source string value is Equal to or Not equal to, or Includes or Does not include the target value.</p> <p>You can select the Match case option to only execute actions if the two strings have matching uppercase and lowercase letters.</p> <p>When you extract text from a Microsoft application, the extracted text contains the /r/n special characters which indicate a new line. Select the Ignore Carriage return option if you want to ignore the /r special character when you compare the text.</p> <p>To create a condition based on whether a string is empty or not empty, compare the source value to an empty target field using the Equal to operator.</p> <p>See Example of using a conditional statement on page 3078.</p>
Task Bot	Use the Task successful or Task unsuccessful condition to execute actions based on the status of the specified Task Bot.
VBScript	Use the Script is successful or Script is unsuccessful condition to execute actions based on the status of the specified Visual Basic script. Select the file that contains the script and optionally specify the parameters by selecting a variable.

Condition	Description
Window	<p>Use the Window exists or Window does not exist condition to verify if a specific application window is open by entering the Window title or using a variable. Enter the amount of time (in seconds) to wait for the condition to be true. These conditions are used when the window title remains constant and to verify if the specific window is open and execute further actions based on the output.</p> <p>The Window exists condition uses the same window variable to search the specific window from cache. For example, when you open a <code>Yahoo India</code> web page and perform a Click action on the News option on the web page, the action navigates you to another page which changes the title of the window. In this case, when you use the Window exists condition to verify if the window exists, the bot still fetches the <code>Yahoo India</code> web page from the cache and performs action on it because the window is still the same but only the title has changed. For more information on how window variables work, see Your variables (user-defined) on page 2241</p> <p>Use the Window with same title does not exist or Window with same title exist condition to verify whether a window with the same title exists or whether the window title has changed. Enter the amount of time (in seconds) to keep verifying if the condition is true. These conditions are used for window titles that are dynamic. For example, when you open a Google account webpage, enter your username and password to log into your account, the window title changes. If you want to compose a new email as a next action, you can use these conditions before you execute the next action to verify if the window with the same title exists or if the title has changed.</p>

Group conditions

Use the **Add group** option to add multiple Boolean conditions or combine more than one conditions with **And** and **Or** options within a group and when you want the to check multiple conditions at a time before executing a set of .

You can also add a group within a group.

Example

[Build a basic bot that uses a desktop application](#) on page 3069

An example of how to build a basic TaskBot that uses the If package.

Related reference

[If package updates](#) on page 856

Review the updates in released versions of the If package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

If action

The If action in the If package enables you to specify a condition and hold a sequence of actions to run if the condition is true.

Settings

You can configure multiple conditions within a single **If** action.

1. Click **Add condition**.
2. Select either of the following options:
 - **And**: Both of the conditions must be met for the to run.
 - **Or**: Either of the conditions must be met for the to run.
3. Select the condition from the drop-down list.

See [Using If action](#) on page 2625.

Using If action

Use the **If Else If** and **If Else** actions to change the flow of execution in an automation task based on certain conditions.

To use the actions in the **If** package, do the following:

1. Double-click or drag the **If** action from the **If** package in the **Actions** palette.
2. Select the required condition from the **Condition** list.
See [If package](#) on page 2619 for a list of available conditions.
3. Drag the actions to be executed if the condition is satisfied within the **If** condition.
4. Double-click or drag the **Else If** action from the **If** package in the **Actions** palette to include alternative actions to run if the condition for the **If** action is false, and if the condition for the **Else If** action is true.
5. Drag the actions to be executed if the condition is satisfied within the **Else If** condition.
6. Double-click or drag the **Else** action from the **If** package in the **Actions** palette to include actions to run if the conditions for the **If** and **Else If** actions are false.
7. Drag the actions to be executed if the condition is satisfied within the **Else** condition.
8. Click **Save**.

Else if (optional) action

The Else if (optional) action in the If package enables you to specify an alternative condition to test if the condition specified in the If action is false.

Settings

If this alternative condition is true, the bot runs the sequence of actions contained within the **Else if** action.

You can configure multiple conditions within a single **Else if** action.

1. Click **Add condition**.
2. Select either of the following options:
 - **And**: Both of the conditions must be met for the to run.
 - **Or**: Either of the conditions must be met for the to run.
3. Select the condition from the drop-down list.

Else action

The Else action in the If package enables you to specify the alternative sequence of actions.

Settings

Specifies the alternative sequence of actions if the condition specified in the If action and **Else if** action (if used) is false.

Image Recognition package

The **Image Recognition** package contains actions that enable you to search for a user interface (UI) element in an application based on an image to automate a task in that application.

Actions in the Image Recognition package

Use these actions to automate a task when it is not possible to capture UI elements of applications that are:

- Exposed over Citrix
- Accessed using the Remote Desktop Protocol (RDP)
- Developed using legacy technology

Image recognition is also useful when object-based recognition does not work or is unreliable. For example, you can use an image to search for the **Close** button in an application and perform a left-click operation.

The **Image Recognition** package contains the following actions:

Action	Description
Find image in window	See Using Find image in window action on page 2627.
Find window in window	See Using the Find window in window action on page 2630.

Secure recording

When secure recording mode is enabled, bots display only the target image but not the source image. This ensures that sensitive data is not shown. To see a preview of the source image in the **Preview** window, click the **Preview** button.

Note: The target images are still stored in the Control Room because they are required to run the bots.

A user with admin privileges must enable this setting. See [Settings](#) on page 1728.

Secure recording

When secure recording mode is enabled, bots do not display the target object images after capture. This ensures that sensitive data is not shown.

Note: Although the bots do not display the target images after capture, the images are still stored in the Control Room because they are required to run the bots.

When you record a task in secure recording mode, the **Preview** window temporarily shows an image of the captured area. This image is hidden after you navigate away from the Bot editor window or refresh it.

A user with admin privileges must enable this setting. See [Settings](#) on page 1728.

Related reference

[Screen resolution dependent packages](#) on page 1739

The screen resolution between the Bot Runner and Bot Creator device should be consistent as when resolution-dependent packages are used to build bots, any screen resolution difference between the Bot Creator and Bot Runner device will impact the bots during runtime.

[Image Recognition package updates](#) on page 857

Review the updates in released versions of the Image Recognition package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using Find image in window action

Use the **Find image in window** action to search for a UI element in an application window (haystack) using a target image (needle). The target image is an existing image that you can use to search for a UI element.

To find an image inside an application window, follow these steps:

1. Double-click or drag the **Find image in window** action from the **Image Recognition** package in the **Actions** palette.
2. Specify the target image (needle) that you want to find in the application window.
 - **Control Room file**: Uses an image file that is available on the Control Room.
 - **Desktop file**: Uses an image file that is available on your device.
 - **Variable**: Uses a file variable to specify the location of the image file you want to use.

Note: Images of .jpeg, .jpg, .jpe, .jfif, .bmp, .png, and .gif formats are supported.

3. Specify the window in which you want to find the source image (haystack):
Choose from the **Application**, **Browser**, or **Variable** tab.

Option	Description
Application	Select from a list of currently active windows. This option shows a list of all the application and browser windows that are open on the Bot Creator device.
Browser	Select from a list of supported browser tabs. Note: This option supports , Chromium-based , and browsers. For all other browsers, use the Application option.
Variable	Select an existing window variable to specify the title of the application window title.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*) -Notepad` for all window title names starting with `((\w*) -Notepad`, or use **Pattern** value as `((\w) \s) *document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error,

ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.

- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

-
4. Optional: Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.

- If the window is maximized when you record the task, this option is not selected.
- If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

5. Click **Capture region**.

The selected window appears.

6. Drag the mouse to select the area and right-click when done.

The captured area appears in the **Preview** section with the image coordinates underneath.

7. In the **Wait in ms before capturing the image** field, specify the delay (in milliseconds) before searching for the image.

8. Select the **Repeat if image not found** check box if you want the system to retry searching for the target image if it is not found.

- a) In the **Times** field, specify the number of times the system must repeat the process to find the target image.

- b) In the **Wait between repeats (ms)** field, specify the time period the system must wait before repeating the process of finding the target image.

9. In the **Match percentage** field, specify the acceptable percentage of matching pixels between the two images.

For example, if you specify 20 in the field as the match percentage, the system considers the images as matching even if there is up to 80% of pixel mismatch between the two images.

10. In the **Selected match number** field, enter a value to specify the occurrence of the target image on which you want to perform this action.

You can insert a variable when you do not know the number of times the image might appear on the screen. Ensure you assign variables that support numeric values.

11. Use the **Preview** option if you want to select an image that is relative (offset) to the existing target image you are searching on the application screen, or you want to select a specific occurrence if there are multiple occurrences of the target image.

12. Click **Preview**.

If a target image occurs multiple times in the **Preview** window, each occurrence is highlighted in a rectangular box and displays a number against each occurrence.

13. Select the specific highlighted occurrence, and you can position your click location relative to an existing image.

Note: If there are multiple images on an application screen that you are automating and when the target image is not easily searchable; in that case, you can select an easily identifiable image in the captured region and position your click relative to it.

14. If the target image is found multiple times in the captured region. In that case, you can select the occurrence of a particular target image or select the occurrence number from the drop-down in the **Match number (optional)** field on the right pane.

The **Match number (optional)** and the **Target Offset** fields on the right pane display the image occurrence you selected and its offset coordinates of the target image.

15. Click **Submit**.

16. In the **Target coordinate selections** field, the coordinate options **Center of match** or **Offset from match** will be selected automatically based on the action you performed in the **Preview** window.

- **Center of match:** The image is selected based on the coordinates at the center of the matched image.
- **Offset from match:** The image is selected based on the coordinates relative to that of the matched image.

Note: The offset coordinates measure the number of pixels from the top left corner of the image.

17. Select an option from the **Action to take on target coordinates** list to specify the action you want to perform on the matched image in the application window.
18. Click **Save**.

Using the Find window in window action

Use the **Find window in window** action to search for a UI element in an application window using a screenshot of a window. This action enables you to capture an image of a UI element in an application and use the captured image to search for that UI element in another window.

To use an image available in an application window to find an image in another application window, follow these steps:

1. Double-click or drag the **Find image in window** action from the **Image Recognition** package in the **Actions** palette.
2. Specify the target image (needle) that you want to find in the application window.

Option	Description
Browser	Select from a list of supported browser tabs. Note: This option supports , Chromium-based , and browsers. For all other browsers, use the Application option.
Application	Select from a list of currently active windows. This option shows a list of all the application and browser windows that are open on the Bot Creator device.

You can use a regular expression (regex) to identify a window title. Select the regular expression either as a **String** or **Pattern** for each regular expression condition and enter the value. By default, the **Window title** field is case-sensitive. You can enable **Case insensitive** regex flag to identify a window title that is not case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

3. Click **Capture image** to capture the target image.
4. Drag the mouse pointer over an area of the application window.
The captured area appears in the **Preview** section.
5. Specify the window in which you want to find the source image (haystack):
Choose from the **Application**, **Browser**, or **Variable** tab.

Option	Description
Application	Select from a list of currently active windows. This option shows a list of all the application and browser windows that are open on the Bot Creator device.
Browser	Select from a list of Google Chrome tabs that are currently open on the Bot Creator device. Note: Currently, this option only supports Google Chrome tabs. For all other browsers, use the Application option.
Variable	Select an existing window variable to specify the title of the application window title.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value.

For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The bot first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression either as a **String** or **Pattern** for each regular expression condition and enter the value. By default, the **Window title** field is case-sensitive. You can enable **Case insensitive** regex flag to identify a window title that is not case-sensitive. You can enable the **Case sensitive** option to identify a static window or browser title and a title with a wildcard character that is case-sensitive and disable the option to identify a window title that is not case-sensitive.

For example, you can enter the **String** value as `((\w*)-Notepad)` for all the window title names starting with `((\w*)-Notepad)`, or use **Pattern** such as `((\w)\s)*document-Notepad` for only those window titles that match this pattern.

6. Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the bot's ability to identify the target object.

- If the window is maximized when you record the task, this option is unselected.
- If the window is not at the maximum size when you record the task, this option is selected by default and the width and height fields auto-fill with the window dimensions.

Note: This option is only available for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

7. Click **Capture region.**

The selected window appears.

8. Drag the mouse to select the area and right-click when done.

The captured area appears in the **Preview** section with the image coordinates underneath.

9. In the **Wait in ms before capturing window field, specify the delay (in milliseconds) before searching for the image.**

10. Select the **Repeat if image not found check box if you want the system to retry searching for the target image if it is not found.**

a) In the **Times** field, specify the number of times the system must repeat the process to find the target image.

b) In the **Wait between repeats (ms)** field, specify the time period the system must wait before repeating the process of finding the target image.

11. In the **Match percentage field, specify the acceptable percentage of matching pixels between the two images.**

For example, if you specify 20 in the field as the match percentage, the system considers the images as matching even if there is up to 80% of pixel mismatch between the two images.

12. In the **Selected match number field, enter a value to specify the occurrence of the target image on which you want to perform this action.**

You can insert a variable when you do not know the number of times the image might appear on the screen. Ensure you assign variables that support numeric values.

13. Use the **Preview option if you want to select an image that is relative (offset) to the existing target image you are searching on the application screen, or you want to select a specific occurrence if there are multiple occurrences of the target image.**

14. Click **Preview.**

If a target image occurs multiple times in the **Preview** window, each occurrence is highlighted in a rectangular box and displays a number against each occurrence.

15. Select the specific highlighted occurrence, and you can position your click location relative to an existing image.

Note: If there are multiple images on an application screen that you are automating and when the target image is not easily searchable; in that case, you can select an easily identifiable image in the captured region and position your click relative to it.

16. If the target image is found multiple times in the captured region. In that case, you can select the occurrence of a particular target image or select the occurrence number from the drop-down in the **Match number (optional) field on the right pane.**

The **Match number (optional)** and the **Target Offset** fields on the right pane display the image occurrence you selected and its offset coordinates of the target image.

17. Click **Submit**.
18. In the **Target coordinate selections** field, the coordinate options **Center of match** or **Offset from match** will be selected automatically based on the action you performed in the **Preview** window.
 - **Center of match**: The image is selected based on the coordinates at the center of the matched image.
 - **Offset from match**: The image is selected based on the coordinates relative to that of the matched image.

Note: The offset coordinates measure the number of pixels from the top left corner of the image.

19. Select an option from the **Action to take on target coordinates** list to specify the action you want to perform on the matched image in the application window.
20. Click **Save**.

Interactive forms package

The interactive forms package contains actions that handle exceptions encountered by a bot. All the actions performed by users on the interactive forms can be monitored to execute logic using subtasks.

Interactive forms are first-class citizens within the bot repository and have the same workflows for moving forms between public and private workspaces, and for export or import actions. Handling exceptions ensures that a bot completes a task when it encounters an error.

Actions in the Interactive forms package

The interactive forms package includes form-level and element-level actions.

The following actions are available at the form level:

Action	Description
Display	Load and display the selected form. Select or insert a variable in the Form name field to display the form when an event is triggered. Optionally, select the check box to always display the form window in front.
Close	Closes the selected form.
Show	Loads or displays a hidden form. Select or insert a variable in the Form name field for a hidden form, which is displayed on the desktop when an event is triggered.
Hide	Hides the selected form from the user's view.
Reset	Resets the selected form to its default value. Select or insert a variable in the Form name field for a form. All the values of this specified form are reset when an event is triggered.

Action	Description
Validate form	<p>Validates all the elements within the selected form.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field for a specific form, which is validated when an event is triggered. • Select the next event by creating or selecting a variable using the Assign the return value to a boolean variable field. <hr/> <p>Note: The Validate form action is not applicable to Rich Text Editor elements.</p> <hr/>
Change Form Title	<p>Changes the title of the selected form.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field for a specific form. • Enter the new title that must appear for the selected form in the New Title (optional) field.

The following actions are available at the element level:

Action	Description
Assign	<p>Assigns dynamic values to the Dropdown element of a form.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field. • Select the Dropdown element of the form from the Form element field, which is enabled when an event is triggered. • Use Assign to set one of the following actions: <ul style="list-style-type: none"> • Append: Specified values or variables are added to the selected Dropdown element. • Overwrite: Specified values or variables replace the existing data in the selected Dropdown element. <hr/> <p>Note: The Assign action is now applicable for the Checkbox and Radio Button elements in interactive forms.</p> <hr/>
Enable	<p>Enables the specified element of the selected form.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field. • Select a specific element of the form from the Form element field, which is enabled when an event is triggered.
Disable	<p>Disables the specified element of the selected form.</p>

Action	Description
Get	<p>Retrieves the value from the specified element of the selected form.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field and use the Form element to select a specific element of the form. • Use the Returns the value drop-down menu to assign this value to a variable when an event is triggered. <p>Create a variable on page 2246</p>
Set	<p>Assigns the user-defined or global variable to the selected element of the specified form.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field and use the Form element to select a specific element of the form. <p>If you select Table as the Form element, use the Set Value Type to enable the following additional options:</p> <ul style="list-style-type: none"> • Table: Sets the variable value to the entire table. • Row: Sets the variable value to the selected row. • Use the Input value to assign a user-defined or system variable into this element when an event is triggered.
Set focus	<p>Sets the focus on the selected element of a form.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field. • Use the Form element to select the specific element of the form and set the focus: <ul style="list-style-type: none"> • For form elements such as a text box, text area, number or date, the cursor appears on the element. • For form elements such as a check box or radio button, the emphasis is on the first option.
Highlight	<p>Highlights the specified element of the selected form.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field. • Use the Form element to select the specific element of the form to highlight it when an event is triggered. • Use the Highlight Type drop-down menu to select one of the following: <ul style="list-style-type: none"> • Warning: Displays a warning alert on the specified form element. • Error: Displays an error alert on the specified form element.
Unhighlight	<p>Removes the highlight from the specified element of the selected form.</p>

Action	Description
Change label	<p>Changes the label of the selected form element.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field. • Use the Form element to select the specific element of the form for which the label must change when an event is triggered. • Enter the name in New label field. <hr/> <p>Note: The Change label action is now applicable for Button elements in interactive forms.</p> <hr/>
Dynamic area	
Add row in Dynamic area	<p>Applies only to forms that have a Dynamic element. This action renders the selected form field as a single row when the bot starts.</p> <ul style="list-style-type: none"> • Select or insert a variable in the Form name field. • Use the Dynamic area drop-down menu to select the dynamic element of the form. • Use Append or Overwrite to add a row for the specified dynamic area. • Use Add element to insert elements into the dynamic area. <ul style="list-style-type: none"> • Use the Type drop-down menu to select the element type such as Checkbox group, Drop-down, File, Radio group, Snapshot, Text area, or Textbox. • Use the Label field to enter a name for the element. • Click Add to add the element. <p>You can add up to four elements.</p>
Clear	Clears all the dynamic elements in the specified form.

IQ Bot Pre-processor package

Use the IQ Bot Pre-processor package to extract content from documents or process image files before they are sent to Automation 360 IQ Bot.

Windows Media Foundation platform must be installed on your Bot Runner machine in order to use the following actions without any errors.

Actions in the IQ Bot Pre-processor package

The following table lists the actions used for processing image file:

Actions	Description
Concatenate Images	See Using Concatenate Images action on page 2637

Actions	Description
Convert Image To PDF	See Using Convert Image To PDF action on page 2638
Edit Image	See Using Edit Image action on page 2638
Enhance Image	See Using Enhance Image action on page 2640
Orient Image	See Using Orient Image action on page 2644

The following table lists the actions used for extracting content from documents:

Actions	Description
Get Bar Codes	See Using Get Bar Codes action on page 2639
Get Document Info	See Using Get Document Info action on page 2639
Get Page Content	See Using Get page content action on page 2640

To learn more, review the courses in IQ Bot Developer learning trail: [IQ Bot Developer Training \(A-People login required\)](#).

Using Concatenate Images action

Use the **Concatenate Images** action in the IQ Bot Pre-processor package to link two image files.

1. Drag the **IQ Bot pre-processor > Concatenate Images** action into your workflow.
2. Use the **Input file path 1** field to select the first input file from **Control Room file**, **Desktop file** or **Variable**.
3. Optional: If you selected **Control Room file** or **Desktop file**, click **Browse** to change the default filepath.
4. Use the **Input file path 2** field to select the second input file.
5. Select the output folder from the **Output Path** field.
6. Optional: Click **Browse** to change the default output filepath.
7. Use the **Concatenate Type** field to select one of the following options:
 - **Vertical**: To vertically concatenate or link the selected images.
 - **Horizontal**: To horizontally concatenate or link the selected images.
8. Optional: Use the **Assign output status to variable** field to set the output status of action during bot runtime.
9. Click **Save**.
When the bot runs successfully, the combined image file is saved in the specified output folder.

Using Convert Image To PDF action

Use the **Convert Image To PDF** action in the IQ Bot Pre-processor package to convert a selected image file to a text-enabled PDF document. The converted PDF file retains the name of the input image file by default.

1. Drag the **IQ Bot pre-processor > Convert Image To PDF** action into your workflow.
2. Select the input file from **Control Room file**, **Desktop file** or **Variable**.
3. Optional: If you selected **Control Room file** or **Desktop file**, click **Browse** to change the default filepath.
4. Use the **Output Path** field to select the output folder for the PDF document.
5. Optional: Click **Browse** to change the default output filepath.
6. Optional: Choose from the following advance settings:
 - **Input file settings**: Use this field to select various input file settings.
For example, if the input file is a legal document (a bank check), select the **Has MICR** check box.
 - **Process settings**: Use this field for processing the output file.
For example, select the **Process text blocks independently** check box if the OCR engine must process various blocks of the input file as a specific text type.
7. Optional: Use the **Save the output status of the action as boolean** to set the output status.
8. Click **Save**.
When the bot runs successfully, the processed PDF file is saved in the specified output folder.

Using Edit Image action

Use the **Edit Image** action in the IQ Bot Pre-processor package to resize an image file.

1. Drag the **IQ Bot pre-processor > Edit Image** action into your workflow.
2. Select the input file from **Control Room file**, **Desktop file** or **Variable**.
3. Optional: If you selected **Control Room file** or **Desktop file**, click **Browse** to change the default filepath.
4. Use the **Output Path** field to select the output folder.
5. Optional: Click **Browse** to change the default output filepath.
6. Use the **Select Image Edits** drop-down menu to select one of the following options:
 - **Crop**: Use an auto-crop or manual option to crop the image.
 - **Resize**: Change the height and width of the image.
7. Optional: Use the **Assign output status to variable** field to set the output status of action during bot runtime.
8. Click **Save**.
When the bot runs successfully, the edited image file is saved in the specified output folder and is suffixed by the word processed.

For example, if the image filename is `Sales.png`, the processed file is saved as `Sales_processed.png`

Using Get Bar Codes action

Use the **Get Bar Codes** action in the IQ Bot Pre-processor package to detect and extract all available barcodes from a document.

1. Drag the **IQ Bot pre-processor > Get Bar Codes** action into your workflow.
2. Select the input file from **Control Room file**, **Desktop file** or **Variable**.
3. Optional: If you selected **Control Room file** or **Desktop file**, click **Browse** to change the default filepath.
4. Use the **List of dictionaries with 7 keys** drop-down menu to select the output format for the extracted strings.

If the document has multiple barcodes, multiple dictionaries are used as each dictionary corresponds to a single barcode. Each dictionary has the following seven keys that relate to the various attributes of the barcode in a document:

- Page number of the document where a barcode is available
- Type of the barcode
- Value of the barcode
- X coordinate of the barcode
- Y coordinate of the barcode.
- Width of the barcode
- Height of the barcode

5. Click **Save**.
When the bot runs successfully, the extracted barcodes are assigned to the output variable.

Using Get Document Info action

Use the **Get Document Info** action in the IQ Bot Pre-processor package to extract document information such as the page count and extension type.

1. Drag the **IQ Bot pre-processor > Get Document Info** action into your workflow.
2. Select the input file from **Control Room file**, **Desktop file** or **Variable**.
3. Optional: If you selected **Control Room file** or **Desktop file**, click **Browse** to change the default filepath.
4. Use the **Dictionary object with 5 keys** drop-down menu to select the output format for the extracted information.

Each dictionary has the following five keys that relate to the various attributes of the document:

- Filepath of the document location
- Extension type of the document
- File type of the document
- Total number of pages in the document
- File size of the document

5. Click **Save**.
When the bot runs successfully, all the extracted information for the selected document is assigned to the output variable.

Using Get page content action

Use the **Get page content** action in the IQ Bot Pre-processor package to extract text from a specific page of a document (PDF, image file) into a list of strings.

1. Drag the **IQ Bot pre-processor > Get page content** action into your workflow.
2. Select the input file from **Control Room file**, **Desktop file** or **Variable**.
3. Optional: If you selected **Control Room file** or **Desktop file**, click **Browse** to change the default filepath.
4. Enter the page number of the selected document from which the content must be extracted.
5. Use the **List of strings extracted from page** drop-down menu to select the output format for the extracted strings.

You can use this menu to create a variable with **Type > List** and **Subtype > String**. Alternatively, you can select an existing variable with **Type > List**, and **Subtype > String** or **Subtype > Any**.

6. Click **Save**.
When the bot runs successfully, the content extracted from the specific page of the selected document assigned to the output variable.

Using Enhance Image action

Use the **Enhance Image** action in the IQ Bot Pre-processor package to enhance a selected image file.

1. Drag the **IQ Bot pre-processor > Enhance Image** action into your workflow.
2. Select the input file from **Control Room file**, **Desktop file** or **Variable**.
3. Optional: If you selected **Control Room file** or **Desktop file**, click **Browse** to change the default filepath.
4. Use the **Output Path** field to select the output folder.
5. Optional: Click **Browse** to change the default filepath.
6. Optional: Click **Add effect** and use **Effect type** drop-down menu for image enhancement options.

For more information on the available options, see [Image enhancement options in Enhance Image action](#) on page 2641.

Consider a scenario where you have uploaded a low quality image. Use the following options to improve the clarity and increase the brightness:

- Select **Effect type > SHARPEN**.

Additional fields associated with sharpening an image such as Gaussian blur, Alpha, Beta and Gama are displayed.

- For this example, enter 5 in the **Alpha** field.

Value between 0 to 10 can be used in the additional fields. Optionally, you can also press F2 or click **Insert a value** option to select a system value.

- Select **Effect type > BRIGHTNESS**.
- Enter 7 in the **Brightness factor** field.

The selected enhancement options are listed in the **Effect type** field, and you can edit or delete a specific effect type.

7. Click **Add**.
8. Optional: Use the **Assign output status to variable** field to set the output status of action during bot runtime.
9. Click **Save**.
When the bot runs successfully, the enhanced image file is saved in the specified output folder.

Image enhancement options in Enhance Image action

Improve the quality of an image that you have uploaded in the **Enhance Image** action by using additional options available.

Option	Use
Grayscale	Convert the color pixels in an image to grayscale. Recommended: Convert color images to grayscale to improve the OCR extraction accuracy.
Blur	Smoothen out areas that are pixelated and improve image quality. Recommended values: Any odd number (such as 3, 7, and 11), as long as it is less than the pixel size of the uploaded image.

Option	Use
Sharpen	<p>Improve clarity by removing distorted and blurred aspects of the original image.</p> <p>Consider a scenario where you have an image file called ImageA. When you apply Gaussian blur = 5 to this image, a blurred version of this image is created called ImageB. You can then use the following Sharpen parameters:</p> <ul style="list-style-type: none"> • Alpha: 3 • Beta: -1 • Gamma: 0 <p>The following formula is applied for output:</p> $\text{Output} = \text{ImageA} * \text{Alpha} + \text{ImageB} * \text{Beta} + \text{Gamma}$ <p>Where:</p> <ul style="list-style-type: none"> • ImageA: First input array (Input image) • Alpha: Weight of the first array elements • ImageB: Second input array image with the same size and channel number as ImageA • Beta: Weight of the second array elements • Gamma: Scalar added to each sum <hr/> <p>Note: The principal use of the preceding equation is to sharpen an image by removing the blurriness from the original image.</p> <hr/> <p>Recommended values:</p> <ul style="list-style-type: none"> • Gaussian blur: 0 to 10 • Alpha: 1 to 15 • Beta: -0.5 to -5 • Gamma: 0 to 50
Denoise	<p>Smoothen out pixels that are not grayscale to remove distortion or speckling from the image.</p> <p>Recommended value: 21. However, it can be any odd number as long as it is less than the pixel size of the uploaded image.</p>
Contrast	<p>Increase or decrease the contrast of the pixels. Values can range from 0 (no change) to 2 (maximum contrast).</p> <p>Recommended values: From 0.8 through 2.</p>
Brightness	<p>Increase or decrease the brightness level of all the pixels in the image. Values can range from -100 (minimum contrast) to 100 (maximum contrast), with 0 representing no change.</p> <p>Recommended values: From 0 through 100</p>

Option	Use
<p>Thresholding</p>	<p>A form of image segmentation. Thresholding is an image processing method that creates a bi-tonal (binary) image by setting a threshold value on the pixel intensity of the original image. In image processing, thresholding is typically used to separate objects or foreground pixels from background. For example, the following image has been processed using Thresholding value as 200 and 100 respectively.</p> <div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;">  </div> <div style="text-align: center;">  </div> <div style="text-align: center;">  <p>Thresholding Value: 200</p> </div> </div> <div style="display: flex; justify-content: space-around; align-items: center; margin-top: 20px;"> <div style="text-align: center;">  </div> <div style="text-align: center;">  </div> <div style="text-align: center;">  <p>Thresholding Value: 100</p> </div> </div> <p style="text-align: center; margin-top: 10px;">Recommended value: From 0 through 255</p>
<p>Remove RGB</p>	<p>Provide upper and lower bound values to pixels in a color image. Pixels in a color image are represented by three primary color channels: red, green, and blue (RGB). The output of this effect is a binary image with pixels that are black (0) or white (255). Consider a scenario where you want to transform high-intensity red pixels in the range of 200 to 255 to white (255). You can set the lower bound for red to (200,0,0) and upper bound to (255,0,0).</p>

Using Orient Image action

Use the **Orient Image** action in the IQ Bot Pre-processor package to change the orientation of a selected image file.

1. Drag the **IQ Bot pre-processor > Orient Image** action into your workflow.
2. Select the input file from **Control Room file**, **Desktop file** or **Variable**.
3. For the **Control Room file** and **Desktop file** tabs, click **Browse** to change the default filepath.
4. Use the **Apply settings** field to change the following orientation options:
 - **Flip**: Use the drop-down menu to flip the image horizontally, vertically, or horizontally and vertically.
 - **Rotate**: Use the drop-down menu to:
 - Rotate the image clockwise or anti-clockwise.
 - Change the angle of the image.

For example, enter 45 if you want to change the image angle by 45 degrees.

5. Click **Save**.
When the bot runs successfully, the modified image file is saved in the specified output folder.

IQ Bot Extraction package

Capability to automatically extract values provides enhanced content extraction from invoices.

Learning instance is an IQ Bot environment that enables you to train sample documents for content extraction. By constantly refining the learning instance, you can achieve a high content extraction accuracy before deploying the learning instance across a production environment.

IQ Bot Extraction package combines learning instance (new or existing) and a pretrained machine learning model to automatically extract content. The pretrained machine learning model uses data points to extract content from the supported document types. By providing additional training to an existing learning instance, you can extract content from other document types as well.

Note: This package is deprecated from Automation 360 v.26. IQ Bot Document Automation provides all the capabilities provided by the IQ Bot Extraction package. To move your bots from the IQ Bot Extraction package to Document Automation, see [Move from IQ Bot Extraction package to Document Automation](#) on page 2647.

The following diagram shows the IQ Bot Extraction package workflow:

Contact your Customer Success Manager (CSM) or Partner Enablement Manager (PEM) for more information on the high level architecture, design and folder structure.

[High level architecture, design overview, folder structure of IQ Bot Extraction package \(A-People login required\)](#)

IQ Bot Extraction package provides the following extraction methods:

Content extraction with minimum training

The IQ Bot Extraction package is designed to extract values with minimum training from specific document type such as an invoice or purchase order.

Note: For this content extraction method, ensure you always use the ABBYY FineReader Engine OCR 12.4 engine.

Consider a scenario where you want extract sales data from various invoices. Create a learning instance by selecting a pretrained domain or document type used to extract data. In this scenario, you can select the document type as invoice, which provides a set of preset fields for content extraction. Ensure you upload a sample invoice document as a reference. Additional training of the learning instance group is not required. Use the IQ Bot Extraction package to link this learning instance to a bot. You can then run this bot to retrieve sales data based on the preset fields for various invoices.

Enhanced extraction with additional training

The IQ Bot Extraction package uses a combination of backend engine with IQ Bot server for enhanced document extraction. You can use an existing learning instance to provide additional training for all the available document groups. By customizing the various fields and validation settings of the learning instance group, you can use this package content extraction across other document types.

Important: This package is not available as part of the standard Automation 360 IQ Bot installation. To download and install this package, perform these steps:

1. Download the package from the Automation Anywhere support site. The package is a .jar file available in the IQ Bot **Installation Setup** folder.

[A-People Downloads page \(Login required\)](#)

2. Upload the package to Control Room.

[Add packages to the Control Room](#) on page 1842

Before you start

- Ensure you create a learning instance using a supported OCR.
- Select documents with common layouts.

The preset model contains logical group. It is important to select an existing group for default validation rules to avoid documents with errors in the Success folder.

- Ensure that the Bot Agent version is not older than the previous two versions.

For example, if you upgrade to Automation 360 v.23 Build 11513 (On-Premises), ensure that the Bot Agent version is not older than 21.82.10342.

See [Bot Agent compatibility](#) on page 1274.

Action in the IQ Bot Extraction package

The following action is available to build a bot for extracting data:

Action	Description
IQ Bot Extraction	See Using IQ Bot Process documents action on page 2652.

Watch the following video to understand how to use the IQ Bot Extraction package:

Related tasks

[Select an OCR engine](#) on page 3557

You can select an OCR engines that suits your requirement for data extraction based on your document types. Restarting IQ Bot services is not necessary for implementing an engine change.

Move from IQ Bot Extraction package to Document Automation

As of the Automation 360 v.26 release, the IQ Bot Extraction package will be deprecated. Instead, configure your learning instances from Automation 360 IQ Bot to extract data in the new document processing solution, Document Automation.

Check if any bots in use the IQ Bot Extraction package: Navigate to **Manage > Packages**, and search for the IQ Bot Extraction package. If the status is **Enabled**, you must do steps on this page to identify the bots that contain the Process documents action and the associated learning instances, and configure those learning instances to run in Document Automation.

Packages

 Download free bots and packages from [Bot Store](#) 

Status	Name ↑	Vendor	Version	Bo
Enabled	IQ Bot Extraction	Automation Anywhere	1.0.0-20220307-024320	21

Set up your [Set up your Document Automation environment](#) on page 3466, which includes creating a custom role and users to perform tasks in Document Automation.

In this page, you connect your learning instances from Automation 360 IQ Bot, build a bot to upload documents to Document Automation, publish the learning instance assets, and deploy them to a Bot Runner.

1. Identify the learning instances that you must connect to Document Automation:
 - a) Navigate to **Automation** page, under the **Public** tab, locate the **Bots** folder.
 - b) Click on a Task Bot to open the Bot editor.
 - c) If the Task Bot contains the **IQ Bot Extraction > Process documents** action, locate the **Learning instance name** field and note the value. This is the name of the learning instance that you must connect to Document Automation.
 - d) Repeat these steps to identify all the learning instances that must be connected to Document Automation.

Connect your learning instances to Document Automation

When you connect a learning instance that was created in Automation 360 IQ Bot, the system creates learning instance assets (RPA bots, Automation Co-Pilot process, and form) to enable the learning instance to start processing documents in Document Automation.

Note:

- This feature is accessible only within Document Automation (not available in Community Edition). If you are an IQ Bot customer, you can use this feature within Document Automation.
 - The Automation 360 IQ Bot environment must be associated with the Control Room where Document Automation is installed. In addition, Automation 360 IQ Bot must be in a version that is compatible with the Control Room.
 - You can connect one learning instance at a time.
-

2. Login to the Control Room as the Admin user. Navigate to **Manage > Learning Instances**. Click **Connect learning instance**. This takes you to **Connect Learning Instances from IQ Bot classic page** which contains a list of Automation 360 IQ Bot learning instances.

3. Select the learning instance from version Automation 360 IQ Bot to connect with. Move it from left to right. Click **Connect**.

Connect Learning Instances from IQ Bot classic

You can edit the Learning Instance only in IQ Bot

<input type="radio"/>	S_MS	Purchase Orders
<input type="radio"/>	Z_T1	Purchase Orders
<input type="radio"/>	INT1	Invoices

→

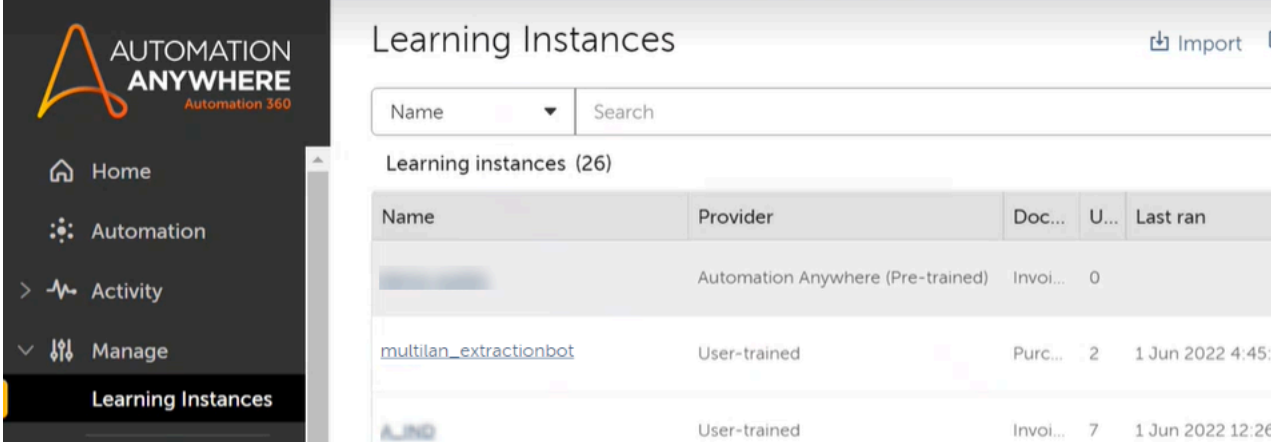

←

Selected (0)

	Name

The newly-connected learning instance appears in the Learning instances table in private mode.

4. Upload documents to the learning instance that you connected in the previous step to test its extraction capability.
 - a) Click **Process documents**.

The screenshot shows the Automation Anywhere interface. On the left is a dark sidebar with the logo 'AUTOMATION ANYWHERE Automation 360' and navigation options: Home, Automation, Activity, Manage, and Learning Instances (highlighted). The main area is titled 'Learning Instances' and features a search bar and a table with 26 instances. The table has columns for Name, Provider, Doc..., U..., and Last ran. Visible rows include 'Automation Anywhere (Pre-trained)', 'multilan_extractionbot', and 'A.LND'.

Name	Provider	Doc...	U...	Last ran
	Automation Anywhere (Pre-trained)	Invoi...	0	
multilan_extractionbot	User-trained	Purc...	2	1 Jun 2022 4:45
A.LND	User-trained	Invoi...	7	1 Jun 2022 12:26

- b)** In the **Process Documents** window, click **Browse** to select the files to upload.
- c)** In the **Download data to** field, enter the file path that will hold extracted data. When the process runs, it creates the following three folders in the provided file path:
- **Success**: Contains the extracted data in the specified format (CSV or JSON).
 - **Invalid**: Holds documents marked invalid.
 - **Failed**: Holds documents that could not be processed.

You can provide an output folder path based on one of the following options:

- **Option 1**: The local device path if you have set up document processing and validation on the same device.
This option is typically used when you are testing the learning instance.
- **Option 2**: The shared folder path if you have set up distributed validation on separate devices.
This option is typically used for published learning instances. For example, `\10.239.192.60\Sharepath\Output`.

- d)** Click **Process documents**.
The Bot Runner window appears. The window disappears when the documents are done processing. Refresh the **Learning instances** table to see the updated metrics.

If there is a value next to the **Validate documents** link, you must manually validate the document fields. Otherwise, proceed to step 3.

5. Fix the validation errors

- a)** Click **Validate documents**.
The Automation Co-Pilot Task Manager opens in a new tab, with the first failed document in queue. For an introduction to the Validator user interface, see [Using the Automation Co-Pilot Task Manager Validator for Document Automation](#) on page 3511.
- b)** Review each field to verify the data type and extracted value.
Document Automation supports the following data types: text, number, date, address, and check box
Alternatively, from the drop-down list on the right panel, you can select **Show fields that need validation**.

Note: When documents are awaiting validation, if you edit the learning instance, click **Reprocess** to reattempt extraction.

Reprocessing documents does not affect the uploaded documents metric.

c) Update the fields with errors.

Click the field or draw a box around the values that you want to extract.

For Automation Anywhere pre-trained models, you can configure the learning instance to extract specific values in a field and ignore others. For more information, see [Using validation feedback to extract specific values in a table](#) on page 3478.

- To skip a document without correcting errors, click **Skip** to proceed to the next document in the validation queue.
- To remove a document that cannot be processed, click **Mark as Invalid**.

d) After you make the necessary corrections, click **Submit** so that the document can finish processing.

The next document in queue appears. When all the documents are corrected, the system displays a message stating that no more tasks are available.

e) Close the tab to return to the **Learning Instances** page.

6. Verify the output results:

a) Open the file in the **Success** folder that contains the extracted data and review the results to ensure that it matches your use case.

b) Optional: Review the **Learning Instance** dashboard.

The dashboard displays the total number of uploaded documents and the number of documents pending validation.

Configure the learning instance to process documents in production

7. Build the `Extraction-Scheduler` bot to automate uploading documents to the learning instance: [Build a bot to upload documents to Document Automation](#) on page 3504

8. Publish the process.

a) Navigate to **Automation > Private tab > Bots > Document Workspace processes** and select the folder with the same name as the learning instance.

b) Mouse over the vertical ellipses to the right of the process to open the actions menu and click **Check in process**.

The **Check in Process** window opens with the bots and form auto-selected to also be checked in.

c) In the **Check in Process** window, add your comment and click **Check in**.

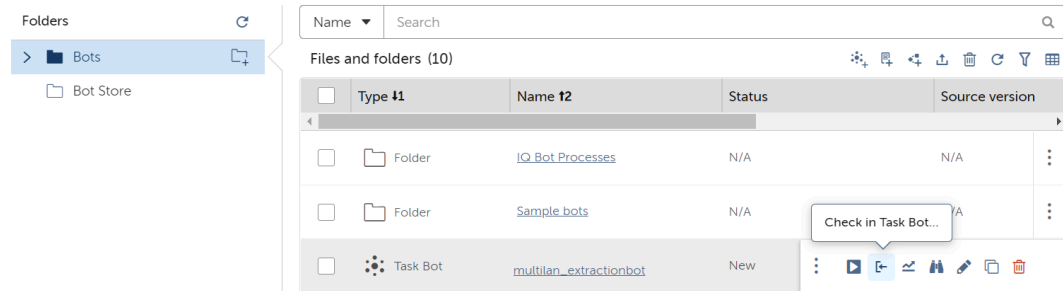

The process appears in the same folder structure in the public workspace.

See these steps in a video:

Note: The **Private** mode is used for testing in a controlled environment and cannot be viewed by other users. The **Public** mode is used when the bot is production-ready, allowing it to be viewed and accessed by others based on permissions set by the administrator.

9. Publish the **Extraction-Scheduler** bot.
 - a) Locate the **Extraction-Scheduler** bot in the private tab.
 - b) Mouse over the triple ellipses to the right of the bot to open the menu and click **Check in Task**

Private bots and files cannot be viewed by other people. If a bot or file has been checked out from the Public tab, it can be viewed and run by other people, but cannot be edited.

bot.

The **Check in Task bot** page opens with the bot auto-selected.

- c) Add a comment and click **Check in**.
10. Login as the **Document Automation Admin** user to deploy the process and bots to unattended Bot Runner devices: [Deploy the learning instance assets](#) on page 3510

Build a bot to upload documents to a specific learning instance for processing and extraction: [Build a bot to upload documents to Document Automation](#) on page 3504

Using IQ Bot Process documents action

Use this action to extract values from invoices using a pretrained model.

1. Drag the **Process documents** action into the workflow.
2. Use the **Learning instance name** drop-down menu to select an existing learning instance.
3. Select one of the following tabs for the input documents:
 - **Desktop folder:** Enter the folder path or click **Browse** to choose a folder.
 - **Variable:** Enter a variable name or browse to select a variable from the list.
4. Select the folder (instead of a single document) that has all the documents that must be processed.
5. Select the output folder from the **Output folder path** field.
6. Optional: Select the **Send documents to IQ Bot Validator for validation** check box.

Although the documents are processed using Bot Runners on your local machine, you must use this option if you want to validate the documents in the IQ Bot Validator.
7. Optional: In the **Group Label** field, provide the string variable that holds the name of the folder containing the sorted documents.

This is necessary for defining a user-created document group. For more information, see [Create a new document group](#) on page 3553.
8. Click **Save**.

After the Task Bot is run, the output folder can have up to four subfolders:

- **Success:** Contains documents that the package successfully extracted all the fields from and appear as .csv files.
- **Validate:** Contains documents that require validation.

The documents appear as .csv files and IQ Bot extracts the data before you validated it. However, if you select this option, these documents will be available in the Validator and you can download the validated output separately.

- **Retrain:** Contains documents that were sent for validation.

These documents are stored in their original input format and you can train them by uploading them to your existing learning instance. The package does not create new groups. To create new groups and train the failed documents, use the **Upload** option to send the documents from the `Output\Retrain` folder to your learning instance. The groups are created based on the **Groups Creation Threshold** defined in the learning instance.

- **Unprocessed:** Contains documents that were not processed due to runtime errors.

These documents are stored in their original input format and you can process them using the IQ Bot Extraction package.

If you use the IQ Bot Validator, the validated files are stored on the IQ Bot server output folder. Use the **IQ Bot > Download all documents IQ Bot: Download all documents** action to download files to your output folder on the local device.

IQ Bot package

The IQ Bot package enables you to upload and download documents from an IQ Bot server.

Actions in the IQ Bot package

The IQ Bot package includes the following actions:

Action	Description
Download all documents	See Download all documents action on page 2653.
Upload document	See Upload document action on page 2654.

To perform these tasks using APIs, see [APIs to upload files, check file status, and downloading CSV file \(A-People login required\)](#)

Download all documents action

Use the **Download all documents** action to download the extracted results from an IQ Bot server that were created by running a Bot with the **Upload Document** action.

Note: To perform this task using an API, see [using APIs to upload files, check file status, and download CSV files \(A-People login required\)](#).

IQ Bot extracts fields from documents and exports them as CSV files. This action can also download any unclassified, untrained, and invalid documents to your local directory.

Follow these steps to download extracted results from the IQ Bot server:

1. In the **Actions** palette, double-click or drag the **Download all documents** action from the **IQ Bot** package.
2. In the **Learning instance name** field, select the name.
3. In the **Document status**, select the appropriate status for the documents.
 - **Success**: Documents have been processed and are in `.csv` format.
 - **Invalid**: Documents were marked as invalid during the validation process.
 - **Unclassified**: Documents could not be classified into any groups.
 - **Untrained**: Documents were classified into new groups during processing and require training.
 - **Fail**: Documents that failed to process and require re-processing. A document reflects **Document status** as **Fail** if an exception occurs during data extraction, validation, or storing of the final output to the database.

Unprocessed documents in **Invalid**, **Unclassified**, **Untrained** and **Fail** folders are available in their original format. For example, if your input documents were in a `.pdf` format, the output in the above folders are obtained in the `.pdf` format as well.

Note: After you upload a document by using the **Upload** action, to retrieve the latest results from the server, you need to run the **Download** action periodically. Ensure to maintain a delay of 30 seconds to 1 minute between the execution of two consecutive IQ Bot **Download** action of the same nature.

4. In the **Local output folder** field, provide the path to the file that will hold the output.
5. In the **Delete files from the server after downloading** check box, select the option to delete documents.

When you choose this option, even if your download fails, a compressed `.zip` file containing the failed documents is available for downloading again. Therefore, you must select this option.
6. Optional: In the **Save the response to a variable** field, add a variable. For example, select **prompt-assignment - string** from the drop-down list.

A variable value in this field provides information on whether the download was successful or failed, and the reason for the failure.
7. Click **Update**.
8. Click **Save**.
9. Click **Run now**.
10. Click **Close**.

Note: If the download fails, verify the variable value using a **Message Box** or **Log to File** action. See the **Save the response to a variable** description.

11. Navigate to the local output folder to review the downloaded files.

Upload document action

The **Upload Document** action enables you to upload a document with IQ Bot. IQ Bot extracts fields from the document and exports them to CSV files.

- Gain access to an Control Room.
- Ensure your local host is a registered device in the Control Room.

Note: To perform these tasks using APIs, see [using APIs to upload files, check file status, and download CSV files \(A-People login required\)](#).

Use the **Upload Document** action to upload a single document to the Control Room.

Note: Azure confidential computing enables organizations to upload encrypted data to secured storage, such as private folders on a virtual machine. If you upload documents from such secured folders to IQ Bot, these are moved to **Unclassified** status as data extraction is not supported for such documents.

Follow these steps to upload a document:

1. In the **Actions** palette, double-click or drag the **Upload Document** action from the **IQ Bot** package.
-

Note: A file size of 50 MB is supported for the upload action.

Note: The file names of the documents that you upload should not start with special characters, such as the hyphen (-).

2. In the **Learning instance name** field, select the name.
3. In the **File path** field, specify the location or type of the file.
4. Optional: In the **Group Label** field, provide the string variable that holds the name of the folder containing the sorted documents.
This is necessary for defining a user-created document group. .
5. Optional: In the **Save the response to variable** field, add a variable. For example: select **prompt-assignment - string** from the drop-down list.
A variable value in this field provides information about the file upload process: if the upload was successful or failed, and the reason for the failure.
6. Click **Apply**.
7. Click **Save**.
8. Click **Run now**.
9. Click **Close**.

To upload multiple files, insert the **Upload Document** action into a **Loop** action. See the [Loop package](#) on page 2679.

JavaScript package

The **JavaScript** package contains actions to run a JavaScript from a bot. These actions can run JavaScript on Windows, Linux, and UNIX based devices.

Before you start

1. Open a JavaScript file, or specify the script you want to run using the **Open** action. You must associate the details of the file or script you want to run with a session name. Use this same session name for other **JavaScript** actions.

2. Use the **Run JavaScript** action to run a function within a script or an entire script. You must use the same JavaScript session name established in the **Open** action.
3. Close the JavaScript session after running the script.

To review the bot launcher logs, navigate to `C:\ProgramData\AutomationAnywhere\BotRunner\Logs\<current month>\Bot_Launcher-<today's date>.log.zip`. Each zipped folder contains a file with data on the code execution, which is useful for debugging.

Note: Review the following known JavaScript exceptions (other exceptions might exist based on individual scenarios):

- All JavaScript run with JavaScript actions on the terminal.
 - We do not support any JavaScript that requires a browser to run.
-

Actions in the JavaScript package

The JavaScript package includes the following actions:

Note: If you built a bot using actions from the JavaScript package from Build 5322 or earlier, the actions will be missing when you open the bot with the default package version. You must reinsert the actions and repopulate the fields.

Action	Description
Close	See Close action in JavaScript on page 2656.
Open	See Open action in JavaScript on page 2657.
Run JavaScript	See Run JavaScript action on page 2657.

Related reference

[JavaScript package updates](#) on page 862

Review the updates in released versions of the JavaScript package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Close action in JavaScript

This action enables you to close the session.

Settings

To close the JavaScript, specify the same session name from the **Open** action.

Open action in JavaScript

You can open a JavaScript file using this action.

Settings

Opens a JavaScript file.

- In the JavaScript **session** field, specify a session name. Use this same session name for other JavaScript actions.
- Choose one of the following options:
 - In the **Import existing file** option, select an existing JavaScript file.

Note: If you are uploading a script from a file on your desktop, the file and any dependencies must be in a standalone folder. When you select a file for upload, all files and folders at the same folder level are uploaded.

- In the **Manual input** option, enter the JavaScript.

Run JavaScript action

This action enables you to run a function within the JavaScript file.

Settings

Runs a function within the JavaScript.

- In the JavaScript **session** field, specify a session name. Use the same session name from the **Open** action.
- Optional: Specify the function name to run and the arguments to pass to the function.

Note: You can pass only a list variable as an argument for the function. You can use the list variable to pass multiple arguments of different data types such as Boolean, datetime, number, and string.

- Optional: In the **Assign the output to variable** field, specify the variable. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Json package

Extract the required information from Json text or file by using the Json package and use the extracted values in your bots.

Before you start

Use the actions in the Json package in the following order:

1. Start the Json session using the **Start session** action. Use this session name for all corresponding actions.
2. Use the different actions available in the Json package to automate Json-related tasks.
3. End the session using the **End session** action to complete a task.

Actions in the Json package

The Json package includes the following actions:

Action	Description
End session	See End session action in JSON on page 2658.
Get node list	See Get node list action in JSON on page 2658.
Get node value	See Get node value action in JSON on page 2659.
Start session	See Start session action in JSON on page 2660.

End session action in JSON

You can close a JSON session using the **End session** action.

Settings

Closes a Json session.

- Enter the session name or select a variable used in the **Start session** action.
- Save and close the session.

Get node list action in JSON

This action enables you to retrieve a list of nodes for a node path.

Settings

Retrieves the list of child nodes for a node path.

Note: When you run the **Json > Get node list** action to retrieve numbers, and if a number contains a decimal point and has more than seven digits, the number retrieved is converted to scientific notation (exponential number) and does not display correctly. For example, the number 77777778.07 is retrieved as 7.7777778E7.

Workaround: To retrieve a correctly formatted number, perform the following steps-

1. In the bot, use the **String to locale number** action to convert a string to a locale-formatted number.
2. Use the **Number to string** action with decimal point accuracy to convert a user-specified number to a string.

- Enter the key or node path to retrieve multiple nodes or select a variable.
- Enter the session name or select an existing variable used in the **Start session** action.
- In the **Save the outcome to variable** field, select a list type variable to hold the output.

For more information on how to use some of the actions (including Get node list), see this example topic [Example of using JSON package actions in a bot](#) on page 3124

Get node value action in JSON

You can retrieve the node value in JSON.

Settings

Retrieves the value of a node.

- Enter the key or node path to retrieve multiple nodes or select an existing variable.

You can select a single record from an array of records and pass an index number to select the specific record from an array. For example,

```
{
  "CompanyName": "XYZ Inc.",
  "CompanyAddress": "NY, USA",
  "CompanyPhone": "9876543210",
  "CompanyEmployees": [
    {
      "id": 1,
      "first_name": "Hilly",
      "last_name": "Triplet",
      "email": "htripler0@earthlink.net",
      "gender": "Male",
      "ip_address": "152.189.110.100"
    },
    {
      "id": 2,
      "first_name": "Nathaniel",
      "last_name": "Pagitt",
      "email": "npagitt1@google.de",
      "gender": "Male",
      "ip_address": "54.93.141.163"
    },
    {
      "id": 3,
      "first_name": "Lauree",
      "last_name": "Gendrich",
      "email": "lgendrich2@nba.com",
      "gender": "Female",
      "ip_address": "117.24.49.36"
    }
  ],
}
```

```
{
  "id": 4,
  "first_name": "Ike",
  "last_name": "Caines",
  "email": "icaines3@adobe.com",
  "gender": "Male",
  "ip_address": "166.174.181.87"
}
]
```

When you enter the node path `CompanyEmployees[2].first_name`, the output is retrieved as Lauree, and if you enter the node key `CompanyAddress`, the output is retrieved as NY, USA.

- Enter the session name or select a variable used in the **Start session** action.
- In the **Save the outcome to variable** field, select a string type variable to hold the output.

Start session action in JSON

This action enables you to create a new JSON session based on a JSON file or specified text.

Settings

Creates a new JSON session based on a JSON file or specified text.

- Start the JSON session.
- In the **Data Source** field, select either **File** or **Text**:
 - File: Select from the **Control Room file**, **Desktop file**, or an existing **Variable** of File type.
 - Text: Specify the text name or select a variable.

Note: `.json` and `.txt` extensions are supported in the file path for the **Desktop** option.

- Select any of the following tabs from the JSON object session to create a JSON session:
 - **Local session:** Specify a session name that can be used only in the current bot.
 - **Global session:** Specify a session name that can be used across multiple bots, such as parent bots, child bots, and other child bots of the parent bots.
 - **Variable:** Specify a session variable that can be used to share that session with other child bots.

Legacy Automation package

The actions in the Legacy Automation package are only used in migrated bots to ensure that they run seamlessly in Automation 360. We do not recommend using this package for new bot development.

Note: If you built a bot using actions from the Legacy Automation package from Build 5322 or earlier, the actions will be missing when you open the bot with the default package version. You must reinsert the actions and repopulate the fields.

Expressions

Expressions appear in action input fields. This package has the following expressions:

Expression	Description	Use example
DictionaryToString	Converts a dictionary variable to a string variable	<pre>{{DictionaryVar.LegacyAutomation:dictionary}}</pre> <p>The output is a string variable with the following value: {key1,value1}, {key2,value2}</p>
GetAbsolutePath	<p>Provides you the relative path of all (non-Automation Anywhere) files present on your system by having a global variable at the start of the path. In Enterprise 11 or Enterprise 10, the equivalent of GetAbsolutePath is present at Tools > Options > Runtime Settings > Start in path of task.</p> <p>In Enterprise 11 or Enterprise 10, any folder in the repository can be used as a starting path for the GetAbsolutePath value. If the path in the Enterprise 11 or Enterprise 10 bot is an absolute path, the migration process does not make any change to the migrated bot. If the path in the Enterprise 11 or Enterprise 10 bot is a relative path and contains a variable, the migration process adds a global variable at the start of the path as prefix alongside the relative value path.</p>	<ul style="list-style-type: none"> • <code>variable.txt</code>: The input provided in this example is a relative path, and the output will be <code>C:\testing\variable.txt</code>, where, <code>C:\testing\variable.txt</code> is a start-in path. • <code>\\datashare\variable.txt</code>: The input provided in this example is a network path, and the output will be <code>\\datashare\variable.txt</code>. • <code>D:\testing\Automation Anywhere Files\Automation Anywhere\My Docs\mydoc.docx</code>: The input provided in this example is an absolute path, and the output will be <code>D:\testing\Automation Anywhere Files\Automation Anywhere\My Docs\mydoc.docx</code>.

Expression	Description	Use example
GetBotPath	Modifies the value of the bot path variable in the Enterprise 11 or Enterprise 10 bots and replaces it with the relative bot path according to the Automation 360 repository. The value of the bot path is based on the <code>ApplicationPath</code> of the local path or network path.	<ul style="list-style-type: none"> D:\testing\Automation Anywhere Files\Automation Anywhere\Bots\My Tasks \test.atmx: The input provided in this example is an absolute path, and in this case, the output path will be <code>My Tasks/test</code>. <code>\$\$\$ApplicationPath\$ \Automation Anywhere Files \Automation Anywhere\Bots\My Tasks\test.atmx</code>: The example provided in this input is related to <code>\$\$\$ApplicationPath \$</code>, and the output will be <code>My Tasks/test</code>. <code>\\Automation Anywhere Files \Automation Anywhere\Bots \My Tasks\test.atmx</code>: The example provided in this input is a network path, and the output will be <code>My Tasks/test</code>.
GetDecrementedListIndex	Decrements the value of the respective variable by 1. It is used mostly in the index positions of list, record, array or table variables.	<code>myArray[\$Loop-Counter-1.LegacyAutomation:getDecrementedListIndex]</code> The output of <code>myNumber</code> decreases by 1 with each iteration of the loop.
GetIncrementedListIndex	Increments the value of the respective variable by 1. It is used mostly in the index positions of list, record, array or table variables.	<code>myArray[\$Loop-Counter-1.LegacyAutomation:getIncrementedListIndex]</code> The output of <code>myNumber</code> increases by 1 with each iteration of the loop.
GetKeystrokeCount	Calculates the values of keystrokes in a phrase/text Note: A special character, such as [TAB], [END], or [PAGE DOWN], is counted as one keystroke.	<code>myPhrase.LegacyAutomation:getKeystrokeCount</code> The output is the average delay for each keystroke.

Expression	Description	Use example
GetLegacyIndex	Retrieves the value from the specific index position of the list variable in the bots migrated from Enterprise 11 or Enterprise 10. If the index position is greater than the size of the list variable, the system retrieves the value from the first index position of the list in the migrated bots	
ListToString	Converts a list variable to a string variable.	<pre>{{ \$listVar.LegacyAutomation:listToString \$ }}</pre> <p>The output is a string variable with the following value: value1,value2,value3</p>
ListToTable	Converts a list variable to a table variable.	<pre>{{ \$my-list-variable.LegacyAutomation:listToTable \$ }}</pre> <p>The output is a table variable where each list value is cell in a single column.</p>
ParseLegacyKeys	<p>Ensures that the Insert Key Stroke command of the Enterprise 10/Enterprise 11 bots stored in variables is successful upon execution. This expression converts them into equivalent Automation 360 key strokes during the execution.</p> <hr/> <p>Note: The appearance of some special characters differs between Version 11.3 and Automation 360. For example, the Page Up key appears as [PAGE UP] in Version 11.3 and [PAGE-UP] in Automation 360. This difference does not impact bot function.</p> <hr/>	<pre>\$Test.LegacyAutomation:parseLegacyKeys \$</pre>
ParseVariable	<p>Parses the expression provided in the Enterprise 10/Enterprise 11 Variable Operation command. This expression ensures that Automation 360 returns the same output as Enterprise 10/Enterprise 11 bots upon execution.</p>	<pre>\$prompt-assignment.LegacyAutomation:parseVariable \$</pre>

Expression	Description	Use example
TableToString	<p>Converts a table variable to a string variable.</p> <p>You can also use delimiters such as a colon, semicolon, or space to separate the values of the string variable in the output.</p>	<pre>{{ \$tableVar.LegacyAutomation:tableToString }} \$ }</pre> <p>The output is a string variable with the following value: {value1,value2}, {value3,value4}</p> <p>Use a colon, semicolon, or space as <"delimiter">: {{ \$tableVar.LegacyAutomation:tableToString }} For example: {{ \$tableVar.LegacyAutomation:tableToString }} \$ } <p>The output is a string variable with the following value: {value1:value2}: {value3:value4}</p> </p>
TableToList	<p>Converts a table variable to a list variable.</p>	<pre>{{ \$DataTable.LegacyAutomation:tableToList }} For example: {{ \$DataTable.LegacyAutomation:tableToList }} \$ }</pre> <p>The output is a list variable with the following value: [value1,value2,value3]</p>
StringToList	<p>Converts a string type variable to a list type variable</p>	<pre>\$SampleString.LegacyAutomation:stringToList \$ }</pre> <p>The output is a list variable of size 1 with value same as "SampleString"</p>
StringToTable	<p>Converts a string type variable to a data table type variable</p>	<pre>\$SampleString.LegacyAutomation:stringToTable \$ }</pre> <p>The output is a data table variable with size (1*1) and value at index [0,0] same as SampleString</p>

Review the updates in released versions of packages such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using legacy Web actions

In Automation 360, all the commands (except Find broken links and Download files) of Web recorder are migrated to their respective actions within the Legacy Automation package. We do not recommend using the Legacy Automation package for new bot development.

Web actions in the Legacy Automation package

The Legacy Automation package includes the following actions:

Action	Description
Close page	Closes the browser session for an opened browser window or tab.
Update window title	<p>Updates the window title during migration of bots, from Internet Explorer to Microsoft Edge with IE mode. On execution of this action, the window title is changed to *Microsoft*Edge format. This action is used only when the window title is determined by a variable and not when the window title is static. The window title is updated when the bot is run and not during the conversion process.</p> <ul style="list-style-type: none"> In the Window field, select an option: Choose the Application, Browser, or Variable tab. <ul style="list-style-type: none"> Application: Select from a list of windows, including browser windows, that are currently open on the Bot Creator device. Browser: Select from a list of supported browser tabs. Variable: Select an existing window variable to specify the title of the application window title. <hr/> <p>Note: Although the property panel contains the Browser and Application options, only the Variable option is used during migration.</p> <hr/> <ul style="list-style-type: none"> Select an option to specify whether the window title is a regular expression or not. When this action is executed, the New window title field displays the changed window title (Microsoft Edge with IE mode).

Action	Description
Execute java script function	<p>Executes JavaScript internally on a web page in Internet Explorer or Microsoft Edge (IE mode).</p> <p>You can run JavaScript inside a web page by providing JavaScript as an action input. When you run a JavaScript function, you can see and edit the properties of the selected iFrame.</p> <ul style="list-style-type: none">• Specify the URL.• Specify the function name to run and the arguments to pass to the function.• Specify the variable in Assign the output to variable field (optional).
Extract data	<p>Extracts data from a specified URL in Internet Explorer or Microsoft Edge (IE mode).</p> <ul style="list-style-type: none">• Specify the website URL to extract data from a web page.• Enter the control type and control value.• If you want to reuse an existing tab or window, mark the check boxes and specify the Page Title or Page URL properties to the action.• Specify the time in seconds in Wait for the control to exist. The default time is 30 seconds.• In the Save outcome to a variable field, select either Multiple variables or Dictionary:<ul style="list-style-type: none">• Multiple variables: Click Add variable mapping to associate each dictionary key with a variable in the parent bot. Use this option if you do not want to use actions to extract the dictionary values.• Dictionary: Insert or create a dictionary variable to hold the output variables and values in key-value pairs.

Action	Description
Extract pattern data	<p>Extracts pattern-based data from an Internet Explorer page. Use pattern-based data extraction when the web entries follow a pattern. This feature recognizes the pattern and extracts the data even if it spans several pages. The extracted data is saved to a CSV file.</p> <ul style="list-style-type: none">• To extract pattern-based data, enter the website URL and page title. You can preview the extracted captured data and its value.• Specify the location of the CSV file in which you want to write the data.• Select an option to specify what to do when writing data to a file:<ul style="list-style-type: none">• Append to the file• Override the file• Select an option from the encoding list to specify the encoding that you want to apply on the file. The default encoding is set to ANSI.<ul style="list-style-type: none">• ANSI• UTF-8• Unicode
Extract source	Extracts the source of an element on a specified webpage and assigns the value to a variable.

Action	Description
Extract table	<p>Extracts the table from a specified URL and optionally saves to a new CSV file or appends to an existing CSV file.</p> <ul style="list-style-type: none"> Specify the URL to open a web page in an Internet Explorer window. Specify the table number to extract the table data. Specify the location of the CSV file in which you want to write the data. Select the Append to an already existing csv file check box when writing data to an existing file. Select an option from the encoding list to specify the encoding that you want to apply on the file. The default encoding is set to ANSI. <ul style="list-style-type: none"> ANSI UTF-8 Unicode Specify the time in seconds in Wait for the control to exist. The default time is 30 seconds. Enter the session name in the session name field. If you want to reuse an existing tab or window, mark the check boxes and specify the Page Title or Page URL properties to the action. Provide the tag details (Tag name and Attribute name) of the extracted table data and save the result in a CSV file or assign the output to a data table variable.
Go back	Navigates to the previous page.
Manage web controls	<p>Identifies the properties of a UI control from a specified website.</p> <ul style="list-style-type: none"> Select the option to open a new URL or Select page. You can provide the search criteria of the captured object. Search the object by specifying Control name, Value or Index. If you want to reuse an existing tab or window, mark the check boxes and specify the Page Title or Page URL properties to the action. Select the control type from the drop-down menu. Specify the time in seconds in Wait for the control to exist. The default time is 30 seconds. Choose a variable to assign an output to a variable.
Navigate to page	<p>Opens a web page in an existing Internet Explorer window.</p> <ul style="list-style-type: none"> Specify the URL in the Navigate URL field to open a new window with a specified URL. If you want to overwrite an existing tab or window, mark the check boxes and specify the Page Title or Page URL properties to the action.

Action	Description
Open page	<p>Opens a web page in Internet Explorer to a specified URL.</p> <ul style="list-style-type: none"> Specify the URL to open a web page in an Internet Explorer window. If you want to reuse an existing tab or window, mark the check boxes and specify the Page Title or Page URL properties to the action.
Search by caption	<p>Searches the first opened Internet Explorer window for the specified caption and occurrence frequency. You can update the Caption and Occurrence in the bot.</p>
Configure settings	<p>Set the configuration option for the web actions. You can select one of the following options or all:</p> <p>When you configure this action with the following settings, the settings configured will apply to all the actions under the Web group.</p> <ul style="list-style-type: none"> Launch Internet Explorer as a process. Open a browser in the background. Launch Internet Explorer in Edge compatibility mode. <hr/> <p>Note: When you select the Launch Internet Explorer in Edge compatibility mode check box, all the automation you previously built on Internet Explorer 11 using Web actions will run and work in Microsoft Edge with IE mode. The actions within the Web group run seamlessly in Microsoft Edge with IE mode.</p> <hr/>

List package

The **List** package contains actions that enable you to perform various operations on a variable of the list data type.

Working with variables of list data type

A list is a collection of ordered values. The values can be of Boolean, number, or string data subtype. When initializing a list variable, you can select the **Any** data subtype in order to hold any of the three data subtypes. You can manually enter values by creating a new variable or selecting an existing one from the **Variables** menu, and then clicking **Add**.

Common uses of list variables include:

- Sending an email to multiple recipients.
- Searching multiple web addresses.

Note:

- Sorting of list values is currently not supported.
- You cannot directly assign values from the record to a list. However, you can use **Loop** action to loop through all the record items and then add them to the list variable.

Actions in the List package

If you are using a **List** action in a **Loop** action, you must use the **For each item in the list** iterator.

The following actions are available in the **List** package:

Action	Description
Add item	See Add item action in List on page 2672.
Append	See Append action in List on page 2672.
Assign	See Assign action in List on page 2673.
Clear	See Clear action in List on page 2673.
Get item	See Get item action in List on page 2673.
Join items	See Join items action in List on page 2675.
Remove item	See Remove item action in List on page 2676.
Set item	See Set item action in List on page 2676.
Size	See Size action in List on page 2676.

Example

Create a bot to add items to a list and retrieve data from a list. To achieve this functionality, perform the following steps:

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name: `ListBot`
 - d) Click **Create and Edit**.
2. Create the following variables.
 - Variable: `StringList`
 - **Type**: `List`
 - **Subtype**: `String`
 - **Name**: `StringList`
 - **Default value at 0**: `Automation`

- **Default value at 1:** Anywhere
 - Variable: SampleString
 - **Name:** SampleString
 - **Default value:** PvtLtd
 - Variable: ListOutput
 - **Type:** Any
 - **Name :** ListOutput
3. To insert an item into a list variable, from the Actions pane, double-click or drag the **List > Add item** action.
 - a) In the **List variable** field, select `StringList`.
 - b) In the **Items to be added** field, select `SampleString`.
 - c) To insert the item at the end of the list, select the **To end of list** option.
 4. To retrieve a value at a specified position in a list, from the Actions pane, double-click or drag the **List > Get item** action.
 - a) In the **List variable** field, select `StringList`.
 - b) In the **Index number** field, enter 0. This is to specify the position in the list from where you want to retrieve a value.
 - c) To store the output from **Assign the output to variable list**, select `ListOutput`.
 5. To print the value of the Index 0, double-click or drag the **Message box** action. Click **Save** and **Run**.

The bot displays the zero index data of the list variable, which is **Automation**.

Related reference

[Loop package](#) on page 2679

Use the Loop package to run a sequence of actions repeatedly for a specific number of times or until a specific condition is met.

[Variables overview](#) on page 2235

Automation 360 offers a variety of variables, each designed to hold specific types of data and is intended for specific use. Use the topics below to learn more about each variable and how to use them.

[List package updates](#) on page 865

Review the updates in released versions of the List package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Add item action in List

The **Add item** action enables you to insert an item into a list variable.

Settings

You can choose to add the item at the end of the list or specify a position in the list.

- Select the list variable in which to add an item from the **List variable** list.
- Select the variable that contains the value to add from the **Item to be added** list.

Note: The variable must be of the same sub-data type as the other list items.

- Select the **To end of list** option to insert the item at the end of the list or select **At list index** to specify the index in the list where to insert the item.

The list index starts from 0. The first item in the list is at position 0, the second item at 1, and so on. For example, to add an item at the fourth position in a list, enter 3 in the **At list index** field.

Append action in List

The **Append** action enables you to add a list variable into the column index of a data table.

Settings

You can choose to add the list variable at the start or end, or specify a position in the data table.

- Select the list variable that contains the value to be added.
- In the **Assign the outcome to Data Table** field, select a table variable that you want to use to store the output.
- Choose from the following options to insert a column at index:
 - **First index:** Sets the value to the first position (0 index) in a data table.
 - **Last index:** Sets the value at the end of the data table.
 - **Specific index:** Specify the index where you want to enter the column index. For example, to set a value to the first column, enter 0.

The index number starts from 0. The first item in the data table is at position 0, the second item at 1, and so on. For example, to add an item at the third position in a data table, enter 2 in the **Specific index** field.

Assign action in List

The **Assign** action enables you to assign the value of the source list to the destination list variable.

Settings

- On the **List** tab, select the source list variable from the drop-down list and specify a value in the **Value at 0** field or create a new list variable.
- On the **Variable** tab, insert a value for the list variable.
- Select a destination list variable or create one to hold the output.

Clear action in List

Use the Clear action to clear all items from the selected list variable.

Settings

Select the list variable from which you want to clear the items.

Get item action in List

You can retrieve a value at the specified position in a list and store the output to a variable using the **Get item** action.

Settings

- Select the list variable from which you want to retrieve a value from the **List variable** list.
- Specify the position in the list from where you want to retrieve the value in the **Index number** field. The list index starts from 0. The first item in the list is at position 0, the second item at 1, and so on.
- Select a variable that you want to use to store the output from the **Assign the output to variable** list.

Example

For example, to create a bot to retrieve data from a list where you want to see data from sales of the iPhone14 on product launch day, perform the following steps:

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name: `List_Get_item`.

- d) Click **Create and Edit**.
2. Create the user-defined variables using the **Create variable (+)** icon at the top of the **Variables** menu.
- a) Create a variable of **List** type and select the **Any** data subtype to include any data subtypes (String, Boolean, Number, Datetime, or File).
- b) Select the type and enter the following values:

Type	Value
Datetime	6/15/2023
Number	100
String	Customer footfall
String	Apple Oakridge - San Jose store
String	Phone type - iPhone
String	iPhone 14 pro max
String	iPhones sold - 10 Qty
Boolean	true

3. To retrieve a value at a specified position in a list, from the **Actions** pane, double-click or drag the **List > Get item** action.
- a) In the **List variable** field, select `CustomerData`.
- b) In the **Index number** field, enter 1 to specify the position in the list from where you want to retrieve a value.
- c) To store the output from **Assign the output to variable list**, select `SampleNumber`.
4. To print the value of the Index 1, double-click or drag the **Message box** action. Enter the value `$CustomerData[1].Number:toString$` in the **Enter the message to display** field.
5. Click **Save** and then **Run**.
The bot displays the one position index data of the list variable (**100**).
6. Repeat Step 3.
7. Drag the **Datetime > To String** action.
- a) Select the **Variable** option from the **Source date and time variable** field.
- b) Select `SampleString` from **Assign the output to a variable** field.
8. To print the values, drag the **Message box**. Enter the following values in the **Enter the message to display** field:
- `$SampleString$`
 - `$CustomerData[1].Number:toString$`
 - `$CustomerData[2]$`
 - `$CustomerData[3]$`

- \$CustomerData[4]\$
- \$CustomerData[5]\$
- \$CustomerData[6]\$
- \$CustomerData[7].Boolean.toString\$

9. Click **Save** and then **Run**.

The output is displayed as:

The output shows that on June 15, 100 customers visited the Apple store in San Jose on the product launch day, and ten iPhones were sold. The `true` value indicates that iPhone is the best-selling smartphone of 2023.

Join items action in List

The **Join items** action enables you to combine all the available values in a list variable and store the output to a string variable.

Settings

Combines all the available values in a list variable and stores the output to a string variable. You can specify the delimiter you want to use as a separator in the output.

- Select the list variable that you want to use from the **List variable** list.
- Specify the delimiter you want to use to separate values in the output in the **Delimiter** field.
- Select a variable that you want to use to store the output from the **Assign the output to variable** list.

Remove item action in List

The **Remove item** action enables you to remove an item from a list and assign the output to a variable.

Settings

- Select the list variable from which you want to remove an item from the **List variable** list.
- Specify the position in the list from where you want to remove the value in the **Index number** field. The list index starts from 0. The first item in the list is at position 0, the second item at 1, and so on.
- Select a variable that you want to use to store the output from the **Assign the output to variable** list.

Set item action in List

You can set an item at the specific position in a list and store the output in a variable using the **Set item** action.

Settings

- Select the list variable in which you want to set a value from the **List variable** list.
- Specify the position in the list where you want to set the item in the **Index number** field. The list index starts from 0. The first item in the list is at position 0, the second item at 1, and so on.
- Select a variable from the drop-down list in the **Replace with** field to replace the list variable.
- Select a variable that you want to use to store the output from the **Assign the output to variable** list.

Size action in List

The **Size** action enables you to retrieve the number of items in a list and assign the output to a number variable.

Settings

- Select the list variable for which you want to retrieve the size from the **List variable** list.
- Select a number variable that you want to use to store the output from the **Assigns the number of items to variable** list.

Log To File package

Use the `Log To File` package to create a log file with data.

The `Log To File` package enables the following:

- Verify that a bot ran properly.

- Create a new log file.
- Specify custom text to be included in the log file.
- Add a time stamp to the log file.
- Use a log file as a variable.

Note: The package supports ANSI, Unicode, and UTF8. It can save files as .csv and .txt.

Actions in the Log To File package

The Log To File package includes the following action:

Action	Description
Log to file	See Using Log text to file action on page 2677.

Using Log text to file action

The **Log text to file** action in the Log To File package enables you to create a log file with data about the events that occur when a Task Bot runs.

Follow these steps to log text into a file:

1. In the **Actions** palette, double-click or drag the **Log to file** action from the Log To File package.
2. In the **File path** field, specify the file location or variable.
3. In the **Enter text to log** field, enter the text to log in the file.
4. Select the **Append timestamp** check box to add a time stamp.
5. In the **When logging** field, choose **Append to existing log file** to append the log file or **Overwrite existing log file** to overwrite the content in the log file.
6. Select the **Encoding** type.
 - **ANSI:** Used to encode Latin alphabet.
 - **UNICODE**
 - **UTF8:** Can encode all possible characters.
 - **UTF-16LE:** Inserts a byte order mark (BOM) Unicode character at the beginning of the file.

Note: Shift-JIS files must use **ANSI** as encoding to read text file content.

If you selected the **Append to existing log file** option in Step 5, ensure that the selected encoding type matches that of the original file, otherwise some of the characters might not be logged.

7. Click **Save**.

Log variables to file action

You can use the **Log variables to file** action in the Log To File package to log user-defined variables to a log file. When an automation (bot) fails, you can use this action to troubleshoot issues offline by reviewing the log file and value of the variables for correctness.

Procedure

1. In the **Output file path** field, browse and select the file path of the log file. If the specified log file does not exist, then a new log file is created at run time.

Note: We support .txt format for the log file.

2. In the **When logging** field, select one of the following options:
 - **Append to existing log file:** To append the content to an existing log file.
 - **Overwrite existing log file:** To overwrite the content in the log file.
3. **Append timestamp:** Select this check box to add a timestamp. If you select this option, the log file will display information about the logging timestamp (date and time). For example, if you change the value of the variables at different times, you can select this option to pinpoint the date and time of the changes, and the Task Bot name these changes occurred.
4. Select one of the following options from the **Variables to log** field:

Note: We support logging user-defined variables of String, Number, Boolean, and Datetime data types only.

- **By type:** You can use this option to log user-defined variables of basic data types based on type selection. You can log all String variables, all Number variables, all DateTime, and all Boolean variables simultaneously.

Note: When you select the **By type** option, you can also log variables that are created later after you have added the **Log variables to file** action.

- **Custom selection:** You can use this option to select and log individual variables of basic data types such as String, Number, DateTime, and Boolean.

Note: If you created any new variable after you added the **Log variables to file** action to the bot and enabled the **Select all variables** check box, the new variable is not auto-selected and will not be logged even if you selected the **Select all variables** option. The variable appears unchecked in the **Custom selection** list where you must select that variable explicitly.

The following video shows how to log user defined variables to a log file.

See on how to use the Log variables to file action [Example of using Custom selection option in Log variables to file action](#) on page 3138.

Loop package

Use the Loop package to run a sequence of actions repeatedly for a specific number of times or until a specific condition is met.

The Loop package enables you to repeatedly run specific actions within a bot. For example, repeat the set of actions that read data from each row of a Microsoft Excel file, rename all files in a folder, and save each email in a mailbox. You can also use the **If** action within the Loop action to validate a condition, and based on the outcome of it, skip the current iteration in the loop or even break the loop.

For conditional loops, different actions are taken depending on whether the conditional parameters are met. For loops that have a specified number of iterations, the loop exits on the last iteration and goes to the next step in the bot.

When you run a sequence of actions repeatedly for a specific number of times within a loop, the end condition within the loop is evaluated in every iteration.

For example, when you loop through a Data Table that has 10 columns, enter dynamic values of column count for the end condition in the loop, use the **Data Table > Delete column** action to delete the column of index 0 inside the loop body, and then run the bot, the bot deletes a column in every iteration. Hence it reduces the iteration count because the loop end condition is evaluated in each iteration.

Note: You can run the bots with a maximum number of 97 nested loops.

Loop labels

You can use the **Label** field in the actions of the Loop package to label the loops used in a bot. By labeling of loops, you can break or continue a specific loop from nested loops.

Note: To use this feature, ensure that you build your bots using Loop package version (3.7.4) to use this feature. This feature is not backward compatible.

To add labels to the **Loop**, **Continue**, or **Break** actions, in the **Label** field, specify a label for the loop.

Note:

- Ensure that each loop label in a specific bot is unique.
 - The **Label** field supports only alphanumeric characters.
-

The following example describes how to use the **Label** field to break or continue a loop in a bot:

- In the **Label** field of the first Loop action, specify a label as `outerloop`.
- In the **Label** field of the second Loop action, specify a label as `innerloop`.
- In the **Loop > Continue** action, in the **Label** field, select the label of the loop from which you want to continue.
- In the **Loop > Break** action, in the **Label** field, select the label of the loop from which you want to break.

Click the video to see how labeling loops work.

In a bot, if you have multiple nested loops with **Loop** > **Continue** and **Break** actions within the nested loops, and if you have not labeled the loops, then on bot execution, the bot breaks or continues the nearest loop by default.

For example, you have:

- An outer loop and an inner loop nested within the outer loop.
- A **Loop** > **Continue** and **Break** action within the inner loop.

If you have not labeled any of these loops, when you run the bot, the bot will break or continue the nearest loop (the inner loop).

Actions in the Loop package

The following Loop actions are available:

Action	Description
Loop	See Using Loop action on page 2689.
Continue	See Continue action on page 2689. See If package on page 2619.
Break	See Break action on page 2689. See If package on page 2619.

Iterator-related conditions within the Loop action

Select the **Iterator** option to specify the number of times the set of actions will be repeated as part of the Loop action:

Iterator	Description
For each row in CSV/TXT	Repeats the set of actions for each row in the specified CSV or text file and assigns the values in the current row to a record variable. See Using the For each row in CSV/TXT iterator on page 2690.
For each row in Data Table	Repeats the set of actions for each row in the specified table and assigns the values in the current row to a record variable. See Using the For each row in table iterator on page 2691.
For each row in a SQL query dataset	Repeats the set of actions for each row in the specified SQL query dataset and assigns the values in the current row to a record variable. Provide the session name that you have used to establish a connection with the database.

Iterator	Description
For each key in the Dictionary	<p>Repeats the set of actions for each key in the specified Dictionary variable and assigns the name of the current key to a variable.</p> <hr/> <p>Note: When a bot runs a Loop action that contains a Dictionary > Put action, the bot only iterates on the original number of items in a dictionary; it ignores items inserted using the Put action.</p> <hr/>
For each value in the Dictionary	<p>Repeats the set of actions for each value in the specified Dictionary variable and assigns the current value to a variable. Because this variable type can hold various subtypes (String, Number, Boolean, and so on), if you quick-create a variable when configuring the action, the variable is of Any type.</p> <hr/> <p>Note: When a bot runs a Loop action that contains a Dictionary > Put action, the bot only iterates on the original number of items in a dictionary; it ignores items inserted using the Put action.</p> <hr/>
For each mail in mailbox	<p>Repeats the set of actions for each email in the specified mailbox. See Using the For each mail in mail box iterator on page 2459.</p>

Iterator	Description
For each row in worksheet (Excel basic or Excel advanced)	<p>Repeats the set of actions for each row that contains data in a worksheet and assigns the values in the current row to a record variable. Provide the session name that you have used to open the Excel basic or Excel advanced worksheet. Specify whether to repeat the actions for all the rows, specified rows, or a specified cell range. Select a record variable from the Assign the current row to this variable list or create a new one. See Record variable on page 2250.</p> <p>This iterator retrieves cell values as string data types. It supports Excel cell formats, including Number, Percentage, Currency, Scientific, and Date. For example, a value from a cell of Currency formatting retains the currency symbol when passed to a table or record variable.</p> <ul style="list-style-type: none"> You must convert the values to perform non-string operations. In Excel advanced, when you choose loop iterator as For each row in worksheet, you have a Read option to read either the visible text or value of the cell. <p>For example, if the cell has 70% as cell content, Read cell value option will read the value as 70 ignoring the % format whereas Read visible text option will read the content as 70%.</p> <hr/> <p>Recommendation: Use the Read cell value option as reading value from a cell for better performance than reading visible text.</p> <hr/> <p>Use of Global session option to share an Microsoft Excel session using the Excel advanced package is not available with this option.</p> <p>Alternate solution: Use the Get multiple cells action and save the data into a datatable variable and then, use the Loop package with the Data Table option selected.</p>
For each file in folder	<p>Repeats the set of actions for each file in the specified folder and assigns the properties of the current file to a Dictionary variable containing two keys: the <code>name</code> key holds the file name and the <code>extension</code> key holds the file extension.</p> <p>To open files with different extensions, use the variable option to assign the folder path, file name, and file extension. First, create a variable for the folder path, <code>\$\$Folder\$</code>. Then, for the files in the folder path, create two variables, one for file name <code>\$\$name\$</code> and another for file extension <code>\$\$extension\$</code>. To open a file, combine the variables as a string, such as <code>\$\$Folder\$\\$name\$. \$extension\$</code>. For the extension to work with different file types and different open options, you can add conditional logic.</p>
For each folder in folder	<p>Repeats the set of actions for each folder in the specified folder and assigns the current folder name to a String variable.</p> <p>Use the Include all sub-folders option to recursively iterate through each sub-folder within a folder including hidden folders.</p>

Iterator	Description
For each item in the list	<p>Repeats the set of actions for each item in the specified list and assigns the current item to a variable. Specify whether to repeat the action for all items in the list or only for the range of items in the list. Because this variable type can hold various subtypes (String, Number, Boolean, and so on), if you quick-create a variable when configuring the action, the variable is of Any type.</p> <hr/> <p>Note: The index in a list starts from zero. For example, to repeat the action for items from the third position to the sixth position of the list, specify 2 and 5 in the appropriate fields.</p> <hr/>
For n times	Repeats the actions in the container the specified number of times. You can assign the iteration count to a Number variable.
For each value in record	Repeats the actions for each value in the specified record and assigns the current value to a variable. Because this variable type can hold various subtypes (String, Number, Boolean, and so on), if you quick-create a variable when configuring the action, the variable is of Any type..
For each meeting in calendar	Use this option to repeat the set of actions for each meeting in the specified calendar. See Using Microsoft 365 Calendar actions in a loop on page 2714.
For each row in worksheet (Office 365 Excel)	<p>Repeats the set of actions for each row that contains data in a worksheet.</p> <ul style="list-style-type: none"> • Provide the session name that you have used to open the worksheet. • Specify whether to repeat the actions for all the rows or specific rows. • You can assign the values in the current row to a record variable.
For each node in a XML dataset	Repeats the set of actions for each node in an XML dataset and assigns the current node to String variable. Provide the session name that you have used to open the XML file.

While related conditions in the Loop action

You can configure multiple while related conditions within a single Loop action:

1. Click **Add condition**.
2. Select either of the following options:
 - **And:** Both of the conditions must be met for the actions to run.
 - **Or:** Either of the conditions must be met for the actions to run.
3. Select the conditions from the drop-down list.

Select the **While** option to use the following conditions:

While	Description
Application	<p>Use the Application is running or Application is not running condition to run actions based on whether an application is running or not running.</p> <p>Enter the application path or specify the path using a variable along with the amount of time to wait (in seconds) for the condition to be true.</p> <hr/> <p>Note: The Application is running and Application is not running conditions are not applicable for Internet Explorer bots because its corresponding process <code>iexplore.exe</code> runs in the background when Microsoft Edge is launched in IE mode.</p> <hr/>
Boolean	Use this condition to execute actions based on the value of a Boolean variable. Use this condition to compare the values of two Boolean variables or one Boolean variable to a selected Boolean value.
Data table	<p>Use the Data table is empty condition to execute actions based on whether the specified table contains values.</p> <p>Use the Number of rows and Number of columns conditions to execute actions based on whether the number of columns or rows is Equal to, Greater than, or Less than the specified value.</p>
Datetime	Use the Datetime variable condition to execute actions based on whether the value of the source datetime variable is Equal to or Not Equal to , is Greater than or Equal to , or is Lesser than or Equal to the value of the target datetime variable.
Dictionary	<p>Use this condition to repeat the set of actions based on whether the selected dictionary variable contains the specified key.</p> <hr/> <p>Note: The key comparison is case-sensitive.</p> <hr/>

While	Description
File	<p>Use the following conditions to execute the action:</p> <ul style="list-style-type: none"> File date Use this condition to verify the date and time when a file was created or modified. Specify a date or date range using the On a date, Is within last, Is between, or Is before options. For the On a date option, specify a date to verify whether the file was created or modified on that date. For the Is within last option, specify the number of days or time (in hours, minutes, and seconds). Enter the amount of time (in seconds) to wait for this condition to be true. File exists and File does not exist Use these conditions to execute an action based on whether a file exists. For example, if a data file exists, format the file and upload it to a database. File extension Use this condition to check the file extension of a selected file and then execute actions based on the results. Use the File path field to select a file. File size This condition verifies if the specified file is larger, smaller, not the same, or the same as the size you specify. Enter the amount of time (in seconds) to wait for this condition to be true.
Folder does or does not exist	Use these conditions to repeat the set of actions based on whether a folder exists.
Image Recognition	<p>Use these conditions to verify whether:</p> <ul style="list-style-type: none"> Image file is found in the Image file or not. Image file is found in the Window or not. Window is found in the Image file or not. Window is found in the Window or not. <p>For the Window conditions, you can use the Resize window option to specify the window dimensions. This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the bot's ability to identify the target object.</p> <hr/> <p>Note: This option is only available for windows that can be resized. It is not available for Desktop or Taskbar options.</p> <hr/> <p>For the Window conditions, you can use the Preview option to select a specific captured occurrence and position your click location relative to the image.</p>

While	Description
JavaScript	Use the Script is successful or Script is unsuccessful condition to execute actions based the status of the specified JavaScript. Select the file that contains the script and optionally specify the parameters by selecting a list variable.
Legacy automation	<p>The Legacy automation conditions are only used in migrated bots to ensure that they run seamlessly in Automation 360. We do not recommend using these conditions for new bot development. The following conditions to verify the following:</p> <ul style="list-style-type: none"> • Whether Web control exists or not. • Whether Window control exists or not. • Whether Window control is active or not. • Whether Script is successful or not. • Whether Child window exists or not. <p>For the Window control conditions, you can use the Resize window option to specify the window dimensions. This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the bot's ability to identify the target object.</p>
List	Use the List variable condition to execute actions based on whether the specified list variable contains a particular value. The value can be of Number , String , or Boolean data type.
Number	Use the Number variable condition to execute actions based on whether the specified number variable is Equal to or Not Equal to , or is Greater than or Equal to , or is Lesser than or Equal to a particular value.
Ping	Use the Ping is successful or Ping is unsuccessful condition to verify if a machine or server is running, and execute actions based on the result. Enter the amount of time (in seconds) to wait for the condition to be true.
Recorder	<ul style="list-style-type: none"> • Use the Object exists condition to detect an object in a window. Select a window or variable to capture the object. Enter the amount of time (in seconds) to wait for this condition to be true, that is, for the object to be detected. • Use the Object does not exist condition to verify whether a specific object exists in a window, and then based on the result, execute actions. Enter the amount of time (in seconds) to wait for this condition to be true. For example, you can use the Object does not exist condition inside the Loop > While condition to make sure that the bot does not execute the next action until the object on the business application is loaded. <hr/> <p>Note: The Object exists and Object does not exist Recorder conditions support Chromium-based Microsoft Edge with Internet Explorer mode.</p> <hr/>

While	Description
Service	Use the Service is running or Service is not running condition to execute actions based on whether a service is running or not. Select Service list to choose a service from the list of available services.
String	<p>Use the String variable condition to execute actions based on whether the specified source string value is Equal to or Not equal to, or Includes or Does not include the target value.</p> <p>You can select the Match case option to only execute actions if the two strings have matching uppercase and lowercase letters.</p> <p>When you extract text from a Microsoft application, the extracted text contains the /r/n special characters which indicate a new line. Select the Ignore Carriage return option if you want to ignore the /r special character when you compare the text.</p> <p>To create a condition based on whether a string is empty or not empty, compare the source value to an empty target field using the Equal to operator.</p> <p>See Example of using a conditional statement on page 3078.</p>
Task Bot	Use the Task successful or Task unsuccessful condition to execute actions based on the status of the specified Task Bot.
VBScript	Use the Script is successful or Script is unsuccessful condition to execute actions based on the status of the specified Visual Basic script. Select the file that contains the script and optionally specify the parameters by selecting a variable.

While	Description
Window	<p>Use the Window exists or Window does not exist condition to verify if a specific application window is open by entering the Window title or using a variable. Enter the amount of time (in seconds) to wait for the condition to be true. These conditions are used when the window title remains constant and to verify if the specific window is open and execute further actions based on the output.</p> <p>The Window exists condition uses the same window variable to search the specific window from cache. For example, when you open a Yahoo India web page and perform a Click action on the News option on the web page, the action navigates you to another page which changes the title of the window. In this case, when you use the Window exists condition to verify if the window exists, the bot still fetches the Yahoo India web page from the cache and performs action on it because the window is still the same but only the title has changed. For more information on how window variables work, see Your variables (user-defined) on page 2241</p> <p>Use the Window with same title does not exist or Window with same title exist condition to verify whether a window with the same title exists or whether the window title has changed. Enter the amount of time (in seconds) to keep verifying if the condition is true. These conditions are used for window titles that are dynamic. For example, when you open a Google account webpage, enter your username and password to log into your account, the window title changes. If you want to compose a new email as a next action, you can use these conditions before you execute the next action to verify if the window with the same title exists or if the title has changed.</p>

Group conditions

Use the **Add group** option to add multiple Boolean conditions or combine more than one conditions with **And** and **Or** options within a group and when you want the to check multiple conditions at a time before executing a set of .

You can also add a group within a group.

Related tasks

[Example of transferring data from CSV file to Excel worksheet](#) on page 3083

Build a bot that reads data from a CSV file and updates the data in an Excel worksheet, using actions from the CSV/TXT, Excel advanced, IF/ELSE, and Loop packages.

[Example of entering data into a web form from a spreadsheet](#) on page 3074

Build a bot that reads multiple rows of data from an XLSX sheet and enters it into a web form. Use actions from the Excel advanced, Loop, and Recorder packages to build the bot.

[Loop package updates](#) on page 867

Review the updates in released versions of the Loop package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

[Record variable](#) on page 2250

A record variable holds a row of data extracted from a database, spreadsheet, or table in name-field pairs. The fields can store values of Boolean, datetime, number, or string data type.

Related information

[Using loops to control a bot](#)

Continue action

The Continue action in the Loop package enables you to continue the loop in your operation.

Settings

Use the **Continue** action along with the **If** action to skip the current iteration and continue with the next iteration in the loop based on the condition you have specified in the **If** action.

Break action

The Break action in the Loop package enables you to terminate the loop in your operation.

Settings

Use the **Break** action along with the **If** action to terminate the loop based on the condition you have specified in the **If** action. When you terminate the loop, the actions immediately following the **Loop** action run.

Using Loop action

Use the Loop action to repeatedly run a sequence of actions for a specific number of times or until a condition is met.

To repeatedly run a sequence of actions, do the following:

1. Double-click or drag the **Loop** action from the **Actions** palette.
2. Set the desired conditions for the loop.

Option	Action
Select the Iterator option to repeat the sequence of actions for a specific number of times.	Select an option from the Iterator list to specify how many times the sequence of actions is to be repeated. See Loop package on page 2679 for the list of available options.

Option	Action
Select the While option to repeat the sequence of actions until a condition is met.	<p>a) Select an option from the Condition list to specify the condition.</p> <p>b) Select the Check the condition at the end of the iteration to validate the condition at the end of each iteration. This option enables you to ensure that the set of actions run at least one time, even if the condition is not met.</p>

3. Double-click or drag the actions to be repeated within the **Loop**.
4. Optional: Double-click or drag the **Continue** action from the **Loop** package to skip the current iteration and continue with the next iteration of the loop.
5. Click **Save**.

Using the For each row in CSV/TXT iterator

Use the **For each row in CSV/TXT** iterator in the **Loop** action to read the data of each row in a CSV or text file and assign the current row to a record variable. The bot reads the values in each cell as string-type values, even if there are numerical values.

First, open the CSV or text file. [Using the Open action for CSV/TXT file](#) on page 2363

Note: The **For each row in CSV/TXT** iterator only supports CSV/TXT files that conform to the RFC 4180 standard. For more information about the standard, see [Common format and MIME type for CSV files](#).

To use the **For each row in CSV/TXT** iterator in a **Loop** action, do the following:

1. Double-click or drag the **Loop** action from the **Loop** package in the **Actions** palette.
2. Select the **For each row in CSV/TXT** option from the **Iterator** list.
3. Enter the name of the session that you have used to open the CSV or text file in the **Open** action.
4. Select a record variable from the **Assign the current row to this variable** list or create a new one.

Note: If you select an existing record variable, ensure that the column headers capitalization in the CSV or text file match that of the schema of the record variable. [Schema](#) on page 2251

Insert actions to use the values from the CSV or text file in your automation. Use the record variable to retrieve the values by index number or column name. For example, if the first column of the file is titled EmployeeID, to retrieve the value of the first cell of each row enter `$rYourVariableName[0]$` or `$rYourVariableName{EmployeeID}$`.

Note: You must select the **Contains header** option in the **CSV/TXT > Open** action to specify the record values by column name.

For an example, see [Build a Bot Insight dashboard bot](#) on page 3110.

Using the For each row in table iterator

Use the **For each row in table** iterator in the Loop action to read the data of each row in a table variable and assign the current row to a record variable.

First, retrieve the table values and store them to a table variable.

Example: [Example of extracting data from a web table](#) on page 3071

To use the **For each row in table** iterator in a **Loop** action, do the following:

1. Double-click or drag the **Loop** action from the **Loop** package in the **Actions** palette.
2. Select the **For each row in table** option from the **Iterator** list.
3. Select the variable that holds the values from the **Table variable** list.
4. Select a record variable from the **Assign the current row to this variable** list or create a new one.
5. Click **Save**.

Insert actions to use the values from the data table in your automation. Use the record variable to retrieve the values by index number or column name. For example, if the first column of the file is titled EmployeeID, to retrieve the value of the first cell of each row enter `$rYourVariableName[0]$` or `$rYourVariableName{EmployeeID}$`.

Message box package

Use the **Message box** action from the **Message box** package to insert a message box that shows a message when the task runs. For example, you can insert a **Message Box** action to follow a web form so that the action displays the message: `Web Form Filled and Complete`.

For more information, see [Using the Message box action](#) on page 2691.

Use the following examples to learn how to use the **Message box** action when building automations.

- [Build a Go be Great bot](#) on page 3068
Build a basic TaskBot using a Message Box action and a variable.
- [Build a basic bot that uses a desktop application](#) on page 3069
An example of how to build a basic TaskBot that uses the calculator application.

Related reference

[Message Box package updates](#) on page 868

Review the updates in released versions of the Message Box package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using the Message box action

The **Message box** action in the Message Box package enables you to insert a message box that shows a message when the task runs.

1. Double-click or drag the **Message box** action from the **Message box** package in the **Actions** palette.

2. In the **Enter the message box window title** field, enter a window title for the message box.
3. In the **Enter the message to display** field, enter a message that you want the bot to display. This field holds up to 65535 alphanumeric characters, and empty values.

Note: To provide a string that includes a dollar sign (\$), you must enter two dollar signs. For example, if you enter `Pay $$5.00`, the output will be `Pay $5.00`.

4. In the **Scrollbar after lines** field, specify the number of lines at which you want to show a scroll bar.
5. Optional: Select the **Close message box after** option and specify the number of seconds after which you want the message box to close automatically.

Important: Select this check box if the bot will run on an unattended machine.

6. Click **Save**.

Microsoft LUIS NLP package

The **Microsoft LUIS NLP** package contains actions that enable you to connect to and consume the Microsoft Cognitive Services Text Analytics API to identify the language, sentiment, key phrases, and entities. This package supports the following languages: English, Chinese (Simplified), French, German, and Spanish.

Important: This is a beta package and is currently not available with the Automation 360 Enterprise and Cloud editions.

Before you start

You must have an Azure Cognitive Services resource to use these actions. See [Create a Cognitive Services resource using the Azure portal](#).

You also require the following in order to use the actions:

- **Service Endpoint URL:** the endpoint URL that identifies the Azure service.
- **Subscription Key:** the unique key that authenticates Automation Anywhere Enterprise.

Actions in the Microsoft LUIS NLP package

Action	Description
Detect language	Identifies the language of the provided content and returns it in ISO 639-1 language code. The output is stored in a string variable.
Get key phrases	Identifies the main points and returns a list of key phrases. For example, if the input text is about a basketball game, this action returns the names of teams, the name of the venue, and the final score.

Action	Description
Get named entities	<p>Identifies the entities in the provided content such as people, places, organizations, date/time, quantities, branded products, and book titles.</p> <p>The output is stored in a dictionary variable, where each name is a key, and the corresponding entity is the value.</p>
Get sentiment	<p>Analyzes the provided content and returns a sentiment and score.</p> <ul style="list-style-type: none"> • If the score is greater than 0.6, the sentiment is Positive. • If the score is in the 0.2 through 0.6 range, the sentiment is Neutral. • If the score is less than 0.2, the sentiment is Negative. <p>The output is stored in a dictionary variable containing two keys and their corresponding values: <code>sentiment</code> and <code>score</code>.</p>

Mouse package

Use the `Mouse` package to simulate mouse actions.

Automation 360 extension setting

If the bot execution takes longer when you use the `Mouse` package to simulate mouse actions a static page running on the Google Chrome or Microsoft Edge browser, then follow these steps to enable the setting in the Automation 360 extension:

- Click the extensions icon at the top right corner of the browser window.
- Click the vertical ellipses next to the `plugin` and select **Manage extension**.
- Enable the **Allow access to file URLs** option.
- Restart the browser and run the .

Actions in the Mouse package

The `Mouse` package includes the following actions:

Note: When you create an automation that contains **Mouse** actions to capture a UI element, (such as the screen or window), and if the target application is not responding, the bot times out after 30 seconds (default time) and displays a detailed message including: what went wrong at line number and the corresponding corrective action to take.

Action	Description
Click	See Using the Click action on page 2694.
Move	See Using the Move action on page 2696.

Action	Description
Scroll	See Using the Scroll action on page 2696.

Secure recording

When secure recording mode is enabled, bots do not display the target object images after capture. This ensures that sensitive data is not shown.

Note: Although the bots do not display the target images after capture, the images are still stored in the Control Room because they are required to run the bots.

When you record a task in secure recording mode, the **Preview** window temporarily shows an image of the captured area. This image is hidden after you navigate away from the Bot editor window or refresh it.

A user with admin privileges must enable this setting. See [Settings](#) on page 1728.

Related reference

[Screen resolution dependent packages](#) on page 1739

The screen resolution between the Bot Runner and Bot Creator device should be consistent as when resolution-dependent packages are used to build bots, any screen resolution difference between the Bot Creator and Bot Runner device will impact the bots during runtime.

[Mouse package updates](#) on page 877

Review the updates in released versions of the Mouse package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using the Click action

The **Click** action in the Mouse package enables a bot to simulate mouse clicks. This action enables to capture the UI element such as the screen or window, and to specify the click event and click button.

Ensure that the screen scale and resolution of the Bot Creator device is the same as the Bot Runner device. If the screen scale and resolution are different, the bot might fail when deployed to the Bot Runner device.

If you are using Internet Explorer, the bot waits until the browser is completely rendered and is in a ready state before executing the **Click** action.

Follow these steps to add a **Click** action:

1. In the **Actions** palette, double-click or drag the **Click** action from the **Mouse** package.
2. Specify the window in which to capture the mouse click:
Choose from the **Application**, **Browser**, or **Variable** tab.

Option	Description
Application	Select from a list of currently active windows. Note: You can use the Screen option to capture coordinates on the device screen, however we recommend specifying a window because screen sizes can change, which distorts the captured coordinates.
Browser	Select from a list of supported browser tabs. Note: This option supports , Chromium-based , and browsers.
Variable	Select an existing window variable to specify the title of the application window title. Note: This option deactivates the Capture option. Use this option only after you have completed the capture step.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*)-Notepad)` for all window title names starting with `((\w*)-Notepad)`, or use **Pattern** value as `((\w)\s)*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

-
- 3.** Optional: Select the **Resize window** option to specify the window dimensions. This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.
- If the window is maximized when you record the task, this option is not selected.
 - If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

- 4.** Click **Capture coordinate**.
The selected window appears.
- 5.** Drag the mouse to select the click spot and left-click to capture it.
The captured spot appears in the **Preview** section with the coordinates underneath.
- 6.** In the **Button** option, specify the button to click.
Choose from **Left Button**, **Right Button**, or **Middle Button**.
- 7.** In the **Event** option, specify the event.
Choose from **Click**, **Double click**, **Button up**, or **Button down**.
- 8.** Click **Save**.

Using the Move action

The **Move** action in the Mouse package enables you to simulate moving the mouse pointer from one location to another.

Follow these steps to add a **Move** action:

- 1.** In the **Actions** palette, double-click or drag the **Move** action from the **Mouse** package.
- 2.** In the **Mouse from** and **Mouse to** fields, specify the **X** and **Y** coordinates.
- 3.** Click **Capture coordinate** to capture the starting point location.
- 4.** Click **Capture coordinate** to capture the end point location.
- 5.** Optional: In the **Delay in milliseconds** field, specify the total duration of the movement in milliseconds.
- 6.** Click **Save**.

Using the Scroll action

The **Scroll** action in the Mouse package enables you to simulate scrolling the mouse wheel up or down.

Follow these steps to add a **Scroll** action:

- 1.** In the **Actions** palette, double-click or drag the **Scroll** action from the **Mouse** package.
- 2.** In the **Select scroll option**, select the **Up** or **Down** option.

3. In the **Number of iterations** field, specify the number of times to scroll.
4. Optional: In the **Delay in milliseconds** field, specify the total duration of the scrolling in milliseconds.
5. Click **Save**.

Number package

The Number package contains actions that enable you to perform various operations on a number variable. A number variable holds numeric values, including integers and decimals. It holds values from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807, and up to 15 decimal digits.

Actions in the Number package

The actions in the Number package accept a variable as an input and assign the output to a variable. These actions enable you to assign a value to a Number variable, decrement or increment a number, or convert a Number variable to a String variable.

You can use large numbers in number variables or in actions to perform mathematical operations. In the bot editor, use the actions menu (vertical ellipsis at the top-right) to select the **Advanced settings > Enable improved number support**.

Note: Ensure you update to the latest version of the package to use this feature.

The Number package includes the following actions:

Action	Description
Assign	See Assign action in Number on page 2698
Decrement	See Decrement action in Number on page 2698
Increment	See Increment action in Number on page 2698
Random	See Random action in Number on page 2699
To string	See To string action in Number on page 2699

Related reference

[Number package updates](#) on page 879

Review the updates in released versions of packages such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Assign action in Number

The Assign action in the Number package enables you to assign a specified number or result of an expression to a user-defined Number variable. You can use expressions built using the +, -, *, and / operators and use parentheses to group expressions. For example, $(3*4)+5$ or $(\$Variable2*\$Variable3)/\$Variable1$.

Settings

- In the **Select the source number variable/value**, enter a number or select a predefined Number variable.
- In the **Select the destination number variable**, select a predefined Number variable or create a new one to hold the output.

Decrement action in Number

The Decrement action in the Number package enables you to decrement (decreases by set intervals) a number by a user-specified value.

Settings

- In the **Enter number** field, enter a number or select a predefined Number variable.
- In the **Enter decrement value** field, enter the decrement value or select a predefined Number variable.
- In the **Assign the output to variable** field, select a predefined Number variable or create a new one to hold the output.

Increment action in Number

The Increment action in the Number package enables you to increment (increases by set intervals) a number by a user-specified value.

Settings

- In the **Enter number** field, enter a number or select a predefined Number variable.
- In the **Enter increment value** field, enter the increment value, the value must be greater than zero or select a predefined Number variable.
- In the **Assign the output to variable** field, select a predefined Number variable or create a new one to hold the output.

Random action in Number

The Random action in the Number package enables you to generate a random integer from a user-specified range and assign it to a number variable.

Settings

- In the **Beginning of range** field, enter a number or select a predefined number variable.

Note: This field accepts values in the range of -9,223,372,036,854,775,808 through 9,223,372,036,854,775,807, and up to 15 decimal digits.

- In the **End of range** field, enter a number or select a predefined number variable that is greater than the value in the **Beginning of range** field.

Note: This field accepts values in the range of -9,223,372,036,854,775,808 through 9,223,372,036,854,775,807, and up to 15 decimal digits.

- Enter the number of digits after the decimal by selecting the **Specify number of decimals** check box.
- In the **Save the outcome to a variable** field, select a predefined Number variable or create a new one to hold the output.

To string action in Number

The To string action in the Number package enables you to convert a user-specified number to a string.

Settings

- In the **Enter number** field, enter a number or select a predefined Number variable.
- In the **Enter number of digits after decimal** field, enter the amount of digits after the decimal. To remove all the digits after the decimal, leave the default value of 0.
- In the **Assign the output to variable** field, select a pre-defined String variable or create a new one to hold the output. You can use prompt-assignment during building and testing of the bot.

Important: Ensure that you reassign the values from prompt-assignment to a user-created variable before deploying the bot into production.

OCR package

The OCR package contains actions that enable you to extract text from images or applications.

The OCR package enables you to:

- Extract text from a window or a specific area of an application.
- Extract text from images or files stored on a local machine, a website, or the Control Room folder.

- Filter extracted text and store it as a variable.

Note: You can extract text from images in .jpeg, .jpg, .bmp, .gif, and .png formats.

ABBYY FineReader 12.2.27.12 is installed along with A2019 and does not require any additional setup.

Actions in the OCR package

The OCR package includes the following actions:

Action	Description
Capture image by path	See Using Capture image by path action on page 2701.
Capture image by url	See Using Capture image by URL action on page 2702.
Capture window	See Using Capture window action from OCR package on page 2702.
Capture area	See Using Capture area action from OCR package on page 2704.

Note:

Below is a sample .ini template file that you can use to load profiles. You can use the parameters and set their values, as required. You can also add new parameters supported by ABBYY Fine Reader Engine.

```
;Sample parameter1
[BarcodeParams]
;Parameter value
EnableAdvancedExtractionMode=True
;Sample parameter2
[ObjectsExtractionParams]
;Parameter value
DetectTextOnPictures=True
```

For detailed information about pre-defined profiles specifications, see [ABBYY Profiles](#).

Secure recording

When secure recording mode is enabled, bots do not display the target object images after capture. This ensures that sensitive data is not shown.

Note: Although the bots do not display the target images after capture, the images are still stored in the Control Room because they are required to run the bots.

When you record a task in secure recording mode, the **Preview** window temporarily shows an image of the captured area. This image is hidden after you navigate away from the Bot editor window or refresh it.

A user with admin privileges must enable this setting. See [Settings](#) on page 1728.

Related reference

[Screen resolution dependent packages](#) on page 1739

The screen resolution between the Bot Runner and Bot Creator device should be consistent as when resolution-dependent packages are used to build bots, any screen resolution difference between the Bot Creator and Bot Runner device will impact the bots during runtime.

[OCR package updates](#) on page 880

Review the updates in released versions of the OCR package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using Capture image by path action

Use the **Capture image by path** action to extract text from an image on a device or a folder in the Control Room. The extracted text can assigned as a variable.

Follow these steps to use the **Capture image by path** action:

1. In the **Actions** palette, double-click or drag the **Capture image by path** action from the **OCR** package.
2. In the **Image path** field, select an option:
 - **Control Room file**: Uses a file that is available on the Control Room.
 - **Desktop file**: Uses a file that is available on a device.
 - **Variable**: Uses a file variable to specify the file location.

Note: If you use a high resolution image, text extraction by OCR might be partial or inaccurate. For best results while extracting text from an image using OCR, ensure that you use images with lower resolution (such as 200 dpi or 300 dpi).

3. Select the **Filter the captured text** check box to filter the captured text.
Specify the text to filter out in the **Before** and **After** fields. For example, if the extracted text is `Name: ABC Inc. Location:`, to retrieve `ABC Inc.`, you must specify `Location:` in the **Before** field and `Name:` in the **After** field.
4. Select the **Trim the captured text** check box to trim the extra spaces.
5. Select the **Load Profile** check box and select an option to load the locale based on the ABBYY profile:

Note: ABBYY FineReader 12.2.27.12 is installed along with A2019 and does not require any additional setup.

- **Control Room file**: Uses a file that is available on the Control Room.
 - **Desktop file**: Uses a file that is available on a device.
 - **Variable**: Uses a file variable to specify the file location.
6. In the **Select locale** list, select the language of the device.

Note: Currently, only English, Japanese, and Russian locales are supported. If you have selected an option from the **Select locale** list and the **Load Profile** option, the system considers the locale based on the **Load Profile** selection.

7. In the **Assign value to variable** list, select a string variable.
8. Click **Save**.

Using Capture image by URL action

Use the **Capture image by url** action to extract text from an online image. You can filter the extracted text and assign it to a string variable.

Follow these steps to use the **Capture image by url** action:

1. In the **Actions** palette, double-click or drag the **Capture image by url** action from the **OCR** package.
2. In the **Image url** field, specify the URL.

Note: A URL of an image on a shared drive or an FTP server is not supported.

3. Select the **Filter the captured text** check box to filter the captured text.
Specify the text to filter out in the **Before** and **After** fields. For example, if the extracted text is **Name: ABC Inc. Location:**, to retrieve **ABC Inc.**, you must specify **Location:** in the **Before** field and **Name:** in the **After** field.
4. Select the **Trim the captured text** check box to trim the extra spaces.
5. Select the **Load Profile** check box and select an option to load the locale based on the ABBYY profile:

Note: ABBYY FineReader 12.2.27.12 is installed along with A2019 and does not require any additional setup.

- **Control Room file:** Uses a file that is available on the Control Room.
- **Desktop file:** Uses a file that is available on a device.
- **Variable:** Uses a file variable to specify the file location.

6. In the **Select locale** list, select the language of the device.

Note: Currently, only English, Japanese, and Russian locales are supported. If you have selected an option from the **Select locale** list and the **Load Profile** option, the system considers the locale based on the **Load Profile** selection.

7. In the **Assign value to variable** list, select a string variable.
8. Click **Save**.

Using Capture window action from OCR package

Use the **Capture window** action to extract text from an application window. You can filter the extracted text and assign it to a string variable.

Note: When you use the **Capture window** action to extract text from an application window and, if the target application is not responding, the bot times out after 30 seconds (default time) and displays a more detailed message including: what went wrong at line number and the corresponding corrective action to take.

Follow these steps to use the **Capture window** action:

1. In the **Actions** palette, double-click or drag the **Capture window** action from the **OCR** package.
2. In the **Window title** field, select an option:

- **Window:** Captures a window on a desktop. In the **Window title** field, specify the application title.
- **Variable:** Inserts an existing window variable. Click **Variable** tab to create a new string variable.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `(\w*)-Notepad` for all window title names starting with `(\w*)-Notepad`, or use **Pattern** value as `(\w)\s)*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

3. Optional: Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.

- If the window is maximized when you record the task, this option is not selected.
 - If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.
-

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

4. In the **Wait before capturing the image (ms)** field, specify the delay time.

Recommendation: If you are capturing in a window that is accessed using Remote Desktop Protocol (RDP), set a minimum delay time of 1000 milliseconds to give the window time to load.

5. Select the **Filter the captured text** check box to filter the captured text.
Specify the text to filter out in the **Before** and **After** fields. For example, if the extracted text is **Name: ABC Inc. Location:**, to retrieve **ABC Inc.**, you must specify **Location:** in the **Before** field and **Name:** in the **After** field.
 6. Select the **Trim the captured text** check box to trim the extra spaces.
 7. Select the **Load Profile** check box and select an option to load the locale based on the ABBYY profile:
-

Note: ABBYY FineReader 12.2.27.12 is installed along with A2019 and does not require any additional setup.

- **Control Room file:** Uses a file that is available on the Control Room.
 - **Desktop file:** Uses a file that is available on a device.
 - **Variable:** Uses a file variable to specify the file location.
8. In the **Select locale** list, select the language of the device.
-

Note: Currently, only English, Japanese, and Russian locales are supported. If you have selected an option from the **Select locale** list and the **Load Profile** option, the system considers the locale based on the **Load Profile** selection.

9. In the **Assign value to variable** list, select a string variable.
10. Click **Save**.

Using Capture area action from OCR package

Use the **Capture area** action to extract text from a specific area in an application window. You can filter the extracted text and assign it as a variable.

Note: When you use the **Capture area** action to extract text from a specific area in an application window and, if the target application is not responding, the bot times out after 30 seconds (default time) and displays a more detailed message including: what went wrong at line number and the corresponding corrective action to take.

To improve the accuracy of extracting text from a specific area in an application window, see this [Predefined profiles specification](#)

Follow these steps to use the **Capture area** action:

1. In the **Actions** palette, double-click or drag the **Capture area** action from the **OCR** package.
2. In the **Window title** field, select an option:
 - **Window:** Captures a window on a desktop. In the **Window title** field, specify the application title.
 - **Variable:** Inserts an existing window variable.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `(\w*)-Notepad` for all window title names starting with `(\w*)-Notepad`, or use **Pattern** value as `(\w)\s*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

3. Optional: Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.

- If the window is maximized when you record the task, this option is not selected.
- If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

4. Specify the **X, Y, Width**, and **Height** coordinates.

5. Click **Capture region**.

The bot captures text from the visible area of the screen even if the target area is below the visible screen.

6. In the **Wait before capturing the image (ms)** field, specify the delay time.

Recommendation: If you are capturing in a window that is accessed using Remote Desktop Protocol (RDP), set a minimum delay time of 1000 milliseconds to give the window time to load.

7. Select the **Filter the captured text** check box to filter the captured text.
Specify the text to filter out in the **Before** and **After** fields. For example, if the extracted text is **Name: ABC Inc. Location:**, to retrieve **ABC Inc.**, you must specify **Location:** in the **Before** field and **Name:** in the **After** field.
8. Select the **Trim the captured text** check box to trim the extra spaces.
9. Select the **Load Profile** check box and select an option to load the locale based on the ABBYY profile:

Note: ABBYY FineReader 12.2.27.12 is installed along with A2019 and does not require any additional setup.

- **Control Room file:** Uses a file that is available on the Control Room.
 - **Desktop file:** Uses a file that is available on a device.
 - **Variable:** Uses a file variable to specify the file location.
10. In the **Select locale** list, select the language of the device.

Note: Currently, only English, Japanese, and Russian locales are supported. If you have selected an option from the **Select locale** list and the **Load Profile** option, the system considers the locale based on the **Load Profile** selection.

11. In the **Assign value to variable** list, select a string variable.
12. Click **Save**.

Microsoft 365 Calendar package

This package contains actions that enable you to automate meeting-related tasks in Microsoft 365 Calendar.

Before you start

Note: Microsoft has deprecated EWS API for Exchange Online and has recommended users to move to Graph API. Starting from Automation 360 v.29, Office 365 Calendar package is now called Microsoft 365 Calendar package. Although the package name has changed, the functionality remains the same. So your existing bots from previous releases will continue to work as expected after an update to Automation 360 v.29.

Perform the following actions within the Microsoft 365 Calendar package as part of using the set of available actions:

1. Use the **Connect** action to establish a connection to the Microsoft 365 server.
See [Using Connect action in Microsoft 365 Calendar package](#) on page 2709.

Note: Microsoft 365 packages do not currently support Multi-Factor Authentication or Single Sign-on.

2. Use a combination of actions available in this package to automate tasks.
-

Note: To use actions from other Microsoft 365 packages, establish a connection using the **Connect** action from that package.

3. Use the **Disconnect** action to terminate the connection.
-

Actions in the Microsoft 365 Calendar package

The Microsoft 365 Calendar package contains the following actions:

Action	Description
Add attachment	See Add attachment action in Microsoft 365 Calendar on page 2708
Add attendees	See Add attendees action in Microsoft 365 Calendar on page 2708
Cancel meeting	See Cancel meeting action in Microsoft 365 Calendar on page 2709
Connect	Establishes a connection with the Office 365 server using your organization's client ID and tenant ID, and user credentials. See Using Connect action in Microsoft 365 Calendar package on page 2709.
Create meeting	See Using the Create Meeting action on page 2711.
Delete attendees	See Delete attendees action in Microsoft 365 Calendar on page 2712
Delete meeting information	See Delete meeting information action in Microsoft 365 Calendar on page 2712
Disconnect	Terminates the connection with the Office 365 server. Enter the session name that you used in the Connect action. Insert this action at the end of automation sequences that use actions from this Office 365 package. See Disconnect action for Office 365 packages on page 2713.
Get available meeting slot(s)	See Using the Get available meeting slots action on page 2713.
Modify meeting	See Modify meeting action in Microsoft 365 Calendar on page 2713

Action	Description
Respond to meeting	See Respond to meeting action in Microsoft 365 Calendar on page 2714

Note: Some of the actions must be used within a **Loop** action to apply the action to each meeting in the calendar. See [Using Microsoft 365 Calendar actions in a loop](#) on page 2714.

Related reference

[Microsoft 365 Calendar package updates](#) on page 869

Review the updates in released versions of the Microsoft 365 Calendar package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Add attachment action in Microsoft 365 Calendar

The **Add attachment** action in the Microsoft 365 Calendar package enables you to add one or more attachments to a meeting.

Settings

Use this action within a **Loop** action to repeat this operation for each meeting in the calendar. See [Loop package](#) on page 2679.

- Provide the session name that you used in the **Connect** action.
- Select the files to attach from the Control Room or your desktop, or insert a file variable. Separate each file path with a comma.

Add attendees action in Microsoft 365 Calendar

The **Add attendees** action in the Microsoft 365 Calendar package enables you to add one or more attendees to a meeting and specifies whether attendance is optional or required.

Settings

During run time, this triggers an email notification to meeting attendees. Use this within a **Loop** to repeat this operation for each meeting in the calendar. See [Loop package](#) on page 2679.

- Provide the session name that you used in the **Connect**.
- Enter the attendee emails into the **Required** or **Optional** fields. Separate each email with a comma.

Cancel meeting action in Microsoft 365 Calendar

The **Cancel meeting** action in the Microsoft 365 Calendar package enables you to cancel the meeting.

Settings

During run time, this triggers an email notification to meeting attendees. Use this within a **Loop** to repeat this operation for each meeting in the calendar. See [Loop package](#) on page 2679.

Using Connect action in Microsoft 365 Calendar package

Use the **Connect** action in the Microsoft 365 Calendar package to establish a connection with the Microsoft 365 server using your organization's (client ID and tenant ID) and user credentials.

All the fields in the **Connect** action accepts a credential from the Credential Vault or a user-input value.

Note:

- The **Connect** action does not currently support MFA or SSO.
- For the **Connect** action, ensure that the administrator consent for the permissions is granted.

-
1. Log in to the [Azure portal](#) using your Microsoft 365 credentials.
 2. Register your application with the Microsoft identity platform to obtain the client ID and tenant ID. See [Register your app](#).
 3. Grant the required permissions for Microsoft Graph to the application.
See [Permissions for application](#) on page 2710.

Note: For your app registration on Azure portal, navigate to **Authentication > Advanced Settings > Allow public client flows** and ensure that you select **Yes**.

4. To add a client secret, you must first subscribe to Azure. See [Subscribe to Azure](#).
5. Add a client secret. See [Add a client secret](#).

For an example on how to setup and connect to the Microsoft 365 OneDrive package, see [Setup Azure App to connect using Microsoft OneDrive package \(A-People login required\)](#).

1. In the Actions palette, double-click or drag the **Connect** action from the package you want to use.
2. In the **Microsoft 365 Calendar user session** field, enter a session name.
(Optional) Click the **Insert a value** icon to select an existing variable.

Note: Enter this session name in subsequent actions in this package.

3. Use the **Username** field to select one of the following options to specify the Microsoft 365 User Email:

- **Credential:** To use a value available in the Credential Vault.
Click the **Pick** button to select a credential.
- **Variable:** To use a value that is stored as a credential variable.
- **Insecure string:** To manually specify the values.
(Optional) Click the Insert a value icon to insert an existing variable.

Note: The information about **Credential**, **Variable** and **Insecure string** fields remain the same across all the other options.

4. Use the **Password** field to specify the Microsoft 365 password:
5. Use the **Tenant ID** field to enter the unique ID for your Microsoft 365 subscription or insert it from the Credential Vault.
6. Use the **Client ID** field to enter the Office 365 client or insert it from the Credential Vault.
7. Use the **Client Secret Key** field to enter your access token or insert it from the Credential Vault.
8. Click **Save**.

Permissions for application

After registering Office 365, you must grant certain permissions to the application. These permissions are required to enable Office 365 packages to perform various operations.

To grant permissions to an application, see [Add permissions](#).

Note: You must be the co-owner of the application for which you are configuring permissions.

The following [Delegated permissions](#) for Microsoft Graph are required for Office 365 packages:

Common permissions	
	openid
	offline_access
	User.Read
	User.ReadBasic.All
One Drive	
	Files.ReadWrite.All
	Sites.ReadWrite.All
Calendar	
	Calendars.Read
	Calendars.Read.Shared
	Calendars.ReadWrite
Email	
	Mail.Read
	Mail.ReadWrite

	MailboxSettings.Read
	MailboxSettings.ReadWrite
Directory	
	Directory.AccessAsUser.All
	Directory.ReadWrite.All

Apart from the above permissions, you can grant additional permissions based on your requirements. See, [Microsoft Graph permission reference](#).

Using the Create Meeting action

Use the **Create Meeting** action to specify a meeting agenda, attachments, attendees, duration, location, recurrence, and title. During run time, this action sends an invitation email to meeting attendees.

This action uses two Datetime variables to set the meeting start and end. Define the values before you start. The recurrence option also uses two Datetime variables to set the start and end. For more information, see [Your variables \(user-defined\)](#) on page 2241.

To create a meeting, do the following:

1. Enter the session name that you used in the **Connect** action.
2. Enter the calendar name.
This field is case-sensitive.
The Calendar appears and is the default Microsoft Office setting.
3. Specify the meeting start date and time.
Select a DateTime variable from the drop-down list.
4. Specify the meeting end date and time.
Select a DateTime variable with a value that is the same or after the start time.
5. Optional: Mark the **All day meeting** option.
For an all day meeting, ensure that there is a one-day difference between the start and end dates.
6. Enter attendee email addresses, separated by commas.
7. Optional: Enter the following details:
 - Attach a file from the Control Room, Desktop, or insert a File variable.
 - Enter a meeting title.
 - Enter a meeting location.
 - Enter an agenda.
 - Set a reminder.
 - Set a recurrence with the following options:
 - Select the recurrence type: **Daily**, **Weekly**, **Monthly**, or **Yearly**.
 - For **Weekly** recurrence, mark the days of the week on which the meeting takes place.
 - For **Monthly** recurrence, either enter the numerical date or select a day.

For example, to schedule a meeting that takes place on the twenty-fifth day of the month enter 25 in the **Specific date** field.

Note: If you enter 31 in the **Specific date** field, for the months with less than 31 days, the meeting will schedule for the last day of the month.

To schedule it for the last Monday of the month, select **Last** from the **Occurrence** drop-down list and **Monday** from the **Weekday** drop-down list.

- For **Yearly** recurrence, either enter the numerical date and month or select a day and month.

For example, to schedule a meeting that takes place on March 15, enter 15 in the **Specific Date** field and **March** in the **Month** field. To schedule it for the second Friday in March, select **Second** from the **Occurrence** drop-down list, select **Friday** from the **Weekday** drop-down list, and **March** from the **Month** drop-down list.

- Enter the recurrence frequency.
- Specify the recurrence start by selecting a DateTime variable from the drop-down list.
- If the recurrence has an end date, select a DateTime variable from the drop-down list.

Delete attendees action in Microsoft 365 Calendar

The **Delete attendees** action in the Microsoft 365 Calendar package enables you to delete attendees from a meeting.

Settings

During run time, this action triggers an email notification to meeting attendees. Use this within a **Loop** to repeat this operation for each meeting in the calendar. See [Loop package](#) on page 2679.

- Provide the session name that you used in the **Connect** .
- Select an option to delete: **meeting** or **attendees**. To delete attendees, provide the email addresses of the attendees, separated by commas.

Delete meeting information action in Microsoft 365 Calendar

The **Delete meeting information** action in the Microsoft 365 Calendar package enables you to delete information related to a meeting such as the title or location.

Settings

Use this within a **Loop** to repeat this operation for each meeting in the calendar. See [Loop package](#) on page 2679.

- Provide the session name that you used in the **Connect** .
- Select the meeting information to delete. The options are:
 - Title

- Location
- Agenda
- Reminder
- Recurrence
- Is all day

Disconnect action for Office 365 packages

Use the Disconnect action from the specific Office 365 package to terminate the connection from the Office 365 application.

Settings

Enter the user session that you provided in the **Connect** action.

Using the Get available meeting slots action

Use the **Get available meeting slots** action to retrieve available time slots for attendees in a specified date and time range. This action supports scheduling across time zones.

This action considers a time slot as available if it is within an attendee's working hours and if the attendee has not already accepted a meeting for that time. If an attendee tentatively responds or does not respond to an invitation, this action considers them available.

To retrieve available time slots, perform the following steps:

1. Enter the session name that you used in the **Connect** action.
2. Enter the email addresses of the attendees, separated by commas.
3. Enter the duration of the meeting in minutes.
4. Specify the range start date and time by selecting a DateTime variable from the drop-down list.
5. Specify the range end date and time by select a DateTime variable with a value that is the same or after the start time.
6. Optional: Select the **Check for timeslots outside working hours** option.
7. Select a Table variable from the drop-down list.
8. Click **Save**.

Modify meeting action in Microsoft 365 Calendar

The **Modify meeting** action in the Microsoft 365 Calendar package enables you to modify information for a meeting.

Settings

Use this within a **Loop** to repeat this operation for each meeting in the calendar. See [Loop package](#) on page 2679.

- Provide the session name that you used in the **Connect** .
- Modify any of the following:
 - Meeting start or end date.
 - Convert the meeting to all day.
 - Revise the meeting title.
 - Revise the agenda.
 - Update the location.
 - Update the reminder.
 - Update the recurrence, frequency, start date, and end date.

Respond to meeting action in Microsoft 365 Calendar

The **Respond to meeting** action in the Microsoft 365 Calendar package enables you to respond to a meeting as accepted, rejected, or tentative.

Settings

You can also add a message to the response.

Use this within a **Loop** to repeat this operation for each meeting in the calendar. See [Loop package](#) on page 2679.

Using Microsoft 365 Calendar actions in a loop

You must use certain Microsoft 365 Calendar actions within a **Loop** action.

This action uses two Datetime variables to set the meeting start and end. Define the values before you start. For more information, see [Your variables \(user-defined\)](#) on page 2241.

To use a Microsoft 365 Calendar action within a loop, follow these steps:

1. Double-click or drag the **Loop** action from the **Loop** package in the **Actions** palette.
2. Select the **For each meeting in calendar** iterator.
3. Enter the session name that you used in the **Connect** action.
4. Enter the calendar name.
This field is case-sensitive.
The Calendar appears and is the default Microsoft Office setting.
5. Select whether to loop through **All meetings in the calendar** or only meetings with the specific title.
6. Specify the meeting start date and time.
Select a DateTime variable from the drop-down list.
7. Specify the meeting end date and time.
Select a DateTime variable with a value that is the same or after the start time.
8. Optional: Enter the location.
9. Optional: Enter the duration in minutes.
10. Optional: Mark the **All day meeting** option.

For an all day meeting, ensure that there is a one-day difference between the start and end dates.

11. Optional: Enter the meeting owner's email address.
12. Select or create a record variable to hold the output.

Microsoft 365 Excel package

The Microsoft 365 Excel package contains actions that enable you to automate tasks in the online version of Microsoft Excel.

Choosing the Excel package in Automation 360

Important: Microsoft has deprecated EWS API for Exchange Online and has recommended users to move to Graph API. Starting from Automation 360 v.29, Office 365 Excel package is now called Microsoft 365 Excel package. Although the package name has changed, the functionality remains the same. So your existing bots from previous releases will continue to work as expected after an update to Automation 360 v.29.

Automation 360 includes packages to support three types of Microsoft Excel usage. For optimal results, use the package that corresponds to the type of Excel that is available on the device you are running bots on.

- No Excel installed: If you do not have Microsoft Excel installed on the device on which you are running bots to automate Excel-related processes, use the Excel basic package.
- Desktop Excel installed: If you have a desktop version of Microsoft Excel installed on your computer, use the Excel advanced package in your bots.
- Online Microsoft 365 Excel only: If you are using Microsoft Excel 365 on a web browser, use the Microsoft 365 Excel package for automating tasks related to Excel.

Before you start

1. Use the **Connect** action to establish a connection to the Microsoft 365 server.
See [Using Connect action in Microsoft 365 Calendar package](#) on page 2709.
-

Note: Microsoft 365 packages do not currently support Multi-Factor Authentication or Single Sign-on.

2. Use the **Open** action to select a workbook, or the **Create** action to create a new workbook. See [Workbook operations in Microsoft 365 Excel](#) on page 2728.
 3. Optional: If the workbook contains more than one worksheet, use the **Activate sheet** action to specify which worksheet to use.
 4. Use a combination of actions available in this package to automate tasks.
-

Note: To use actions from other Microsoft 365 packages, establish a connection using the **Connect** action from that package.

5. Use the **Close** action to exit from the workbook.

- Use the **Disconnect** action to terminate the connection.

Actions in the Microsoft 365 Excel package

The actions in the Microsoft 365 Excel package enable you to perform the following operations:

Operations	Description
Cell	Perform operations related to cell and range operations, such as append, delete, format, get properties, and insert. See Cell operations in Microsoft 365 Excel on page 2716
Row and column	Perform operations related to column and row operations such as autofit, delete, and read. See Column/Row operations in Microsoft 365 Excel on page 2723.
Table	Perform operations related to the table operations such as create, delete, filter, get properties, rename, and sort. See Table operations in Microsoft 365 Excel on page 2726.
Workbook	Automate opening, closing, and creating a workbook. See Workbook operations in Microsoft 365 Excel on page 2728.
Worksheet	Perform operations related to worksheet operations, such as activate, delete, find, get worksheet names, hide, retrieve worksheet count, and show. See Worksheet operations in Microsoft 365 Excel on page 2729.

Cell operations in Microsoft 365 Excel

The Microsoft 365 Excel package contains actions that you can use to automate tasks related to cell and range operations, such as append, delete, format, get properties, and insert.

The Microsoft 365 Excel package includes the following actions:

Action	Description
Delete cell	See Delete cell action in Microsoft 365 Excel on page 2717.
Delete range	See Delete range action in Microsoft 365 Excel on page 2718.
Format cell	See Using the Format cell action on page 2718.
Get cell	See Get cell action in Microsoft 365 Excel on page 2719.
Get cell/text color	See Using the Get cell/text color action on page 2719.
Get multiple cells	See Get multiple cells action in Microsoft 365 Excel on page 2720.
Go to cell	See Go to cell action in Microsoft 365 Excel on page 2720.
Insert cell	See Insert cell action in Microsoft 365 Excel on page 2720.
Insert range	See Insert range action in Microsoft 365 Excel on page 2721.
Paste cell	See Paste cell action in Microsoft 365 Excel on page 2721.
Read cell format	See Read cell format action in Microsoft 365 Excel on page 2721.
Read cell formula	See Read cell formula action in Microsoft 365 Excel on page 2722.
Set cell	See Set cell action in Microsoft 365 Excel on page 2722.
Set cell color	See Set cell color action in Microsoft 365 Excel on page 2722.
Set cell formula	See Set cell formula action in Microsoft 365 Excel on page 2723.

Delete cell action in Microsoft 365 Excel

The Delete cell action in Microsoft 365 Excel enables you to delete an active cell or a specific cell from the current worksheet.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select either the active cell or a specific cell. If you select **Specific cell**, enter the cell location. For example **A1**.
- From the delete options, select one of the following options:
 - **Shift cells left**: Deletes the specified cell and shifts the cell one position to left.
 - **Shift cells up**: Deletes the specified cell and shifts the cell one position up.
 - **Entire row**: Deletes the entire row that contains the cell that you have specified to delete.
 - **Entire column**: Deletes the entire column that contains the cell that you have specified to delete.

Delete range action in Microsoft 365 Excel

The Delete range action in Microsoft 365 Excel enables you to delete a specific range of cells.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter the cell range. For example **A1 : B4**. This deletes an area consisting of the first four rows by the first two columns.
- Specify whether to shift the cells up or left.
 - **Shift cells up**: Deletes the specified cells and shifts the cells up by the number of rows deleted.
 - **Shift cells left**: Deletes the specified cells and shifts the cells left by the number of columns deleted.

Using the Format cell action

Use the **Format cell** action to set the format of a cell or group of cells.

To format a cell or group of cells, do the following:

1. Double-click or drag the **Format cell** action.
2. Enter the name of the session used to open the workbook with the **Open** .
3. Select the **Active cell**, **Specific cell**, or **Multiple cells** option and provide cell location or cell range, as necessary.
4. Mark the **Font** option to modify any of the following:
 - Font name
 - Font size (between 8 and 72)
 - Bold or italicize
 - Underline
 - Font color (accepts color name or hex value). For a list of color names and corresponding hex values, see [Frequently used cell colors](#) on page 2718.
5. Mark the **Alignment** option, then use the drop-down lists to modify the vertical or horizontal alignment.
6. Mark the **wrap text** option to expand the cell(s) vertically to show long strings of text.
7. Mark the **Merge Type** option to select the any of the following operations:
 - Merge and center
 - Merge across
 - Merge cells
 - Unmerge
8. Click **Save**.

Frequently used cell colors

Review the color names and their corresponding hex values you can use to set a cell color for a cell or text within a cell in a worksheet. These are the most frequently used options for formatting worksheets.

Name	Hex
Aqua	#00FFFF
Black	#000000
Blue	#0000FF
Gray	#808080
Green	#008000
Fuchsia	#FF00FF
Lime	#00FF00
Maroon	#800000
Navy	#000080
Olive	#808000
Purple	#800080
Red	#FF0000
Silver	#C0C0C0
Teal	#008080
White	#FFFFFF
Yellow	#FFFF00

Get cell action in Microsoft 365 Excel

Use the Get cell action in Microsoft 365 Excel to retrieve the value of a cell.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select either an **Active cell** or **Specific cell**. If you select a specific cell, enter the cell location.
- Assign the output to a String variable. To perform mathematical operations, convert the string to a number using the **String > To number**. See [To number action](#) on page 2973.

Using the Get cell/text color action

Use the **Get cell/text color** action to get the color of the background or text in a cell. This action retrieves the color of a cell as RGB values. For example, if the background or text in a cell is of red color, the value retrieved is 255,0,0.

To get the color of the background or text in a cell, do the following:

1. Double-click or drag the **Get cell/text color** action.
2. Enter the name of the session used to open the workbook with the **Open** .
3. Select the **Active cell** option to get the color from the current active cell or the **Specific cell** option to get the color from the address of the cell you have specified.

4. Select the **Cell color** option to get the background color of the cell, the **Text color** option to get the color of the text, or both.
5. Specify whether to retrieve the cell color by name or as an RGB value.
6. Select a variable from the **Assign the output to variable** list to assign the cell/text color to a List variable.
7. Click **Save**.
If both cell and text colors are retrieved, the List variable contains the cell color at index 0 and text color at index 1.

Get multiple cells action in Microsoft 365 Excel

Use the Get multiple cells action in Microsoft 365 Excel to retrieve the values of multiple cells within a worksheet and assign the output to a variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select either the **Multiple cells** or **All cells** option. If you select **Multiple cells**, enter the cell range. For example, if you enter A1 : D1, values of the first four cells in the top row are retrieved.
- Assign the output to a String variable. To convert the string to a number, use the **String > To number** action. See [To number action](#) on page 2973.

Go to cell action in Microsoft 365 Excel

Use the Go to cell action in Microsoft 365 Excel to move the cursor to a specific cell in the worksheet.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select from the following cell options:
 - **Specific cell**: Moves to the specified cell address.
 - **One cell to the left**: Moves one cell left.
 - **One cell to the right**: Moves one cell right.
 - **One cell above**: Moves one cell up.
 - **One cell below**: Moves one cell down.
 - **Beginning of the row**: Moves to the first cell in the same row.
 - **End of the row**: Moves to the last cell that contains data in the same row.
 - **Beginning of the column**: Moves to the first cell in the same column.
 - **End of the column**: Moves to the last cell that contains data in the same column.

Insert cell action in Microsoft 365 Excel

Use the Insert cell action in Microsoft 365 Excel to insert a value to an active cell or a specific cell in the current worksheet without overwriting the existing value.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select either **Active cell** or **Specific cell**. If you select **Specific cell**, enter the cell location, for example A1.
- After inserting the cell, you can perform these operations:
 - **Shift cell > Down**: Shifts the existing values down by the specified number of rows.
 - **Shift cell > Right**: Shifts the existing values right by the specified number of columns.

Insert range action in Microsoft 365 Excel

Use the Insert range action in Microsoft 365 Excel to insert a range in the current worksheet without overwriting the existing value.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter the cell range, for example A1 :B4. This inserts a range of cells consisting of the first four rows by the first two columns.
- After inserting the cell, you can perform these operations:
 - **Shift cell > Down**: Shifts the existing values down by the specified number of rows.
 - **Shift cell > Right**: Shifts the existing values right by the specified number of columns.

Paste cell action in Microsoft 365 Excel

Use the Paste cell action in Microsoft 365 Excel to copy a value from a cell and paste it to a specified cell. If there is a value in the destination cell, this action will overwrite the value.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select either the **Active cell** or **Specific cell** option to specify the cell from which to copy the value. If you have selected the **Specific cell** option, specify the address of the cell in the **Cell name** field.
- Enter the destination cell address to paste the value. For example, B3.

Read cell format action in Microsoft 365 Excel

Use the Read cell format action to retrieve the format of an active or a specified cell (such as vertical or horizontal alignment and wrap text) and assign the output to a string variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.

- Select the **Active cell** or **Specific cell** option to specify the cell from which to read the format. If you have selected the **Specific cell** option, specify the address of the cell in the **Cell name** field.
- Select a String variable to store the cell format from the **Assign the output to variable** list.

Read cell formula action in Microsoft 365 Excel

Use the Read cell formula action to retrieve a formula from an active or a specific cell and assign the output to a string variable. This action returns a blank value if the specified cell does not contain a formula.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Select the **Active cell** or **Specific cell** option to specify the cell from which to read the formula. If you have selected the **Specific** option, specify the address of the cell in the field.
- Select a string variable to store the name of the formula from the **Assign the output to variable** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Set cell action in Microsoft 365 Excel

Use the Set cell action to set a value in an active or a specific cell of an Excel spreadsheet or a CSV file. You can also use this action to set a formula.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Select the **Active cell** or **Specific cell** option to specify the cell in which to set the value. If you have selected the **Specific cell** option, specify the address of the cell in the field.

Note: You can enter a cell range in the **Specific cell** field to set a particular value in all the cells of the range. For example, to set a value of 5 on all cells in the second row and from the first through third column, enter **A2 : C2**.

- Enter the value to set in the **Cell value** field.

Set cell color action in Microsoft 365 Excel

Use the Set cell color action to set a color to the background or text of an active cell or a Specific cell in a worksheet.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select the **Active cell**, **Specific cell**, or **Cell range** option to specify the cell in which to set the color. If you have selected the **Specific cell** option, specify the address of the cell in the **Cell name** field.
- Select the item to which you want to apply the color: **Cell** or **Text within cell**.

- Enter a cell color by name or code.

Use either the color name or the hex value. For a list of color names and corresponding hex values, see [Frequently used cell colors](#) on page 2718.

Set cell formula action in Microsoft 365 Excel

The set cell formula action enables you to set the formula of a specified cell in a worksheet.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select the **Active cell**, **Specific cell**, or **Multiple cell** option to specify the cell in which to set the formula. If you have selected the **Specific cell** option, specify the address of the cell in the **Cell name** field. For the multiple cell option, specify a cell range.
- Enter the value to set in the **Cell formula** field, without an "=".

Column/Row operations in Microsoft 365 Excel

The Microsoft 365 Excel package contains actions that you can use to automate tasks related to column and row operations such as autofit, delete, insert, and read.

The Microsoft 365 Excel package includes the following actions:

Actions	Description
Autofit columns	See Autofit columns action in Microsoft 365 Excel on page 2724.
Autofit rows	See Autofit rows action in Microsoft 365 Excel on page 2724.
Delete row/column	See Using Delete action for rows or columns on page 2724.
Get row count	See Get row count action in Microsoft 365 Excel on page 2725.
Insert row/column	See Using Insert action for rows or columns on page 2725.
Read column	See Read column action in Microsoft 365 Excel on page 2725.
Read row	See Read row action in Microsoft 365 Excel on page 2726.

Autofit columns action in Microsoft 365 Excel

Use the Autofit columns action in the Microsoft 365 Excel package to adjust (automatically fit) the width of columns in a worksheet in a specified session.

Settings

Enter the name of the session used to open the workbook with the **Open** .

Autofit rows action in Microsoft 365 Excel

Use the Autofit rows action in the Microsoft 365 Excel package to adjust (automatically fit) the height of the rows in a worksheet in a specified session.

Settings

Enter the name of the session used to open the workbook with the **Open** .

Using Delete action for rows or columns

Use the **Delete** action to remove rows or columns from the current worksheet.

To delete rows or columns in a worksheet, do the following:

1. Double-click or drag **Office 365 Excel > Delete**.
2. Enter the name of the session used to open the workbook with the **Open** .
3. Select one of the following:
 - Row operations
 - a) Select the **Delete Row(s) at** option to delete all of the cells in a specific row. Specify the row number to delete in the field. For example, to delete the tenth row in the worksheet, enter 10 in the field.
 - b) Select the **Delete Row(s) by** option to delete all of the cells in either:
 - the row of the active cell.
 - a specific range of cells. Specify the range to delete. For example, to delete the first five rows, enter 1 : 5 in the field.
 - Column operations
 - a) Select the **Delete Column(s) at** option to delete all of the cells in a specific column. Specify the address of the column to delete in the field. For example, to delete column 'D' in the worksheet, enter D in the field.
 - b) Select the **Delete Columns(s) by** option to delete all of the cells in either:
 - the column of the active cell.
 - a specific range of cells. Specify the range to delete. For example, to delete the first five columns, enter A : E in the field.
4. Click **Save**.

Get row count action in Microsoft 365 Excel

Use the Get row count action in the Microsoft 365 Excel package to retrieve the number of rows that contain data in a worksheet.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Assign the output value to a Number variable.

To convert the variable to a String variable, use the **Number > To string** action. For more information, see [To string action in Number](#) on page 2699.

Using Insert action for rows or columns

Use the **Insert** action to create rows or columns in the current worksheet.

To insert or delete rows or columns in a worksheet, do the following:

1. Double-click or drag **Office 365 Excel > Insert**.
2. Enter the name of the session used to open the workbook with the **Open**.
3. Select one of the following:
 - Row operations
 - a) Select the **Insert Row(s) at** option to insert a row and specify the location where to insert the row in the field. For example, to insert a row of cells in the tenth row in the worksheet, enter 10 in the field.
 - b) Select the **Insert Row(s) by** option to insert all of the cells in either:
 - the row of the active cell.
 - a specific range of cells. Specify the range where to insert the row. For example, to insert a row of cells in the first five rows in the worksheet, enter 1 : 5 in the field.
 - Column operations
 - a) Select the **Insert Column(s) at** option to insert a column and specify the location where to insert the row in the field. For example, to insert a column of cells in column 'D' in the worksheet, enter D in the field.
 - b) Select the **Insert Columns(s) by** option to insert all of the cells in either:
 - the column of the active cell.
 - a specific range of cells. Specify the range to insert the column. For example, to insert a row of cells in the first five columns, enter A : E in the field.
4. Click **Save**.

Read column action in Microsoft 365 Excel

Use the Read column action in the Microsoft 365 Excel package to extract data from a column and store it in a List variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select the cell option as **Active cell** or **Specific cell** to specify the starting point.
- You can also select the **Read full column** option to extract data for the entire column.
- Assign the output value to a List variable.

Read row action in Microsoft 365 Excel

Use the Read row action in the Microsoft 365 Excel package to extract data from a row and store it in a variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select the cell option as **Active cell** or **Specific cell** to specify the starting point.
- You can also select the **Read full row** option to extract data for the entire row.
- Assign the output to a variable: Multiple variables or a Record variable.

Table operations in Microsoft 365 Excel

The Microsoft 365 Excel package contains various actions that you can use to automate tasks related to the table operations such as create, delete, filter, get properties, rename, and sort.

The Microsoft 365 Excel package includes the following actions:

Actions	Description
Create table	See Create table action in Microsoft 365 Excel on page 2726.
Delete table	See Delete table action in Microsoft 365 Excel on page 2727.
Get table column	See Get table column action in Microsoft 365 Excel on page 2727.
Get table names	See Get table names action in Microsoft 365 Excel on page 2727.
Get table row	See Get table row action in Microsoft 365 Excel on page 2727.
Get table row count	See Get table row count action in Microsoft 365 Excel on page 2728.
Rename table	See Rename table action in Microsoft 365 Excel on page 2728.

Create table action in Microsoft 365 Excel

The Create table action in the Microsoft 365 Excel package enables you to create a new table in the specified table range.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter the table name.
- Enter the cell range in which to create the table. For example, A1:D4.
- Optional: Select the **Table has headers** option to establish the first row as the header row.

Delete table action in Microsoft 365 Excel

The Delete table action in the Microsoft 365 Excel package enables you to delete a table in the active worksheet.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter the table name that has to be deleted.

Get table column action in Microsoft 365 Excel

Use the Get table column action in the Microsoft 365 Excel package to retrieve the column values of a specified table and column index, and assign the values to a List variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter the table name.
- Enter the column index. For example, enter 5 to indicate the fifth column from the left.
- Select a List variable to store the values.

Get table names action in Microsoft 365 Excel

The Get table names action in Microsoft 365 Excel enables you to retrieve the names of all the tables in a workbook and assign them to a List variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Optional: Select whether to specify a sheet either by index or name.
- Select a List variable to store the values.

Get table row action in Microsoft 365 Excel

The Get table row action in Microsoft 365 Excel enables you to retrieve the row values of a specified table and row index, and assign the values to a variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter the table name.
- Enter the row index. For example, enter 5 to indicate the fifth row from the top.
- Assign the output to a variable: Multiple variables or a Record variable.

Get table row count action in Microsoft 365 Excel

The Get table row count action in Microsoft 365 Excel enables you to retrieve the row count of a specified table and assign the values to a number variable.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter the table name.
- Select a Number type variable to store the values.
To convert the variable to a String variable, use the **Number > To string** action. For more information, see [To string action in Number](#) on page 2699 .

Rename table action in Microsoft 365 Excel

The Rename table action in Microsoft 365 Excel enables you to rename a table.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter the current or existing table name.
- Enter a new table name.

Workbook operations in Microsoft 365 Excel

The Microsoft 365 Excel package contains actions that enable you to automate opening, closing, or creating a new workbook.

The Microsoft 365 Excel package includes the following actions:

Actions	Description
Close	See Close action .
Create workbook	See Create workbook action .
Open	See Using the Open action on page 2729.

Close action in Microsoft 365 Excel

Use the Close action in Microsoft 365 Excel package to close a workbook.

Settings

Enter the name of the session used to open the workbook with the **Open** .

Create workbook action in Microsoft 365 Excel

Use the Create workbook action in Microsoft 365 Excel package when you want to create a new workbook.

Settings

- Enter Enter the name of the session used to open the workbook with the **Open** .
- Provide a **File Path** containing the new workbook name with one of the following extensions: .xls, .xlsm, .xlsx.

Either enter the file path or select a String variable. For example, to perform this action on a file named SalesReport.xlsx, located in the Accounts folder, enter `Accounts/SalesReport.xlsx`.

Using the Open action

Use this action to open a workbook. Insert this action at the start of your automation sequences.

To open a workbook, do the following:

1. Double-click or drag the **Open** action.
2. Provide the username either by selecting a Credential variable or entering an unencrypted value.
3. Enter a **Session name**.
Use this same session name in subsequent actions to associate them with this workbook.
4. Enter the **File Path** or insert a file variable.
For example, to perform this action on a file named SalesReport.xlsx, located in the Accounts folder, enter the file name `SalesReport.xlsx`.

Note: Ensure that the Microsoft Excel file is placed in the **My Files** folder in OneDrive.

5. If the sheet contains a header row, mark the **Sheet contains header** option.
6. Click **Save**.

Worksheet operations in Microsoft 365 Excel

The Microsoft 365 Excel package contains actions that you can use to automate tasks related to worksheet operations, such as delete, find, get worksheet names, hide, retrieve worksheet count, and show.

The Microsoft 365 Excel package includes the following actions:

Actions	Description
Copy worksheet	See Using the Copy worksheet action on page 2730.

Actions	Description
Create sheet	See Create sheet action in Microsoft 365 Excel on page 2731.
Delete worksheet	See Delete worksheet action in Microsoft 365 Excel on page 2731.
Get current worksheet name	See Get current worksheet name action in Microsoft 365 Excel on page 2731.
Get worksheet names	See Get worksheet names action in Microsoft 365 Excel on page 2731.
Hide worksheet	See Hide worksheet action in Microsoft 365 Excel on page 2732.
Rename worksheet	See Rename worksheet action in Microsoft 365 Excel on page 2732.
Retrieve sheet count	See Retrieve sheet count action in Microsoft 365 Excel on page 2732.
Show worksheet	See Show worksheet action in Microsoft 365 Excel on page 2733.
Switch to sheet	See Switch to sheet action in Microsoft 365 Excel on page 2733.

Using the Copy worksheet action

Use the **Copy worksheet** action to copy values of a worksheet from one worksheet to another. This action overwrites any existing values. To move values from one worksheet to another without overwriting existing values, use the **Append worksheet** action.

Open the workbook(s) containing the source and target worksheets. See [Using the Open action](#) on page 2729.

Note: This action identifies the destination and source workbooks by the session names used to open them. If opening two workbooks, enter a session name for the source workbook that is different than the one used to open the destination workbook.

To copy the values of a worksheet into another, do the following:

1. Double-click or drag the **Copy worksheet** action.
2. Enter the name of the session that you used to open the destination workbook in the **Open** action.
3. If the workbook contains more than one worksheet, mark the **Specific Sheet** option, then enter the index number or name of the source worksheet.
 - The index number represents the position of the worksheet in the workbook. For example, to perform an operation on the worksheet at the third position in the workbook, enter 3 in the field.
 - The sheet name field is case insensitive.
4. Enter the name of the session that you used to open the source workbook in the **Open** action.

5. If the workbook contains more than one worksheet, mark the **Specific Sheet** option, then enter the index number or name of the destination worksheet.
6. Click **Save**.

Create sheet action in Microsoft 365 Excel

The **Create sheet** action in the Microsoft 365 Excel package enables you to add an empty sheet in the current workbook.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter a **Worksheet name** of up to 31 characters. The name cannot contain the following characters: \ / ? * []

Delete worksheet action in Microsoft 365 Excel

The **Delete worksheet** action in the Microsoft 365 Excel package enables you to delete a spreadsheet from the current workbook.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Specify either an index number in the **Sheet by Index** field or a name in the **Sheet by Name** field for the worksheet. The index number is the number assigned to a worksheet. For example, if you want to perform an operation on the worksheet at the third position in the workbook, enter 3 in the field.

Note: You can delete a worksheet only if the workbook contains more than one worksheet.

Get current worksheet name action in Microsoft 365 Excel

The **Get current worksheet name** action in the Microsoft 365 Excel package enables you to retrieve the name of the currently active worksheet.

Settings

- Enter the name of the session used to open the workbook with the **Open** .
- Select a string variable that you want to use to store the name of the worksheet from the **Assign the output to variable** list. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Get worksheet names action in Microsoft 365 Excel

The **Get worksheet names** action in the Microsoft 365 Excel package enables you to retrieve the names of all the worksheets in the workbook.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Select a list variable to store the worksheet names from the **Assign the output to variable** list.

Hide worksheet action in Microsoft 365 Excel

The **Hide worksheet** action in the Microsoft 365 Excel package enables you to hide a worksheet from the current workbook.

Settings

- Specify the name of the worksheet to hide in the **Enter worksheet name to hide** field.

Note: You can hide a worksheet only if the workbook contains more than one worksheet.

- Enter the name of the session used to open the workbook with the **Open** .

Rename worksheet action in Microsoft 365 Excel

The **Rename worksheet** action in the Microsoft 365 Excel package enables you to rename a worksheet in the current workbook.

Settings

- Specify the index number or name of the worksheet to rename in the **Sheet by Index** or **Sheet by Name** field.

The index number is the number assigned to a worksheet. For example, if you want to perform an operation on the worksheet at the third position in the workbook, enter 3 in the field.

Note: You cannot rename the worksheet if a worksheet with the same name already exists in the workbook.

- Enter the new worksheet name that is under 31 characters.
- Enter the name of the session used to open the workbook with the **Open** .

Retrieve sheet count action in Microsoft 365 Excel

The **Retrieve sheet count** action in the Microsoft 365 Excel package enables you to get the number of sheets available in the current workbook and stores it in a number variable.

Settings

- Select the appropriate option to specify whether to include the hidden worksheet or not and assign the count to a variable.
- Enter the name of the session used to open the workbook with the **Open** .
- Select a number variable that you want to use to store the name of the worksheet from the **Select the variable to assign to** list. The shows a descriptive default variable name. If you

create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Show worksheet action in Microsoft 365 Excel

The **Show worksheet** action in the Microsoft 365 Excel package enables you to show the hidden worksheet.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Enter the **Worksheet name**.

Switch to sheet action in Microsoft 365 Excel

The **Switch to sheet** action in the Microsoft 365 Excel package enables you to activate a particular sheet in a Microsoft Excel file.

Settings

- Enter the name of the session used to open the workbook with the **Open** action.
- Specify whether to activate the **Sheet by Index** (numerical value) or **Sheet by Name**.

Microsoft 365 OneDrive package

The Microsoft 365 OneDrive package contains actions that enable you to automate many of the repetitive tasks in Microsoft cloud storage.

How to use the actions in the Microsoft 365 OneDrive package

Note: Microsoft has deprecated EWS API for Exchange Online and has recommended users to move to Graph API. Starting from Automation 360 v.29, Office 365 OneDrive package is called Microsoft 365 OneDrive package. Although the package name has changed, the functionality remains the same. So your existing bots from previous releases will continue to work as expected after an update to Automation 360 v.29.

Perform the following actions within the **One Drive** package as part of using the set of available actions:

1. Use the **Connect** action to establish a connection to the Microsoft 365 server.
See [Using Connect action in Microsoft 365 Calendar package](#) on page 2709.

Note: Microsoft 365 packages do not currently support Multi-Factor Authentication or Single Sign-on.

2. Use a combination of actions available in this package to automate tasks.

Note: To use actions from other Microsoft 365 packages, establish a connection using the **Connect** action from that package.

3. Use the **Disconnect** action to terminate the connection.

For an example on how to setup and connect to the Microsoft 365 OneDrive package, see [Setup Azure App to connect using Microsoft OneDrive package \(A-People login required\)](#).

Actions in the Microsoft 365 OneDrive package

Use the actions in the Microsoft 365 OneDrive package to perform an operation on a single file or folder. To perform the operation on every file in a folder, use that action in a loop. See [Using the One Drive actions in a loop](#) on page 2740.

Note: Automation 360 supports the shared drive. To use shared drive items such as a file or folder, ensure that you provide the link and name of that file or folder.

The Microsoft 365 OneDrive package includes the following actions:

Action	Description
Check permission	See Check permission action on page 2735.
Connect	Establishes a connection with the Office 365 server using your organization's client ID and tenant ID, and user credentials. See Using Connect action in Microsoft 365 Calendar package on page 2709.
Copy file or folder	See Copy file or folder action on page 2735.
Create folder	See Create folder action on page 2736.
Delete file or folder	See Delete file or folder action on page 2736
Disconnect	See Disconnect action for Office 365 packages on page 2713.
Download file	See Download file action on page 2737.
Export as PDF	See Export to PDF action on page 2737.
Find files and folders	See Find files and folders action on page 2738.
Get file or folder information	See Get file or folder information action on page 2738.
Move file or folder	See Move file or folder action on page 2739.
Rename file or folder	See Rename file or folder action on page 2739.

Action	Description
Restore last version	See Restore last version action on page 2739.
Upload file	See Upload file action on page 2740.

[Microsoft 365 OneDrive package updates](#) on page 872

Review the updates in released versions of the Microsoft 365 OneDrive package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Check permission action

The **Check permission** action in the Microsoft 365 OneDrive package checks for read and write permission for a file or folder in your OneDrive.

Settings

- Enter the Microsoft 365 user session that you provided in the **Connect** action.
- Use the **Check Permission for** field to select one of the following options:
 - **File name on OneDrive (including path & extension)**: to enter the file name on OneDrive for which the permissions must be verified.
 - **Folder name on OneDrive (including path)**: to enter a folder name on OneDrive where the permissions must be verified.

(Optional) For the above options, click the **Insert a value** icon to select an existing variable.

- Select one of the following options in the **Check permission type** field to specify the permission type to verify:
 - **Read**
 - **Read & Write**
- Use the **Assign output status to variable** drop-down to select a predefined Boolean type variable to hold the output during bot runtime.

(Optional) Click the **Create variable** icon on the right for a new variable. The Boolean type variable will provide a true (user has permission) or false (user does not have permission) response.

Copy file or folder action

The Copy file or folder action in the Microsoft 365 OneDrive package duplicates a file or folder from one folder to another in your OneDrive.

Settings

- Enter the user session that you provided in the **Connect** .

- Select whether to copy a file or folder.
- Provide the source and destination file/folder names and paths or file/folder link.

To obtain the file or folder link, copy the link generated from [Share OneDrive files and folders](#)

For example, to perform this action on a file named SalesReport.xlsx, located in the Accounts folder, enter `/Accounts/SalesReport.xlsx`.

Note: The forward slash that indicates that a file or folder is located in the root directory is optional.

- Optional: If there is file or folder with the same name in the destination folder, select the **Override existing file/folder** option which replaces the existing file or folder with the one being copied.

Create folder action

The Create folder action in the Microsoft 365 OneDrive package creates a new folder in a specific directory in your OneDrive.

Settings

- Enter the user session that you provided in the **Connect** .
- Enter the parent folder name and path, or folder link.

To obtain the folder link, copy the link generated from [Share OneDrive files and folders](#)

For example, to perform this action on a folder named Q1, located in the Survey Results folder, enter `/Survey Results/Q1`.

- Enter the new folder name.

Delete file or folder action

The Delete file or folder action in the Microsoft 365 OneDrive package removes a file or folder from a specific directory in your OneDrive.

Settings

- Enter the user session that you provided in the **Connect** .
- Select whether to delete a file or folder.
- Provide the name and path, or file or folder link.

To obtain the file or folder link, copy the link generated from

For example, to perform this on a file named SalesReport.xlsx, located in the Accounts folder, enter `/Accounts/SalesReport.xlsx`.

Note: The forward slash that indicates that a file or folder is located in the root directory is optional.

Download file action

The Download file action in the Microsoft 365 OneDrive package downloads a file from a specific directory in your OneDrive.

Settings

- Enter the user session that you provided in the **Connect** .
- Provide the file name and path, or file link.

To obtain the file link, copy the link generated from [Share OneDrive files and folders](#)

For example, to perform this on a file named SalesReport.xlsx, located in the Accounts folder, enter `/Accounts/SalesReport.xlsx`.

Note: The forward slash that indicates that a file or folder is located in the root directory is optional.

- Enter the destination folder path on the local device.
- Optional: If there is file or folder with the same name in the destination folder, select the **Override existing file/folder** option which replaces the existing file or folder with the one being copied.

Export to PDF action

The Export to PDF action in the Microsoft 365 OneDrive package exports an existing file in your OneDrive to a PDF on your device. This action supports the following file extensions: doc, docx, oentry, odp, pps, ppt, pptx, tf, xls, and xlsx.

Settings

- Enter the user session that you provided in the **Connect** .
- Provide the file name and path, or file link. Either enter the values or insert a predefined string variable.

To obtain the file link, copy the link generated from [Share OneDrive files and folders](#)

For example, to perform this on a file named SalesReport.xlsx, located in the Accounts folder, enter `/Accounts/SalesReport.xlsx`.

Note: The forward slash that indicates that a file or folder is located in the root directory is optional.

- Enter the export folder name and path or select a predefined string variable.
- Optional: If there is file or folder with the same name in the destination folder, select the **Override existing file/folder** option which replaces the existing file or folder with the one being copied.

Find files and folders action

The Find files and folders action in the Microsoft 365 OneDrive package returns a table of files and folders in a specific directory in your OneDrive.

Settings

- Enter the user session that you provided in the **Connect** .
- Provide directory details in the **Folder to search** field: enter the folder name and path, or folder link.

To obtain the folder link, copy the link generated from

For example, to perform this on a folder named Q1, located in the Survey Results folder, enter `/Survey Results/Q1`.

- Specify whether to search for **All items in folder** or a **Specific file (or folder)**.

Note: The **Drive Item Name** field accepts wildcard characters in the file name and extension. For example, to search for all documents with extension docx, enter `*.docx` in the **Specific file (or folder)** field.

- Assign the output to a table variable.

The variable will hold the following file or folder details: Name, ID, CreatedBy, CreationDate, LastModifiedBy, LastModificationDate, and ParentFolderPath.

Get file or folder information action

The Get file or folder information action in the Microsoft 365 OneDrive package retrieves information for a specific file or folder from OneDrive.

Settings

- Enter the user session that you provided in the **Connect** .
- Provide the file or folder name and path, or file/folder link.

To obtain the file or folder link, copy the link generated from

For example, to perform this on a file named SalesReport.xlsx, located in the Accounts folder, enter `/Accounts/SalesReport.xlsx`.

Note: The forward slash that indicates that a file or folder is located in the root directory is optional.

- Assign the output to a record variable.

The variable will hold the following file or folder details: Name, ID, CreatedBy, CreationDate, LastModifiedBy, LastModificationDate, and ParentFolderPath.

Move file or folder action

The Move file or folder action in the Microsoft 365 OneDrive package moves a file or folder from one folder to another in OneDrive.

Settings

- Enter the user session that you provided in the **Connect** .
- Select whether to move a file or folder.
- Provide the source and destination file or folder names and paths, or file/folder links.

To obtain the file or folder link, copy the link generated from

For example, to perform this on a file named SalesReport.xlsx, located in the Accounts folder, enter `/Accounts/SalesReport.xlsx`.

Note: The forward slash that indicates that a file or folder is located in the root directory is optional.

- Optional: If there is file or folder with the same name in the destination folder, select the **Override existing file/folder** option which replaces the existing file or folder with the one being copied.

Rename file or folder action

The Rename file or folder action in the Microsoft 365 OneDrive package renames a file or folder in a specific directory in OneDrive.

Settings

- Enter the user session that you provided in the **Connect** .
- Select whether to rename a file or folder.
- Provide the current and new file or folder names, or file/folder link.
- To obtain the file or folder link, copy the link generated from
- Optional: If there is file or folder with the same name in the destination folder, select the **Override existing file/folder** option which replaces the existing file or folder with the one being copied.

Restore last version action

The Restore last version action in the Microsoft 365 OneDrive package restores a file to the last version.

Settings

- Enter the user session that you provided in the **Connect** .
- Provide the file name and path, or file link.

To obtain the file or folder link, copy the link generated from

For example, to perform this on a file named SalesReport.xlsx, located in the Accounts folder, enter `/Accounts/SalesReport.xlsx`.

Note: The forward slash that indicates that a file or folder is located in the root directory is optional.

Upload file action

The Upload file action in the Microsoft 365 OneDrive package uploads a file to a specific directory in OneDrive.

Settings

- Enter the user session that you provided in the **Connect**.
- Provide the file name and path on the local directory.

For example, `D:/Mydata/HR/EmployeeSurvey.xlsx`.

- Provide the upload folder name and path, or folder link.

To obtain the folder link, copy the link generated from

For example, to perform this action on a folder named Q1, located in the Survey Results folder in home directory, enter `/Survey Results/Q1`

Note: You cannot provide the private folder path from one drive as it is not supported.

- Optional: If there is file or folder with the same name in the destination folder, select the **Override existing file/folder** option which replaces the existing file or folder with the one being copied.

Using the One Drive actions in a loop

Use the **Find files and folder** action to return a table of files and their properties inside of a specified folder, the **Loop** action to loop through each row in the table, and a **One Drive** action to perform an operation on every file in the table.

To perform an action on every file in a folder, do the following steps:

1. Double-click or drag **One Drive > Find files and folders**.
2. Provide your username with either a credential variable or an unencrypted value.
3. Enter the file path of the folder in which to perform the search.
4. Select the **All items in folder** option.
You can alternatively select **Specific file (or folder)** to limit the search to a specific folder on your OneDrive.
5. Select or create a table variable to hold the output.
The table variable holds information on files and folders in rows, under the following columns: name, id, createdBy, creationDate, lastModifiedBy, lastModificationDateTime, parentFolder, and Path.
6. Double-click or drag the **Loop** action.

7. Select the **For each row in table** iterator.
8. Select the table variable holding the output from step 5.
9. Select or create a record variable to temporarily hold each row.
Insert the action inside of the **Loop** container that you want to repeat on every file in the folder. This example uses the **Download file** action.
10. Double-click or drag **Outlook > Download file**.
11. Provide your username with either a credential variable or an unencrypted value.
12. Enter the following in the **File name including path** field, replacing the generic variable names with the names of the record variables from step 10:
`$RecordVariable [7] $/$RecordVariable [0] $`
13. Enter the path to the folder where to download the files.
14. Click **Save**.

Microsoft 365 Outlook package

The Microsoft 365 Outlook package enables you to automate Outlook emails over Microsoft Outlook server.

Before you start

Microsoft has deprecated EWS API for Exchange Online and has recommended users to move to Graph API.

See [Upcoming API Deprecations in Exchange Web Services for Exchange Online](#).

The Microsoft 365 Outlook package is based on the Graph API and can be used to automate email-related tasks for sending, receiving, and modifying emails and folders in Microsoft 365 Outlook.

Note: The integration of Graph API requires an administrator to grant access, after which you can configure an application access policy and limit the scope of application permissions. See [Configure application access policy](#).

Use this package in the following sequence:

- Use the **Connect** action to create a session.
- Use the various actions to automate tasks related to Microsoft 365 Outlook emails.
- Use the **Disconnect** action to terminate the connection to the Microsoft Outlook server.

Review the following table for important proxy considerations while using the Microsoft 365 Outlook package:

Proxy type	Description	Status
Authenticated	Same proxy settings for Control Room URL and Graph API Endpoints	Supported

Proxy type	Description	Status
	Different proxy credentials for Control Room URL and Graph API Endpoints	Not supported
	Bypass authenticated proxy for Control Room URL and authenticated proxy settings for Graph API Endpoints	Not supported
Unauthenticated	Same settings for Control Room URL and Graph API Endpoints	Supported
	Different proxy settings for Control Room URL and Graph API Endpoints	Supported
Combination of Authenticated and Unauthenticated	Authenticated proxy for Control Room URL and unauthenticated proxy settings for Graph API Endpoints	Supported
	Unauthenticated proxy for Control Room URL and authenticated proxy settings for Graph API Endpoints	Not supported
None	No Proxy found on the Bot Runner machine	Supported

Actions in the Microsoft 365 Outlook package

In the Actions palette on the Bot editor screen, double-click or drag any of the following actions in the Microsoft 365 Outlook package:

Action	Description
Change status	See Change status action in Microsoft 365 Outlook package on page 2743.
Check if folder exists	See Check if folder exists action in Microsoft 365 Outlook package on page 2744.
Connect	See Connect action in Microsoft 365 Outlook package on page 2744.
Delete	See Delete action in Microsoft 365 Outlook package on page 2752.
Delete all	See Delete all action in Microsoft 365 Outlook package on page 2752.
Disconnect	See Disconnect action in Microsoft 365 Outlook package on page 2753.

Action	Description
Forward	See Forward action in Microsoft 365 Outlook package on page 2753.
Move	See Move action in Microsoft 365 Outlook package on page 2755.
Move all	See Move all action in Microsoft 365 Outlook package on page 2755.
Reply	See Reply action in Microsoft 365 Outlook package on page 2756.
Reply all	See Reply all action in Microsoft 365 Outlook package on page 2758.
Save all attachments	See Save all attachments action in Microsoft 365 Outlook package on page 2760.
Save attachments	See Save attachments action in Microsoft 365 Outlook package on page 2761.
Save email	See Save email action in Microsoft 365 Outlook package on page 2761.
Send	See Send action in Microsoft 365 Outlook package on page 2761.

Related reference

[Microsoft 365 Outlook package updates](#) on page 873

Review the updates in released versions of Microsoft 365 Outlook package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Change status action in Microsoft 365 Outlook package

Use the **Change status** action in the Microsoft 365 Outlook package to change the status of emails. Ensure that you use this action within a **Loop** action to mark an email as Unread or Read in Microsoft 365 Outlook.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name:** to enter the session name that you have used in the **Connect** action.
 - **Variable:** to specify a session variable that can be used to share that session with other child bots.
- Use the **Change status to** field to select one of the following options:
 - **Unread:** to change the status of your email to Unread.
This is the default selection.
 - **Read:** to change the status of your email to Read.

Check if folder exists action in Microsoft 365 Outlook package

Use the **Check if folder exists** action in the Microsoft 365 Outlook package to verify if a specific folder is available in the Microsoft Outlook server.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name:** to enter the session name that you have used in the **Connect** action.
 - **Variable:** to specify a session variable that can be used to share that session with other child bots.
- In the **Folder name** field, enter the name of the folder you want to verify in your Microsoft 365 Outlook inbox.

Note: Review the following conditions for the **Folder name** field:

- Is not case sensitive.
- Regular expressions are not supported.
- Use \ (backslash) to specify a nested folder path.

For example, `inbox\folder1`

-
- In the **Save the outcome to variable** field, select a Boolean variable to store the output of the action.

Note: The Control Room shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication

Connect action in Microsoft 365 Outlook package

Use the **Connect** action in the Microsoft 365 Outlook package to establish a connection with a Microsoft 365 Outlook server. This is the first action you must use to automate Microsoft 365 Outlook related tasks.

OAuth 2.0 is used to connect to the Microsoft 365 Outlook server. Ensure that you configure OAuth 2.0 properties in the Microsoft Azure portal:

- For information on using the **Client credentials** authentication mode, see [Set up OAuth 2.0 using client credentials](#) on page 2746.
- For information on using the **Authorization code with PKCE** authentication mode, see [Set up OAuth 2.0 using authorization code with PKCE](#) on page 2749.

Settings

- Click the **Azure cloud** drop-down and select one of the following:
 - **Azure Global:** for Microsoft 365 Commercial version (`login.microsoftonline.com`)

- **Azure US GCC High**: for Microsoft 365 Government version (login.microsoftonline.us)
- Click the **OAuth2 Authentication mode** drop-down and select one of the following authentication modes:
 - **Client Credentials**

For more information, see [Microsoft identity platform and the OAuth 2.0 client credentials flow](#)

Use the following fields to enter the information that is provided for your account on your [Azure portal](#)

 - **Client ID**: enter the Office 365 client or insert it from the Credential Vault.
 - **Tenant ID**: enter the unique ID for your Office 365 subscription or insert it from the Credential Vault.
 - **Username**: enter the username that you want to use for accessing the Microsoft 365 Outlook server.
 - **Client secret**: enter your access token or insert it from the Credential Vault.

For all the above fields, you can use one of the following tabs to insert a value:

- **Credential**: to use a value in the Credential Vault that contains information about the Client ID/Client secret/ username/ password..
 - **Variable**: to use a user-defined variable that contains information about the Client ID/ Client secret/ username/ password.
 - **Insecure string**: to manually enter a value.
- **Authorization Code with PKCE**

For more information, see [Microsoft identity platform and OAuth 2.0 authorization code flow](#)

Use the following fields to enter the information that is provided for your [Azure portal](#):

- **Client ID**: enter the Office 365 client or insert it from the Credential Vault.
- **Tenant ID**: enter the unique ID for your Office 365 subscription or insert it from the Credential Vault.
- **Redirect URL**: enter the URL address.

The bot must run in an attended mode by providing a login form for the first time where you can enter your login credentials.

- **Username**: enter the email address of the mailbox you want to access within Microsoft 365 Outlook server.

OAuth2 credentials configured in the Microsoft Azure portal must be used to access this mailbox.

Note: If you have selected the **Authorization Code with PKCE** option, a browser is displayed that implies the connection to the Microsoft 365 Outlook server was established successfully. Ensure that you close this browser to continue.

- In the **Create Microsoft 365 Outlook session** field, use one of the following tabs for creating a session:
 - **Local session**: to specify a session name that can be used only in the current bot.

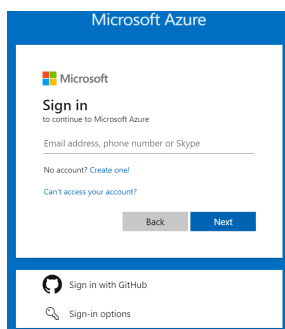

- **Global session:** to specify a session name that can be used across multiple bots, such as parent bots, child bots, and all other child bots of the parent bot.
- **Variable:** to specify a session variable that can be used to share that session with other child bots.

Set up OAuth 2.0 using client credentials

To set up OAuth 2.0 to use client credentials, you must register your Azure Active Directory application.

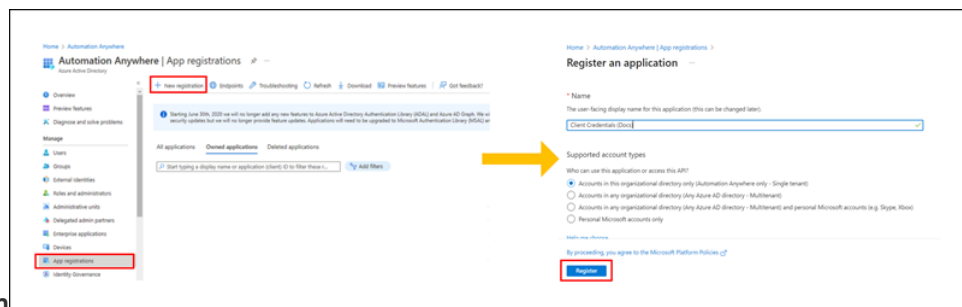

To register your Azure Active Directory application with the Microsoft identity platform, perform the following steps.

1. Log in to the Microsoft Azure portal.

Note: Enter your complete email address including the domain (for example, abc@domain.com).

2. On the **Home** page, click **View** under the **Manage Azure Active Directory** option.
3. On the **Overview** page, select **App registrations** from the **Manage** panel and then click **+ New**

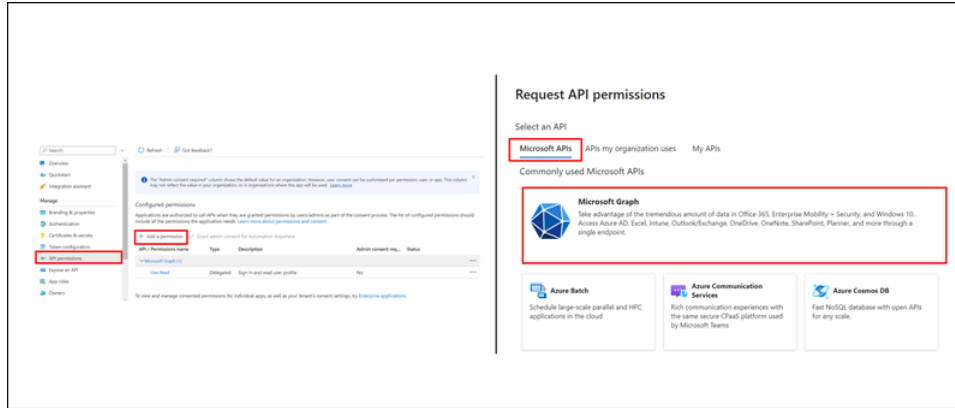

registration

4. On the **Register an application** page, enter the appropriate name in the **Name** field, then select the account type and click **Register**.

Note: You do not need to enter the Redirect URL because it is not required for the Client Credential flow.

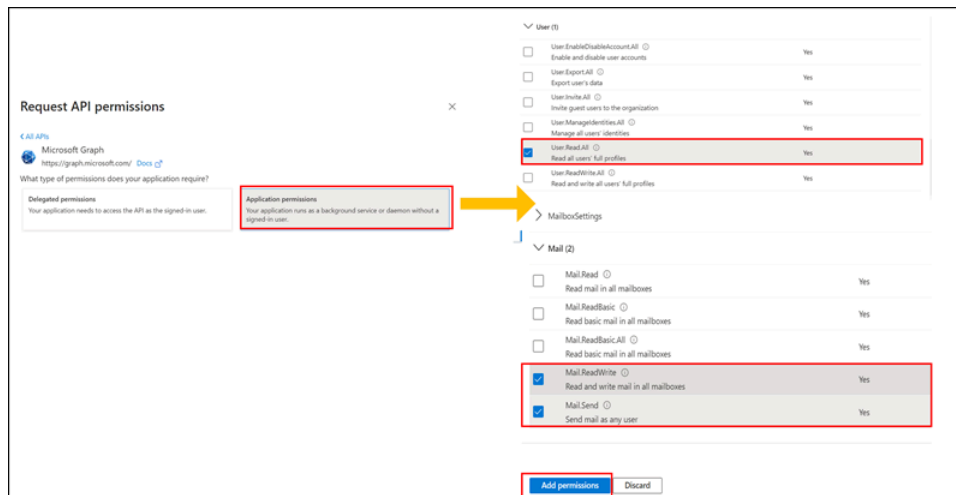

5. To set the API permission for the application to access the API resources, select the **API permissions** option under the **Manage** panel.
6. Click **+ Add a permission > Microsoft APIs** and select **Microsoft Graph**.

7. Select **Application permissions** and perform the following steps:
 - a) Search with **User** in the **Select permissions** search box and expand the **User** option.
 - b) Select the **User.Read.All** check box.

Note: Enabling the above option can grant access to all the mailboxes in your organization. Therefore it is important to impose access restrictions. Administrators can use `New-ApplicationAccessPolicy` PowerShell cmdlet to limit access to specific mailboxes. For more information, see [Limiting application permissions to specific Exchange Online mailboxes](#).

- c) Search with **Mail** in the **Select permissions** search box and expand the **Mail** option.
 - d) Select the **Mail.ReadWrite** and **Mail.Send** API permissions check boxes.
 - e) Click **Add permissions**.

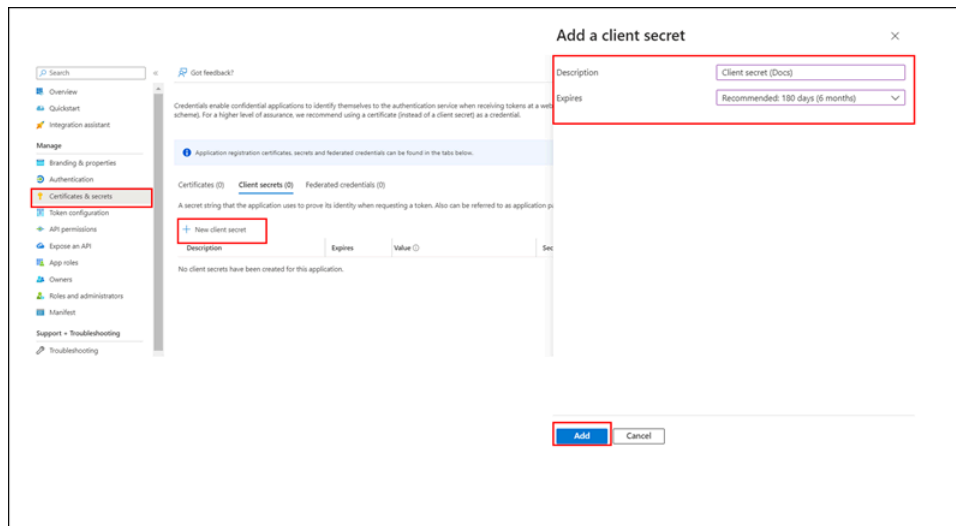

8. Click **Yes** to grant permission to use the API.

Ensure that the permissions are granted by an administrator or a user with administrator privileges, as shown in the

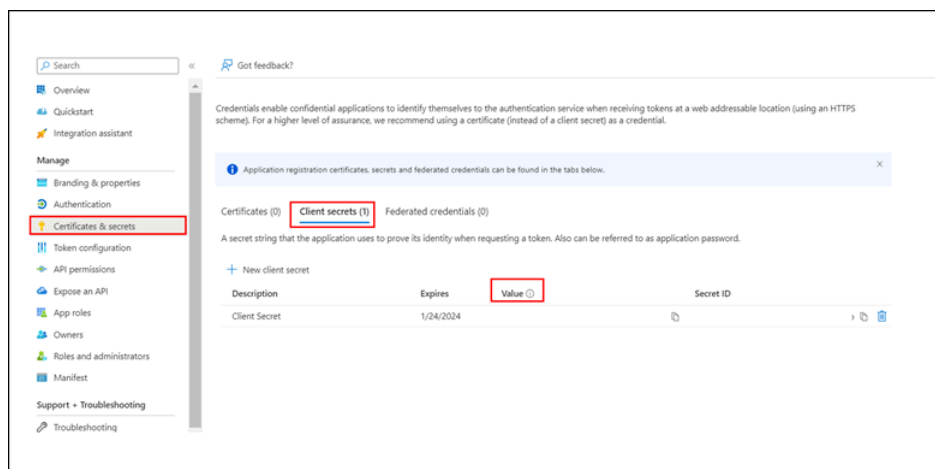

API / Permissions name	Type	Description	Admin consent req...	Status
+ Add a permission ✓ Grant admin consent for Automationanywhere Store				
Microsoft Graph (3)				
Mail.ReadWrite	Application	Read and write mail in all mailboxes	Yes	Granted for Automation... ***
Mail.Send	Application	Send mail as any user	Yes	Granted for Automation... ***
User.Read.All	Application	Read all users' full profiles	Yes	Granted for Automation... ***

following:

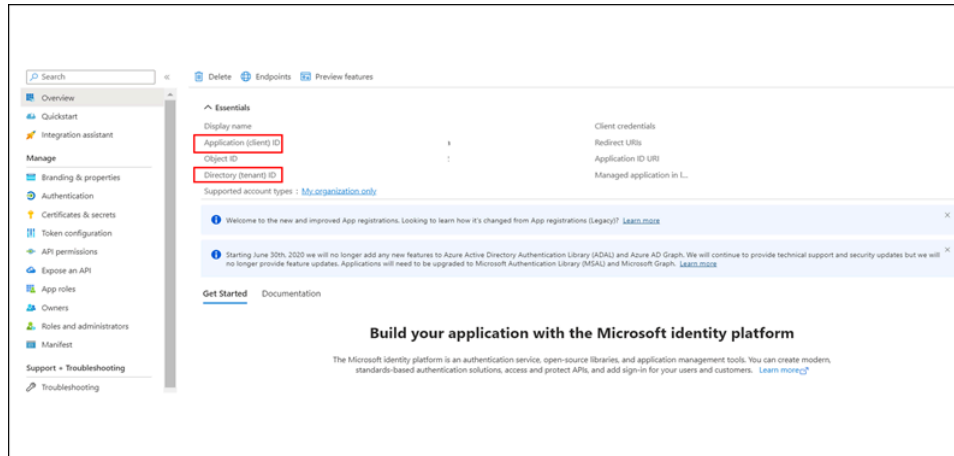

9. To create a client secret, click **Certificates and secrets** option under the **Manage** panel.
 - a) Click **+New client secret** to open the **Add a client secret** window.
 - b) Enter an appropriate description in the **Description** field and set the expiry duration.
 - c) Click **Add**.

- d) Copy and save the Client secret value to a safe location for your reference. We recommend that you do not share the value with anyone.

10. After an application is registered, the application is assigned with the **Client ID** and **Tenant ID**. You can click **Copy to clipboard** to copy the tenant and the client IDs.

You can use the Client ID, Tenant ID, and Client secret to establish a connection with a Microsoft 365 Outlook server.

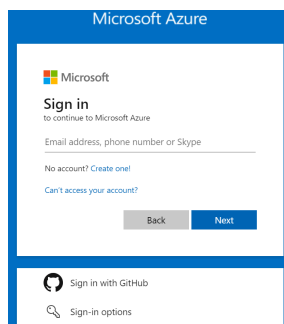

Note: If the mailbox is used inside a **Loop**, ensure that you register the user who is assigned to perform the automation. For more information, see .

Set up OAuth 2.0 using authorization code with PKCE

To set up OAuth 2.0 to use authorization code with PKCE, you must register your Azure Active Directory application.

To register your Azure Active Directory application with the Microsoft identity platform, perform the following steps:

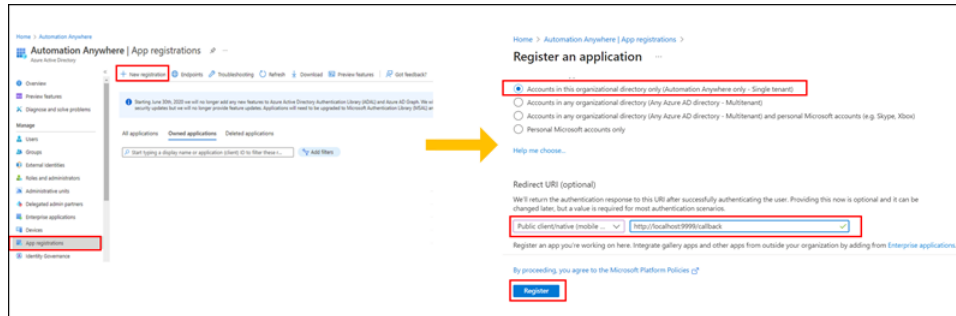

1. Log in to the Microsoft Azure portal.

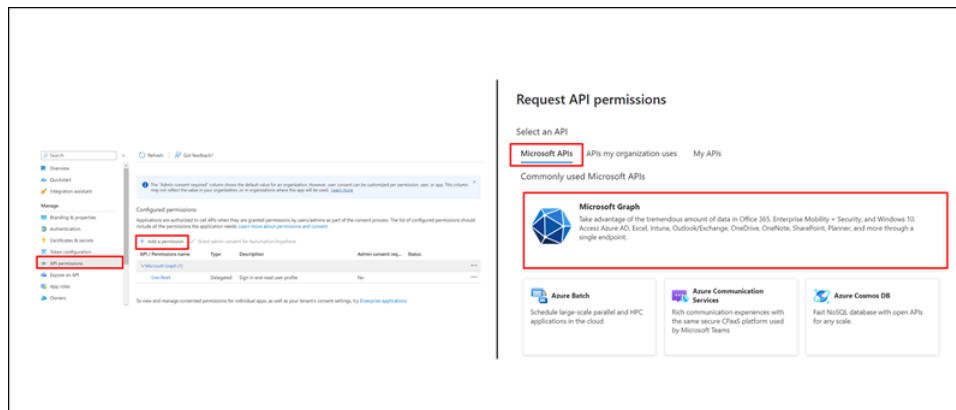

Note: Enter your complete email address including the domain (for example: abc@domain.com).

2. On the **Home** page, click **View** under the **Manage Azure Active Directory** option.
3. On the **Overview** page, select **App registrations** from the **Manage** panel and then click **+ New registration**.
4. On the **Register an application** page, enter the appropriate name in the **Name** field, then select the supported account type and configure the Redirect URI.
 - a) For the Redirect URI platform, select the **Public client/native (mobile & desktop)** option.
 - b) Set the Redirect URI to `http://localhost:9999/Callback`. Ensure that port 9999 is open or use any other open port.

c) Click **Register** to complete the initial app registration.

5. To set the API permission for the application to access the API resources, select the **API permissions** option under the **Manage** panel.
6. Click **+ Add a permission > Microsoft APIs** and select **Microsoft Graph**.

7. Select **Delegated permissions** and perform the following steps:

a) Select the following permissions:

- email
- offline_access
- openid
- profile

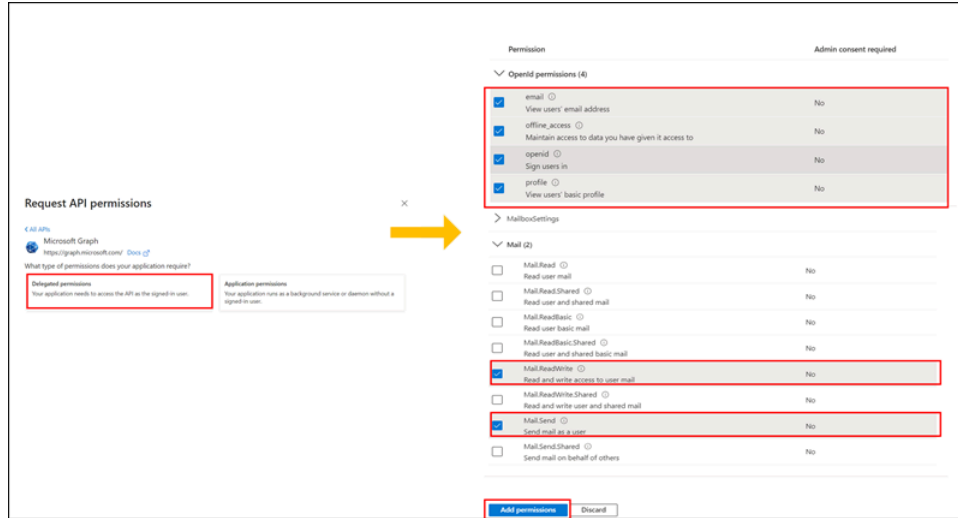

b) Search with **User** in the **Select permissions** search box and expand **User** option.

c) Select the **User.Read** check box.

Note: Administrators can use `New-ApplicationAccessPolicy PowerShell` cmdlet to limit access to specific mailboxes. For more information, see [Limiting application permissions to specific Exchange Online mailboxes](#).

d) Search with **Mail** in the **Select permissions** search box and expand the **Mail** option.

e) Select the **Mail.ReadWrite** and **Mail.Send** API permissions.

f) Click **Add permissions**.

g) Click **Yes** to grant permission to use the API.

Ensure that the permissions are granted by an administrator or a user with administrator privileges, as shown in the following:

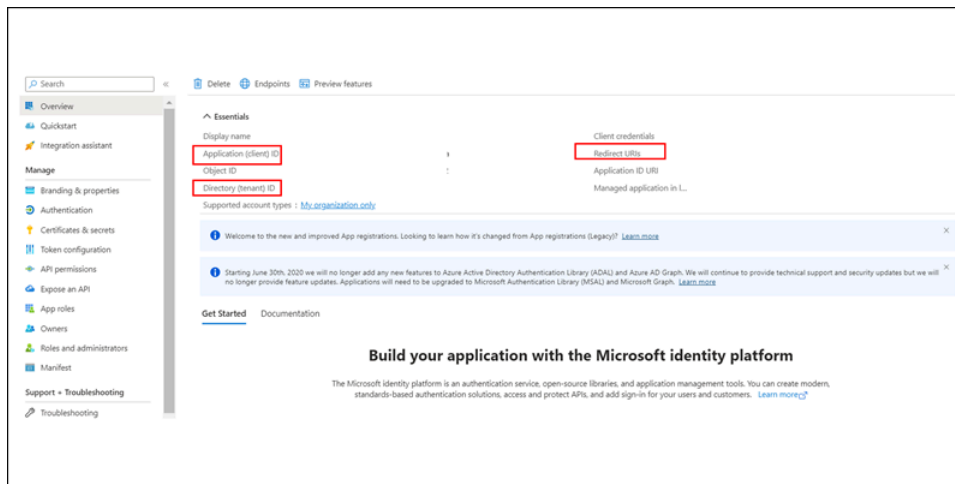

Configured permissions

Applications are authorized to call APIs when they are granted permissions by users/admins as part of the consent process. The list of configured permissions should include all the permissions the application needs. [Learn more about permissions and consent](#)

+ Add a permission ✓ Grant admin consent for Automationanywhere Store

API / Permissions name	Type	Description	Admin consent requ...	Status
▼ Microsoft Graph (7)				
email	Delegated	View users' email address	No	✓ Granted for Automation...
Mail.ReadWrite	Delegated	Read and write access to user mail	No	✓ Granted for Automation...
Mail.Send	Delegated	Send mail as a user	No	✓ Granted for Automation...
offline_access	Delegated	Maintain access to data you have given it access to	No	✓ Granted for Automation...
openid	Delegated	Sign users in	No	✓ Granted for Automation...
profile	Delegated	View users' basic profile	No	✓ Granted for Automation...
User.Read	Delegated	Sign in and read user profile	No	✓ Granted for Automation...

8. After an application is registered, the application is assigned with the **Client ID** and **Tenant ID**. You can click **Copy to clipboard** to copy the tenant and the client IDs.

You can use the Client ID, Tenant ID, and Client secret to establish a connection with a Microsoft 365 Outlook server.

Note: If the mailbox is used inside a **Loop**, ensure that you register the user who is assigned to perform the automation. For more information, see .

Delete action in Microsoft 365 Outlook package

Use the **Delete** action in the Microsoft 365 Outlook package to delete a specific email from your Microsoft 365 Outlook inbox. Ensure that you use this action within a **Loop** action.

Settings

In the **Microsoft 365 Outlook session** field, click one of the following tabs:

- **Session name:** to enter the session name that you have used in the **Connect** action.
- **Variable:** to specify a session variable that can be used to share that session with other child bots.

Delete all action in Microsoft 365 Outlook package

Use the **Delete all** action in the Microsoft 365 Outlook package to delete read, unread, or all emails from a specific folder in Microsoft 365 Outlook inbox.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name:** to enter the session name that you have used in the **Connect** action.
 - **Variable:** to specify a session variable that can be used to share that session with other child bots.
- Use the **From specific folders** field to specify the email folders from which you want to delete the emails.

For example, `Inbox/folder1`; `Inbox/folder2` or `Inbox/test*`.

Note: Microsoft 365 Outlook does not allow the use of wildcard entries (such as `*`) to run a search on folders. Ensure that you specify the folders individually in the **From specific folders** field.

- Use the **Status of email to delete** field to select one of the following type of emails you want to delete:
 - **Read:** emails that are in Read status.
 - **Unread:** emails that are in Unread status.
 - **Both:** emails in Read and Unread status.
- (Optional) Use the following fields to provide additional email filters:

- Enter keywords from the email subject line in the **When subject contains** field for the emails you want to delete.
 - This field is not case sensitive.
For example, the search results are the same for 'Sales information', 'sALes Information' or 'SALES INFORMATION'.
 - An empty space is treated as a character.
For example, salesinformation will display different results as compared to sales information.
 - Enclose the **Subject** link in double quotes ("") for an exact match.
For example, use "July sales information" in the **Subject** line.
- For more information, see [How subject filter works when moving emails](#) on page 2463.
- **From specific senders**: to specify the senders' email addresses.
For multiple senders, use semi-colon (;) to separate the email addresses.
- Use the **When the received date is on or after** field to select a date after which you received the emails.
Click the **Create variable** icon if there is no existing variable.
- Use the **When the received date is before** field to select a date before which you received the emails.
Optionally, you can also click the **Create variable** icon if there is no existing variable.

Disconnect action in Microsoft 365 Outlook package

Use the **Disconnect** action in the Microsoft 365 Outlook package to terminate an active connection with Microsoft 365 Outlook server.

Settings

In the **Microsoft 365 Outlook session** field, click one of the following tabs:

- **Session name**: to enter the session name that you have used in the **Connect** action.
- **Variable**: to specify a session variable that can be used to share that session with other child bots.

Forward action in Microsoft 365 Outlook package

Use the **Forward** action in the Microsoft 365 Outlook package to send emails and attachments to one or more recipients as plain text or HTML through Microsoft Outlook server. Ensure that you use this action within a **Loop** action.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name**: to enter the session name that you have used in the **Connect** action.

- **Variable:** to specify a session variable that can be used to share that session with other child bots.
- Enter the email addresses of the recipients in the **To** field.
- (Optional) Use the **Cc** and **Bcc** fields to enter email addresses of other recipients you want to mark a copy of the email.
- (Optional) In the **Attachment** field, select one of the following options to upload a file as an email attachment:

Option	Description
List	<ul style="list-style-type: none"> • Click Add to attach files. • Use one of the following tabs in the Value field to specify the location of the files that you want to attach: <ul style="list-style-type: none"> • Control Room file: To select an attachment that is available in the Control Room repository. • Desktop file: To select an attachment that is available on your device. <p>You can provide a combination of static path and string variable. To use it as a string variable, press F2 and select the string variable that stores the filepath. Or click Browse and select the filepath. After you have selected the filepath, you can insert a variable at any location to make it a dynamic filepath.. Enter the Variable name and paste the file path in the Default value field. Press F2 to insert the value of the filepath.</p> • Variable: To specify or select the file variable from the list..
Variable	Click the Insert a value icon to select an existing variable.

- Use the **Email body** field to select one of the following options for the email body:
 - **Plain text:** Use regular text in your email body, with no formatting effects, such as bold, italic, or underline, or special layout options.
 - **HTML design:** Use HTML script in your mail body when you want your content to be displayed in a certain layout every time. You can also include interactive elements, such as links.
 - **HTML code:** Use this option to create and customize your email layout and body. Use the editor toolbar to make various changes to your text, such as applying bold, italic, and other formatting effects, inserting links, and changing the font and size of the text. You can copy the content from the design editor and paste it in the **Message** field.
- Enter the content you want to send along with the email in the **Message** field.

Move action in Microsoft 365 Outlook package

Use the **Move** action in the Microsoft 365 Outlook package to move an email from one folder to another in the mailbox. Ensure that you use this action within a **Loop** action.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name:** to enter the session name that you have used in the **Connect** action.
 - **Variable:** to specify a session variable that can be used to share that session with other child bots.
- Use the **Destination folder path** field to enter the destination folder path that you want to move the email to.
For example, `Inbox/finance/April`.

Move all action in Microsoft 365 Outlook package

Use the **Move all** action in the Microsoft 365 Outlook package to move all your emails in Microsoft Outlook server from one folder to another.

The **Move all** action must be used outside a **Loop** action. For more information, see [Can Move all action be used within a loop? \(A-People login required\)](#).

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name:** to enter the session name that you have used in the **Connect** action.
 - **Variable:** to specify a session variable that can be used to share that session with other child bots.
- Use the **Destination folder path** in mailbox field to provide the folder location where you want to move all the emails.
- Use the **Status of email to move** field to select one of the following types of emails to move:
 - **Read:** emails that are in Read status.
 - **Unread:** emails that are in Unread status.
 - **Both:** emails in Read and Unread status.
- Enter the folder path in the **From specific folders** field to specify the folder from where you want to move the emails.
For example, `Inbox/project1`.
- Enter keywords from the email subject line in the **When subject contains** field for the emails you want to move.
 - This field is not case sensitive.
For example, the search results are the same for `Sales information`, `sALes Information` or `SALES INFORMATION`.

- An empty space is treated as a character.
For example, `salesinformation` will display different results as compared to 'sales information'.
- Enclose the **Subject** link in double quotes (") for an exact match.
For example, use "July sales information" in the Subject line.

For more information, see [How subject filter works when moving emails](#) on page 2463.

- Enter email addresses of specific senders in the **From specific senders** field.
For multiple senders, use semi-colon (;) to separate the email addresses.
- Use the **When the received date is on or after** field to select a date after which you received the emails.
Click the **Create variable** icon if there is no existing variable.
- Use the **When the received date is before** field to select a date before which you received the emails.
Click the **Create variable** icon if there is no existing variable.

Reply action in Microsoft 365 Outlook package

Use the **Reply** action in the Microsoft 365 Outlook package to send an email response without changing the subject line in the original email. Ensure that you use this action within a **Loop** action. This action does not include any files attached to the original email.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name**: to enter the session name that you have used in the **Connect** action.
 - **Variable**: to specify a session variable that can be used to share that session with other child bots.
- (Optional) Use the **Cc** and **Bcc** fields to enter the email address of additional recipients.
The **Cc** and **Bcc** are not case sensitive.
- (Optional) Use the **Attachment** field to select **List** or **Variable**.
The **Attachment** field enables you to specify if multiple files can be attached as a list or a variable must be created to hold the list values of the file object. Review the following table for more information:

Option	Description
List	<ul style="list-style-type: none"> • Select the attachment from a location: <ul style="list-style-type: none"> • Control Room file: To select an attachment that is available in the Control Room repository. • Desktop file: To select an attachment that is available on your device. <p>You can provide a combination of static path and string variable. To use it as a string variable, press F2 and select the string variable that stores the filepath. Or click Browse and select the filepath. After you have selected the filepath, you can insert a variable at any location to make it a dynamic filepath.. Enter the Variable name and paste the file path in the Default value field. Press F2 to insert the value of the filepath.</p> <ul style="list-style-type: none"> • Variable: To specify or select the file variable from the list.. <ul style="list-style-type: none"> • Specify the path that you want to attach in the Value field. Click Add to attach multiple files.
Variable	<p>Enables you to specify the list of file objects that contain the location of the attachments.</p> <p>Create a new variable of type List with subtype File, and add the filepath in the Default value field (optional). You can choose the file from the Desktop or Control room.</p>

- Use the **Email body** field to select one of the following format options for the body of the email:
 - **Plain text:** Use regular text in your email body, with no formatting effects, such as bold, italic, or underline, or special layout options.
 - **HTML design:** Use HTML script in your mail body when you want your content to be displayed in a certain layout every time. You can also include interactive elements, such as links.
 - **HTML code:** Use this option to create and customize your email layout and body. Use the editor toolbar to make various changes to your text, such as applying bold, italic, and other formatting effects, inserting links, and changing the font and size of the text. You can copy the content from the design editor and paste it in the **Message** field.

- Enter the content you want to send along with the email in the **Message** field.
The email is appended to the message that you have specified.

Reply all action in Microsoft 365 Outlook package

Use the **Reply all** action in the Microsoft 365 Outlook package to send an email response with the same or modified subject and include all the recipients of that email. Ensure that you use this action within a **Loop** action.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name**: to enter the session name that you have used in the **Connect** action.
 - **Variable**: to specify a session variable that can be used to share that session with other child bots.
- (Optional) Use the **Cc** and **Bcc** fields to enter the email address of additional recipients.
The **Cc** and **Bcc** are not case sensitive.
- (Optional) Select the **Exclude the sender of the email** check box to remove the email address of the sender.
- (Optional) Use the **Attachment** field to select **List** or **Variable**.

The **Attachment** field enables you to specify if multiple files can be attached as a list or a variable must be created to hold the list values of the file object. Review the following table for more information:

Option	Description
List	<ul style="list-style-type: none"> • Select the attachment from a location: <ul style="list-style-type: none"> • Control Room file: To select an attachment that is available in the Control Room repository. • Desktop file: To select an attachment that is available on your device. <p>You can provide a combination of static path and string variable. To use it as a string variable, press F2 and select the string variable that stores the filepath. Or click Browse and select the filepath. After you have selected the filepath, you can insert a variable at any location to make it a dynamic filepath.. Enter the Variable name and paste the file path in the Default value field. Press F2 to insert the value of the filepath.</p> <ul style="list-style-type: none"> • Variable: To specify or select the file variable from the list.. • Specify the path that you want to attach in the Value field. Click Add to attach multiple files.
Variable	Enables you to specify the list of file objects that contain the location of the attachments. Click the Insert a value icon to select an existing variable.

- Use the **Email body** field to select one of the following format options for the body of the email:
 - **Plain text:** Use regular text in your email body, with no formatting effects, such as bold, italic, or underline, or special layout options.
 - **HTML design:** Use HTML script in your mail body when you want your content to be displayed in a certain layout every time. You can also include interactive elements, such as links.
 - **HTML code:** Use this option to create and customize your email layout and body. Use the editor toolbar to make various changes to your text, such as applying bold, italic, and other formatting effects, inserting links, and changing the font and size of the text. You can copy the content from the design editor and paste it in the **Message** field.
 - Enter any content you want to send along with the email in the **Message** field.
- The email will be appended to the message you have specified.

Save all attachments action in Microsoft 365 Outlook package

Use the **Save all attachments** action in the Microsoft 365 Outlook package to save all the email attachments on Microsoft Outlook server to a specific folder.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name:** to enter the session name that you have used in the **Connect** action.
 - **Variable:** to specify a session variable that can be used to share that session with other child bots.
- Use the **Status of email** field to select one of the following type of emails from where you want to save the attachments:
 - **Read:** emails that are in Read status.
 - **Unread:** emails that are in Unread status.
 - **Both:** emails in Read and Unread status.

- Enter the folder path in the **From specific folders** field to specify the folder from where you want to save the attachments.

For example, `Inbox/project1`. Although multiple folder paths separated by semicolon are supported in this field, the regular expressions are not supported.

- (Optional) Enter keywords from the email subject line in the **When subject contains** field.

The **When subject contains** field is case sensitive. When you enter keyword within double quotes (""), the bot retrieves all the emails where the subject matches the text and the case
- (Optional) Enter email addresses of specific senders in the **From specific senders** field.
- (Optional) Use the **When the received date is on or after** field to select a date after which you received the emails.

Click the **Create variable** icon if there is no existing variable.

- (Optional) Use the **When the received date is before** field to select a date before which you received the emails.

Click the **Create variable** icon if there is no existing variable.

- In the **Save attachments to folder** field, enter the filepath of the folder where you want to save the email attachments.

You can also click the **Insert a value** icon to select a variable.

- (Optional) Clear the **Overwrite file(s)** check box if you do not want to overwrite any existing files in the folder.

The **Overwrite file(s)** option is enabled by default.

Save attachments action in Microsoft 365 Outlook package

Use the **Save attachment** action in the Microsoft 365 Outlook package to save attachments from a specific email to a folder. Ensure that you use this action within a **Loop** action.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name:** to enter the session name that you have used in the **Connect** action.
 - **Variable:** to specify a session variable that can be used to share that session with other child bots.
- In the **Save attachments to folder** field, enter the filepath of the folder where you want to save the email attachments.
- (Optional) Clear the **Overwrite file(s)** check box if you do not want to overwrite any existing files in the folder.

The **Overwrite file(s)** option is enabled by default.

Save email action in Microsoft 365 Outlook package

Use the **Save email** action in the Microsoft 365 Outlook package to save an email as an EML file to a folder. Ensure that you use this action within a **Loop** action.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - **Session name:** to enter the session name that you have used in the **Connect** action.
 - **Variable:** to specify a session variable that can be used to share that session with other child bots.
- Enter the location where you want to save the email in **Save emails to folder**.

The **Save emails to folder** is not case sensitive.
- (Optional) Clear the **Overwrite file(s)** check box if you do not want to overwrite any existing files in the folder.

The **Overwrite file(s)** option is enabled by default.

Send action in Microsoft 365 Outlook package

Use the **Send** action in the Microsoft 365 Outlook package to send an email to one or more recipients from Microsoft 365 Outlook, as plain text or HTML format.

The **Send** action enables you to attach multiple files of various formats to an email. There is no restriction on the type or size of file you can attach. However, restrictions implemented by the Microsoft exchange server you are using to send an email apply.

Note: Attachments sent as part of email automation are subject to the policies and rules set at the level of the proxy server, firewall, anti-virus, email server, customer environment, and so on.

Settings

- In the **Microsoft 365 Outlook session** field, click one of the following tabs:
 - Session name:** to enter the session name that you have used in the **Connect** action.
 - Variable:** to specify a session variable that can be used to share that session with other child bots.
- Enter the email addresses of the recipients in the **To** field.
- (Optional) Use the **Cc** and **Bcc** fields to enter email addresses of other recipients you want to mark a copy of the email.
- Enter the email subject in the **Subject** field.
- (Optional) In the **Attachment** field, select one of the following tabs to upload an file as an email attachment::

Option	Description
List	<ul style="list-style-type: none"> Click Add to attach files. Use one of the following tabs in the Value field to specify the location of the files that you want to attach: <ul style="list-style-type: none"> Control Room file: To select an attachment that is available in the Control Room repository. Desktop file: To select an attachment that is available on your device. <p>You can provide a combination of static path and string variable. To use it as a string variable, press F2 and select the string variable that stores the filepath. Or click Browse and select the filepath. After you have selected the filepath, you can insert a variable at any location to make it a dynamic filepath.. Enter the Variable name and paste the file path in the Default value field. Press F2 to insert the value of the filepath.</p> Variable: To specify or select the file variable from the list..
Variable	Click the Insert a value icon to select an existing variable.

- (Optional) Select the **Raise error if the attachments are missing (Desktop only)** check box if you want to be notified when you have not attached any files to your email.
- Use the **Email** field to select one of the following options for the email body:

- **Plain text:** Use regular text in your email body, with no formatting effects, such as bold, italic, or underline, or special layout options.
- **HTML design:** Use HTML script in your mail body when you want your content to be displayed in a certain layout every time. You can also include interactive elements, such as links.
- **HTML code:** Use this option to create and customize your email layout and body. Use the editor toolbar to make various changes to your text, such as applying bold, italic, and other formatting effects, inserting links, and changing the font and size of the text. You can copy the content from the design editor and paste it to other windows.
- (Optional) Enter the content you want to send along with the email in the **Message** field.

PDF package

Use the PDF package to automate various operations on a PDF file.

The PDF package enables you to perform the following tasks:

- Encrypt or decrypt a PDF file.
- Extract text from a PDF file.
- Convert a PDF file to an image.
- Merge several PDF files into a single file.
- Split a single PDF file into multiple files.

It is not necessary to have a PDF reader installed on your device.

Actions in the PDF package

The PDF package includes the following actions:

Note: The Extract field, Extract image, and Extract text actions in the PDF package are supported only for PDF files that are editable. These packages are not supported for scanned PDF documents that contain the PDF content as images.

Action	Description
Decrypt document	See Using the Decrypt document action on page 2768.
Encrypt document	See Using the Encrypt document action on page 2764.
Extract field	See Using the Extract field action on page 2765
Extract image	See Using the Extract image action on page 2767.
Extract text	See Using Extract text action from PDF on page 2766.
Get property	See Using the Get property action on page 2769
Merge documents	See Using the Merge documents action on page 2770.
Split document	See Using the Split document action on page 2771.

When an operation is performed on a PDF file, the file properties are stored in a dictionary variable. See [Using a dictionary variable for PDF properties](#) on page 2772.

Related reference

[PDF package updates](#) on page 881

Review the updates in released versions of the PDF package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using the Encrypt document action

Use the **Encrypt document** action to encrypt a PDF file.

To encrypt a PDF file, follow these steps:

1. In the **Actions** palette, double-click or drag the **Encrypt document** action from the PDF package.
2. In the **PDF path**, select one of the following options to specify the location of the PDF:
 - **Control Room file**: Enables you to select a PDF file that is available in a folder in the Control Room.
 - **Desktop profile**: Enables you to select a PDF file that is available on your device.
 - **Variable**: Enables you to specify the file variable that contains the location of the PDF file.
3. Optional: In the **User password** or **Owner password** field, enter a password to restrict access to the encrypted PDF file.
 - **User password**: Allow users to perform specific operations on the encrypted PDF file.
 - **Owner password**: Allow users to use a password to open the file.
4. In the **User Permissions to Apply** field, select the following operations:
 - **Print**: Allows users to print the document.
 - **Modify**: Allows users to edit the document.
 - **Copy**: Allows users to copy the document.
 - **Form Fill**: Allows users to fill a form in the document.
 - **Document Assembly**: Allows users to combine multiple PDF files, attach files, and so on.
 - **Annotation**: Allows users to apply annotations in the document.
 - **Accessibility**: Allows users to read text from the document using accessibility devices.
5. In the **Encryption level**, select the **RC4 40-bit**, **RC4 128-bit**, or **AES 128-bit** option to specify the encryption level.
6. In the **Save encrypted PDF as** field, specify a name and location for the encrypted file. You must include the .pdf extension in the name of the encrypted file. For example, if the file name is `June_Quarter_report`, the .pdf extension is `June_Quarter_report.pdf`.
7. Select the **Overwrite files with the same name** check box to overwrite existing files with the same name.

Note: If this option is not selected and the bot encounters a file with the same name at the specified location, the bot will fail.

8. Optional: From the **Assign PDF properties to a dictionary variable** list, select a dictionary variable to hold the file properties.

For more information, see [Using a dictionary variable for PDF properties](#) on page 2772.

9. Click **Save**.

Related tasks

[Using the Decrypt document action](#) on page 2768

Use the **Decrypt document** action to decrypt a PDF file that was previously encrypted using the **Encrypt document** action.

Using the Extract field action

Use the **Extract field** action to extract fields from a PDF and assign it to variables.

Important:

- When you extract fields from a PDF that contains 20 form fields, processing time might be 30 to 40 % longer than PDFs without form fields.
 - When you use this action to extract a radio button from a PDF file, the value generated might be -1 when no radio button is selected. Previously, when you did not select any radio button, the output was 0.
-

To extract fields from a PDF file, follow these steps:

1. In the **Actions** palette, double-click or drag the **Extract field** action from the **PDF** package.
2. In the **PDF path**, select one of the following options to specify the location of the PDF:
 - **Control Room file**: Enables you to select a PDF file that is available in a folder in the Control Room.
 - **Desktop profile**: Enables you to select a PDF file that is available on your device.
 - **Variable**: Enables you to specify the file variable that contains the location of the PDF file.
3. From the **File is protected** field, select **Yes** if the file is encrypted and provide the **User password** or **Owner password**.
4. Click **Open PDF viewer**.
5. In the **Select a PDF file** window, select a PDF file from Control Room file or Desktop file.
6. Optional: Enter the password.
7. Click **Load** to open the **PDF Viewer**.
In the **PDF Viewer** window, the PDF is opened with all the structured fields highlighted in purple dotted rectangles.
8. Select the rectangular area of the field to be extracted and click **Add field** to add the field and its value under the **Extract fields** table.
9. Optional: You can add an unstructured field that are not highlighted in the PDF. Select the **Draw a region** option available at the top of the PDF viewer and draw a rectangle box around the required region.

A red colored dotted rectangle is highlighted with an option **Add custom region**

10. Click **Add custom region** to view the captured coordinates in the **Custom region** window. Enter the **Key name** that can be used in the output variable.
11. Click **Close** to add the field in the **Extract fields** table.

The list of extracted fields appear under the **Extract fields** table on the right panel of **PDF viewer** window.

The extracted fields change to blue dotted rectangles in the PDF viewer. You can edit the extracted fields by selecting the blue rectangle around the field.

Use the vertical ellipse button next to the extracted field in the **Extract fields** table to **Edit**, **Move** or **Delete** the field.

12. Click **Close** to close the PDF viewer .
13. From the **Save the output to a variable** field, choose either a dictionary variable or multiple variables to hold the field values.
14. Click **Save**.

Using Extract text action from PDF

Extract text from a PDF file and save it as a text file by using the **Extract text** action.

Important:

- If the correct fonts are not embedded in the PDF file, the **Extract text** action does not extract the text correctly.
 - When you use this action to extract text from a PDF file, and if that text is a single line data but the PDF file has the same data in two lines, then the data might appear in two lines.
-

Note: When you extract fields from a PDF that contains 20 form fields, processing time might be 30 to 40 % longer than PDFs without form fields.

To extract text from a PDF file, perform the following steps:

1. In the **Actions** palette, double-click or drag the **Extract text** action from the **PDF** package.
 2. In the **PDF path**, select one of the following options to specify the location of the PDF:
 - **Control Room file:** Enables you to select a PDF file that is available in a folder in the Control Room.
 - **Desktop profile:** Enables you to select a PDF file that is available on your device.
 - **Variable:** Enables you to specify the file variable that contains the location of the PDF file.
 3. Optional: In the **User password** or **Owner password** field, enter a password to restrict access to the encrypted PDF file.
 - **User password:** Allow users to perform specific operations on the encrypted PDF file.
 - **Owner password:** Allow users to use a password to open the file.
 4. In the **Text type** field, select one of the following options:
 - **Plain text:** Extract the text and copy it to a text file.

This works similar to copying and pasting text from a PDF file to a text file.
 - **Structured text:** Preserve the original formatting of the text extracted from the PDF file.

You can select the **Reduce Data Loss** option to ensure that the complete text is extracted with minimal overlap of characters. With this functionality, the number of characters overlapped by other characters is reduced.
-

Note: When you select this option to extract text, the extracted text might contain extra space characters.

5. In the **Page range** field, select one of the following options:

- **All pages:** Enables you to save all the pages in the PDF file as an image.
 - **Pages:** Enables you to enter the page numbers of the pages that you want to save as an image.
6. In the **Export data to text file** field, specify a name and location for the text file.
-
- Note:** You must include the .txt extension in the name of the text file. For example, if the file name is `June_Quarter_report`, the .txt extension is `June_Quarter_report.txt`.
-
7. Select the **Overwrite files with the same name** check box to overwrite existing files with the same name.
-
- Note:** If this option is not selected and the bot encounters a file with the same name at the specified location, the bot will fail.
-
8. Optional: From the **Assign PDF properties to a dictionary variable** list, select a dictionary variable to hold the file properties.
For more information, see [Using a dictionary variable for PDF properties](#) on page 2772.
9. Click **Save**.

Using the Extract image action

Use the **Using Extract image** action to save a PDF file as an image.

To save a PDF file as an image, follow these steps:

1. In the **Actions** palette, double-click or drag the **Extract image** action from the **PDF** package.
2. In the **PDF path**, select one of the following options to specify the location of the PDF:
 - **Control Room file:** Enables you to select a PDF file that is available in a folder in the Control Room.
 - **Desktop profile:** Enables you to select a PDF file that is available on your device.
 - **Variable:** Enables you to specify the file variable that contains the location of the PDF file.
3. Optional: In the **User password** or **Owner password** field, enter a password to restrict access to the encrypted PDF file.
 - **User password:** Allow users to perform specific operations on the encrypted PDF file.
 - **Owner password:** Allow users to use a password to open the file.
4. In the **Page range** field, select one of the following options:
 - **All pages:** Enables you to save all the pages in the PDF file as an image.
 - **Pages:** Enables you to enter the page numbers of the pages that you want to save as an image.
5. In the **Type of image to be converted to** list, select one of the following options to specify the format:
 - **TIFF:** If you selected this option, select an option from the **TIFF compression type** list.
 - **NONE**
 - **LZE**
 - **RLE**
 - **CCITT Group 3**

- **CCITT Group 4**
 - **BMP**
 - **JPEG**: If you selected this option, in the **JPEG quality** field, enter a value (between 0 and 100) to specify the quality of the compressed image.
 - **GIF**
 - **PNG**
 - **WMF**
 - **EMF**
 - **EXIF**
6. In the **Folder path** field, specify the location.
 7. In the **File prefix** field, enter a value.
The image files are suffixed with index numbers. For example, if you have specified **Report** as the **File prefix**, the name of the image files will be **Report_1**, **Report_2**, and so on.
 8. Select the **Overwrite files with the same name** check box to overwrite existing files with the same name.

Note: If this option is not selected and the bot encounters a file with the same name at the specified location, the bot will fail.

9. In the **X Resolution (dpi)** and **Y Resolution (dpi)** fields, specify the resolution.
10. In the **Image output** field, choose **Color** or **Grayscale** to specify the image output type:
 - a) In the **Color property** list, select an option.
 - **True color (32 bits)**
 - **True color (24 bits)**
 - **High color (16 bits)**
 - **56 color (8 bits)**
 - **16 color (4 bits)**
 - **2 color (1 bit, black/white)**

Note: This option is available only with the **Color** image output type. Select this option only if **RLE**, **CCITT Group 3**, or **CCITT Group 4** compression type is selected for the **TIFF** image format.

11. Optional: From the **Assign PDF properties to a dictionary variable** list, select a dictionary variable to hold the file properties.
For more information, see [Using a dictionary variable for PDF properties](#) on page 2772.
12. Click **Save**.

Using the Decrypt document action

Use the **Decrypt document** action to decrypt a PDF file that was previously encrypted using the **Encrypt document** action.

To decrypt an encrypted PDF file, follow these steps:

1. In the **Actions** palette, double-click or drag the **Decrypt document** action from the **PDF** package.

2. In the **PDF path**, select one of the following options to specify the location of the PDF:
 - **Control Room file**: Enables you to select a PDF file that is available in a folder in the Control Room.
 - **Desktop profile**: Enables you to select a PDF file that is available on your device.
 - **Variable**: Enables you to specify the file variable that contains the location of the PDF file.
3. Optional: In the **User/Owner password** field, enter a password to restrict access to the decrypted PDF file.
4. In the **Save the decrypted PDF file as** field, specify a name and location for the decrypted file. You must include the .pdf extension in the name of the decrypted file. For example, if the file name is `June_Quarter_report`, the .pdf extension is `June_Quarter_report.pdf`.
5. Select the **Overwrite files with the same name** check box to overwrite existing files with the same name.

Note: If this option is not selected and the bot encounters a file with the same name at the specified location, the bot will fail.

6. Optional: From the **Assign PDF properties to a dictionary variable** list, select a dictionary variable to hold the file properties.
For more information, see [Using a dictionary variable for PDF properties](#) on page 2772.
7. Click **Save**.

Related tasks

[Using the Encrypt document action](#) on page 2764

Use the **Encrypt document** action to encrypt a PDF file.

Using the Get property action

Use the **Get property** action to obtain the properties of the PDF document.

1. In the **Actions** palette, double-click or drag the **Get property** action from the **PDF** package.
2. In the **PDF path**, select one of the following options to specify the location of the PDF:
 - **Control Room file**: Enables you to select a PDF file that is available in a folder in the Control Room.
 - **Desktop profile**: Enables you to select a PDF file that is available on your device.
 - **Variable**: Enables you to specify the file variable that contains the location of the PDF file.
3. From the **File is protected** field, select **Yes** if the file is encrypted and provide the **User password** or **Owner password**.
4. From the **Assign PDF properties to a dictionary variable** field, choose either a dictionary variable or multiple variables to hold the field values.
To assign the output to a dictionary variable, map the PDF properties such as **File**, **Author**, **Title**, and **Subject** to the corresponding dictionary keys.
5. Click **Save**.

Using the Merge documents action

Use the **Merge documents** action to merge multiple PDF files into a single PDF file.

1. In the **Actions** palette, double-click or drag the **Merge documents** action from the **PDF** package.
2. Click **Add PDF document** to provide details on the first PDF file.
The **Add PDF document** window appears.
3. In the **PDF path**, select one of the following options to specify the location of the PDF:
 - **Control Room file**: Enables you to select a PDF file that is available in a folder in the Control Room.
 - **Desktop profile**: Enables you to select a PDF file that is available on your device.
 - **Variable**: Enables you to specify the file variable that contains the location of the PDF file.
4. Optional: In the **User password** or **Owner password** field, enter a password to restrict access to the encrypted PDF file.
 - **User password**: Allow users to perform specific operations on the encrypted PDF file.
 - **Owner password**: Allow users to use a password to open the file.
5. In the **Page range** field, select one of the following options:
 - **All pages**: Selects all the pages in the PDF file.
 - **Pages**: Enter the page numbers of the pages that you want to merge.

Note: If you entered 1-3, 5-7, 8, 10 or 10, 8, 5-7, 1-3 in Enterprise 11, the output was pages 1,2,3,5,6,7,8,10. In Automation 360, if you enter the input as follows:

- In ascending order 1-3, 5-7, 8, 10, the output of the pages is 1,2,3,5,6,7,8,10
 - In descending order 10, 8, 5-7, 1-3, the output of pages is 10,8,5,6,7,1,2,3
-

6. Click **Yes, Add**.
7. Repeat Steps 2 through 6 to provide details on additional PDF files.
To modify the details of, or delete a PDF file, open the actions menu (the vertical ellipsis to the right of the file).
8. Place the files in the order that they should appear in the merged file.
To move a file, open the actions menu. Then use the **Move up** or **Move down** options.
9. In the **Output file path** field, specify a name and location for the merged file.
You must include the .pdf extension in the name of the decrypted file. For example, if the file name is `June_Quarter_report`, the .pdf extension is `June_Quarter_report.pdf`.
10. Select the **Overwrite files with the same name** check box to overwrite existing files with the same name.

Note: If this option is not selected and the bot encounters a file with the same name at the specified location, the bot will fail.

11. Click **Save**.

Using the Split document action

Use the **Split document** action to split a PDF file into multiple files.

To split a PDF file into multiple files, follow these steps:

1. In the **Actions** palette, double-click or drag the **Split document** action from the **PDF** package.
2. In the **PDF path**, select one of the following options to specify the location of the PDF:
 - **Control Room file**: Enables you to select a PDF file that is available in a folder in the Control Room.
 - **Desktop profile**: Enables you to select a PDF file that is available on your device.
 - **Variable**: Enables you to specify the file variable that contains the location of the PDF file.
3. Optional: In the **User password** or **Owner password** field, enter a password to restrict access to the encrypted PDF file.
 - **User password**: Allow users to perform specific operations on the encrypted PDF file.
 - **Owner password**: Allow users to use a password to open the file.
4. In the **Output file creation options**, select one of the following options to specify how to split the PDF file:
 - **Number of pages per extracted PDF**: Enables you to specify the number of pages each new file will contain. For example, you can enter 8 if you want each output file to contain only 8 pages.
 - **Single file with selected pages**: Enables you to create a single output file that contains the pages you have specified from the original file.
 - **Blank page as a separator**: Creates a new output file whenever a blank page is encountered in the original PDF file.

PDF split separates a blank page from pages with scanned images.
 - **Bookmark level per file**: Enables you to split the PDF file according to the bookmark level available in the file. For example, if a file contains three bookmark levels, you can split the PDF file based on these three levels.

If you selected this option, specify the bookmark level in the **Bookmark Level** field.
5. In the **Folder path** field, specify the location.
6. In the **File prefix** field, enter a value.

The image files are suffixed with index numbers. For example, if you have specified **Report** as the **File prefix**, the name of the image files will be **Report_1**, **Report_2**, and so on.
7. Select the **Overwrite files with the same name** check box to overwrite existing files with the same name.

Note: If this option is not selected and the bot encounters a file with the same name at the specified location, the bot will fail.

8. Optional: From the **Assign PDF properties to a dictionary variable** list, select a dictionary variable to hold the file properties.

For more information, see [Using a dictionary variable for PDF properties](#) on page 2772.
9. Click **Save**.

Using a dictionary variable for PDF properties

When you automate a PDF-related task, Automation Workspace retrieves various properties of the file and stores the values of these properties in a dictionary variable.

Automation Workspace retrieves the PDF file name and extension, title, subject, and author. The file properties are stored in a dictionary variable within the following keys:

- pdfTitle
- pdfFilename
- pdfSubject
- pdfAuthor

The system automatically associates the properties of a PDF with the appropriate dictionary keys.

For example, if you create a dictionary variable Test and want to log the file name and author, you must enter `Test {pdfFilename}` and `Test {pdfAuthor}` in the appropriate fields.

PGP package

Use the PGP (Pretty Good Privacy) package to automatically encrypt and decrypt files for security.

The PGP package supports two types of encryption, symmetric (single key) and asymmetric (pair of keys) :

- **PGP symmetric** : Requires a single key to encrypt and decrypt files.
- **PGP asymmetric**: Requires PGP public and private key to encrypt and decrypt files.

Note: The system outputs an error when the proper file extension is not present in the path.

- Public key: File name specified for Public Key is not valid.
 - Private key: File name specified for Private Key is not valid.
-

Actions in the PGP package

The PGP package includes the following actions:

Action	Description
Create keys	See Create keys action in PGP on page 2773.
Decrypt files	Decrypts encrypted files. See Using the Decrypt files action on page 2773
Encrypt files	Encrypts files to enable users to send them over the internet securely. See Using the Encrypt files action on page 2774

[PGP package updates](#) on page 882

Review the updates in released versions of the PGP package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Create keys action in PGP

Use the **Create keys** action in the PGP package to create a pair of public and private encryption keys.

Settings

- In the **Location to save public key file** field, specify the path to the text file where to save the public key.
- In the **Location to save private key file** field, specify the path to the text file where to save the private key.
- In the **Password to protect private key file** field, select a credential variable or enter a value.
- Select the **Overwrite files with the same file name** check box to replace files with the same name.

Using the Decrypt files action

Use the **Decrypt files** action to retrieve the contents of encrypted files and folders.

To decrypt a file or folder, do the following steps:

1. Double-click or drag the **Decrypt** action from the PGP package.
2. Select either the **Passphrase** or **Public key file** encryption type.
 - If you have selected **Passphrase**, enter the value or select a credential variable.
 - If you have selected **Private key file**, provide the private key file path.

Optional: In the **Password to protect private key file** field, select a credential variable or enter a value.
3. In the **Source folder/file(s)** field, specify the folders or files to decrypt.

This field supports wildcard characters in the file name and extension. Use an asterisk (*) to substitute for one or more unknown alphanumeric characters or symbols.
4. In the **Destination folder/file(s)** field, specify the location where to save the decrypted folders and files.

This field supports wildcard characters in the file name and extension. Use an asterisk (*) to substitute for one or more unknown alphanumeric characters or symbols.
5. Select the **Overwrite Files** option to replace files with the same name.
6. Select the **Remove file extension** option and specify the extension name.
7. Click **Save**.

Using the Encrypt files action

Use the **Encrypt files** action to prepare files and folders to be shared securely.

To encrypt the files or folder using a public key, create a public-private key pair using the **Create keys** action.

To encrypt a file or folder, do the following steps:

1. Double-click or drag the **Encrypt** action from the PGP package.
2. Select either the **Passphrase** or **Public key file** encryption type.
 - If you have selected **Passphrase**, enter the value or select a credential variable.
 - If you have selected **Public key file**, provide the public key file path.
3. Select the **Encryption algorithm**.
Choose from:
 - AES128
 - AES192
 - AES256
 - Blowfish
 - CAST5
 - Idea
 - TripleDES
 - TwoFish256
4. In the **Source folder/file(s)** field, specify the folders or files to encrypt.
This field supports wildcard characters in the file name and extension. Use an asterisk (*) to substitute for one or more unknown alphanumeric characters or symbols.
For example:
 - Enter `C:\PGP\encrypt*.csv` to select the .csv files that start with the word encrypt.
 - Enter `C:\PGP*encrypt*.*` to select files of any extension that contain the word encrypt.
5. In the **Destination folder/file(s)** field, specify the location where to save the encrypted folders and files.
This field supports wildcard characters in the file name and extension. Use an asterisk (*) to substitute for one or more unknown alphanumeric characters or symbols.
6. Enter a value to append to the extension of the destination file.
7. Select the **Overwrite Files** check box to replace files with the same name.
8. Select the **Compression type**.
Choose from:
 - None
 - zip
 - bzip2
 - zlib
9. Select the **Armor data (text output)** check box to enable ASCII Armor output.
10. Click **Save**.

Play Sound package

The Play Sound package contains actions that enable you to play a beep sound and media file before or after an action is executed in a bot.

The Play Sound package includes the following actions:

Action	Description
Play beep	See Play beep action on page 2775.
Play media file	See Play media file action on page 2775.

Related reference

[Play Sound package updates](#) on page 883

Review the updates in released versions of the Play Sound package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Play beep action

The **Play beep** action enables you to play a beep sound before or after an action is executed.

Play media file action

The **Play media file** action enables you to play an audio file before or after an action is executed.

Settings

From the **Select a file to play** field, select one of the following tabs to specify the location of the media file:

- **Control Room file:** Use a file that is available on the Control Room.
- **Desktop file:** Use a file that is available on a device.
- **Variable:** Use a variable to specify the file location.

Note: Only `.wav` and `.mp3` files are supported and do not require any media player installed on the device.

Printer package

Use the actions in the Printer package to automate retrieving and setting the default printer and removing a printer from the list of available printers.

Actions in the Printer package

The Printer package includes the following actions:

Action	Description
Get Default	See Get default action on page 2776.
Remove	See Remove action on page 2776.
Set Default	See Set default action on page 2776.

Related reference

[Printer package updates](#) on page 884

Review the updates in released versions of the Printer package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Get default action

The **Get default** action enables you to retrieve the default printer and assign a value to a string variable.

Settings

- Click the **Select the destination string variableChoose a variable** drop-down menu to select a variable.
- (Optional) Click **Create variable** icon if you do not have an existing variable.

Remove action

The **Remove** action enables you to delete or remove a printer.

Settings

- Click the **Enter the printer name** drop-down menu to view a list of available printers, and select a printer that you want to remove.
- (Optional) If the available printers are not listed, click the **Refresh options** icon.

Set default action

The **Set default** action enables you to set a default printer.

Settings

- Click the **Enter the printer name** drop-down menu to view a list of available printers, and select a printer that you want to set as the default one.
- (Optional) If the available printers are not listed, click the **Refresh options** icon.

Process Composer package

This package contains actions that enable you to configure bots to work on requests, tasks, and team members.

Note: The Process Composer package was previously known as AARI Web package.

Before you start

Ensure you have met one of the following conditions in order to run this package:

Condition 1

- Access to a process in an assigned team.
- Access to an AARI User license.
- A system-created **AAE_Robotic_Interface User** role for the AARI User.

Condition 2

- Access to a Bot Runner license (Attended or Unattended) or Bot Creator license.
- A user-created role with the **View My Bots** and **Run My Bots** permissions.

Actions in the Process Composer package

The Process Composer package includes the following actions:

Action	Description
Assign Human Task	See Assign Human Task action on page 2778.
Cancel Human Task	See Cancel Human Task action on page 2778.
Create a Request	See Create a Request action on page 2779.
Get Storage file	See Get Storage file action on page 2780.
Query Requests	See Query Requests action on page 2781.
Query Human Tasks	See Query Human Tasks action on page 2782.
Team Members	See Team Members action on page 2782.
Upload Storage file	See Upload Storage file action on page 2783.

Assign Human Task action

Assigns a specific task to a specified user.

Settings

- In the **Task ID to be assigned** field, select the variable of the Human Task. Find the Task ID as an output from the Query Task action.
- In the **User ID to assign to task** field, select the variable of the user. Find the User ID as an output from the Query Member action.

For the task and user ID, you can select a value from the **Variable** or **Global value** options.

- Optional: In the **Assign the result to variable** field, assign a variable to store as an output. The output is stored as a string value.

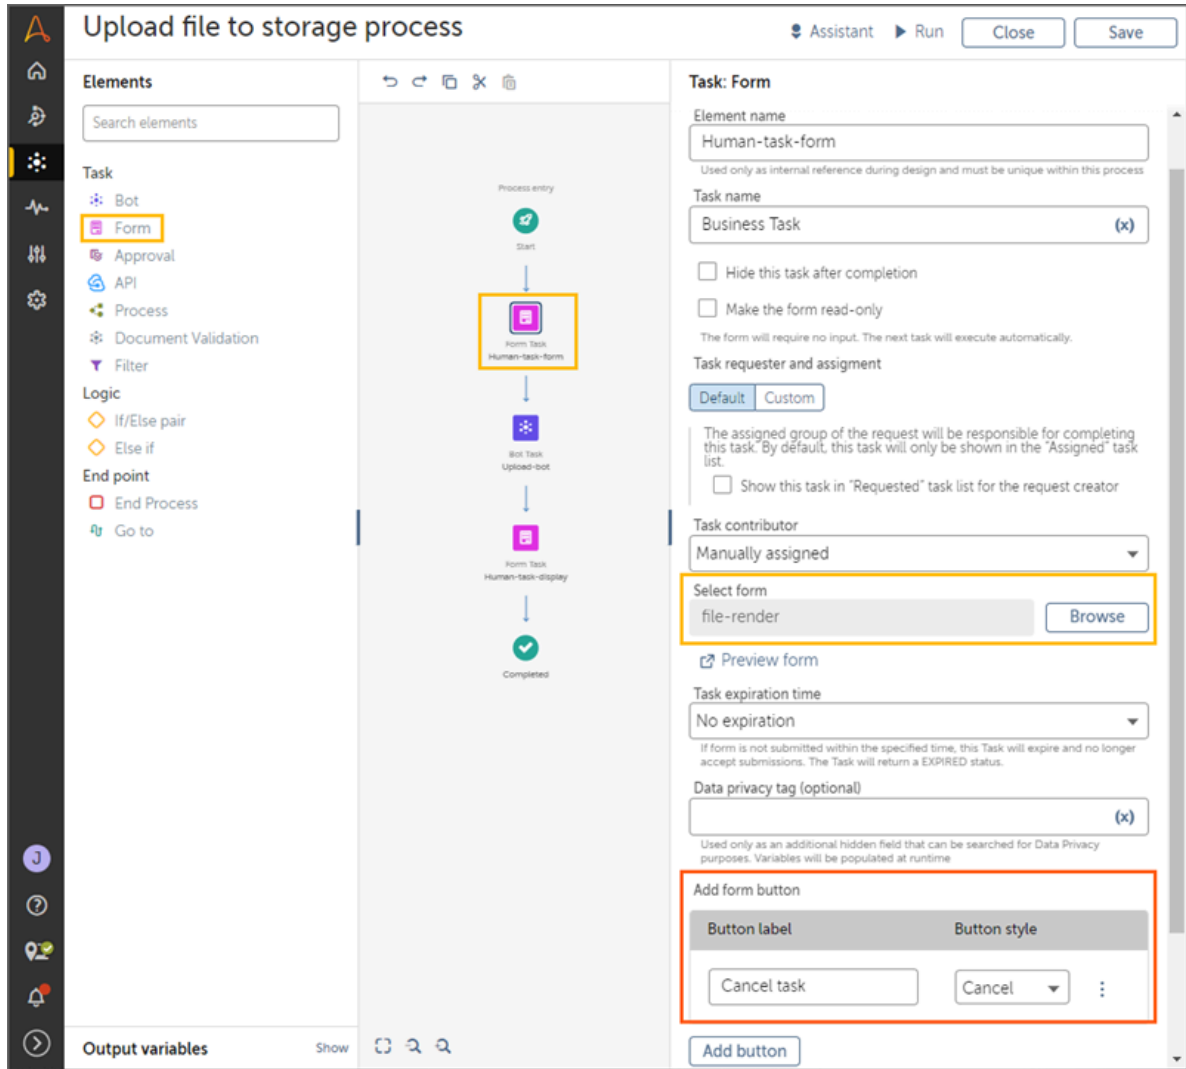

Cancel Human Task action

This action cancels a human task. Some configuration is required.

Settings

The cancel action is only valid when the form of the human task has a button of type **Cancel**. The user then has the control when running the task to cancel the form.

Note: Although the cancel button ends the form, to cancel the process you should use if/else logic to move the process to the end point when cancel is selected.

- In the **Task ID to cancel** field, specify a value.
For the task, you can select a value from the **Variable** or **Global value** options. The variable option enables you to add predefined variables.
- Optional: In the **Assign the result to variable** field, assign a variable to store as an output.
The output is stored as a string value.

Create a Request action

Creates a request with input values.

Settings

- In the **Actions** palette, double-click or drag the **Create a Request** action from the **Process Composer** package.

- In the **Public Process** field, browse and select the public process. The initial form fields from the process are displayed in the **Input values** field. These fields are from supported interactive form elements.
- In the **Input values** field, enter the values or variables to complete the required information to the initial form.

Note: For passing the values through variables, create a custom variable of any type: **String**, **Number**, **Datetime**, **Boolean**, **Dictionary**, **Table**, or **File**. Use the **Dictionary** variable for completing the check box information in the initial form. Enter the variable information in the **Type**, **Subtype**, **Key**, and **Value** fields. In the **Subtype** field, choose **Boolean**. Follow the format convention while creating **Dictionary** variables.

For example, consider the check box attributes as San Jose, Atlanta, and Sacramento, and we want to select the value Atlanta in the initial form field. Create a **Dictionary** variable of subtype **Boolean** in the format as follows:

Name: CheckBoxGroup0

Attributes	Key	Value
San Jose	CheckBoxGroup0_0	false
Atlanta	CheckBoxGroup0_1	true
Sacramento	CheckBoxGroup0_2	false

Note: When passing values of a table, the schema of the input table and schema of the initial form (in the process) needs to be the same for the bot to execute.

- Optional: In the **Assign the Request ID to** field, assign a variable to store as output. This returns the ID of the created request.
- Optional: In the **Assign the Request Reference to** field, assign a variable to store as output. This returns the ID of the request that was created.
- Click **Save**.

Get Storage file action

Downloads a storage file to a local device from a specified path.

Settings

Important: The Get Storage file action requires the matching of versions between the process version and the package version. Processes created before Automation 360 v.25 must be used with package versions from before Automation 360 v.25. Similarly, processes created after Automation 360 v.25 must be used with package versions after Automation 360 v.25.

- Specify the storage file URI in the **Variable** field.
Enter your file input variable.

Note: You must only use the **Variable** option and the variable must be a file input that is populated from the process (**Select File** in **Human Task**). Do not use the **Control Room file** and **Desktop file** options.

- In the **Full path of file in local device to be saved to**, specify the path to store your file.
You can select from **Variable** or **Global value** option. The variable option enables you to add a user-defined value, clipboard, string (enter, newline, separate, etc), system (task name, control room URL, etc), predefined variable package (date, minute, day, time, IP address, operating system, etc), or table analytic value.
- Optional In the **Result** field, choose a variable.
The output is stored as a variable.

Query Requests action

Create custom filters with sorting capabilities for requests.

Settings

- Select a filter.

Note: The filters for process and request titles, tags, IDs, team name, and PII tags have the same list of options.

- Specify the string value in the **List** or **Variable** field.
 - Specify your type in the **List** or **Variable** field.
 - **List:** Input your value information in the **Type** and **Value at 0** fields.
 - Optional: In the **Add** field, add more values.
 - **Variable:** Enter your custom variable.
- In the **Request Status** field, select a status.
You can choose **OPENED**, **SUCCESS**, **ERROR**, and **CANCELLED**
- In the **Page** field, specify a value.
 - In the **Table start at offset of data** field, enter a value.
 - In the **Number of rows per page** field, enter a value.
The default value is set **200** for number of rows.
- In the **Sort** field, specify the option.
 - In the **Direction** field, select **Descending** or **Ascending**.
The default value is set to **Descending** for the direction.
 - In the **Select sort column** field, select an option.
You can choose between process title or the request creation, ID, title, status, or PII tag.
 - Select the **Enable 2nd degree sort** and specify the **Direction** and **Select sort column** fields.
- In the **Assign the result to variable** field, assign a variable to store as an output.
The output is stored as a table value.

Query Human Tasks action

Create custom filters with sorting capabilities for tasks.

Settings

- Select a filter.

Note: The filter for process and request titles, tags, IDs, status, team name, and PII tags provide the same list of options.

- Specify the string value in the **List** or **Variable** field.
 - Specify your type in the **List** or **Variable** field.
 - **List:** Input the value information in the **Type** and **Value at 0** fields.
 - Optional: In the **Add** field, add more values.
 - **Variable:** Enter your custom variable.
- In the **Request Status** field, select a status.

You can choose **OPENED**, **SUCCESS**, **ERROR**, and **CANCELLED**
- In the **Task State** field, select a status.

You can choose **IN_PROGRESS** and **COMPLETED**.
- In the **Page** field, specify a value.
 - In the **Table start at offset of data** field, enter a value.
 - In the **Number of rows per page** field, update the value.

The default value is set to **200** for number of rows.
- In the **Sort** field, specify the following options.
 - In the **Direction** field, select **Descending** or **Ascending**.

The default is **Descending** for the direction.
 - In the **Select sort column** field, select an option.

You can choose from the request and tasks IDs, titles, creation, status, or PII tags.
You can choose from the request reference and task IDs, titles, creation, status, or PII tags.
 - Select the **Enable 2nd degree sort** and specify the **Direction** and **Select sort column** fields.
- In the **Assign the result to variable** field, assign a variable to store as an output.

The output is stored as a table value.

Team Members action

Retrieves a the list of members in a team.

Settings

- In the **Supply team ID to query it's members** field, specify a value.

For the supply team ID, you can select a value from the **Variable** or **Global value** options. The variable option enables you to add predefined variables ranging from time (minute, hour, day, month, year, etc) or system usages (CPU and RAM).

- In the **Supply team reference to query its members** field, specify a value.

For the supply team reference, you can select a value from the **Variable** or **Global value** options. With the variable option, you can add predefined variables ranging from time (minute, hour, day, month, year, and so on) or system usages (CPU and RAM).

- In the **Assign the result to variable** field, assign a variable to store as an output.

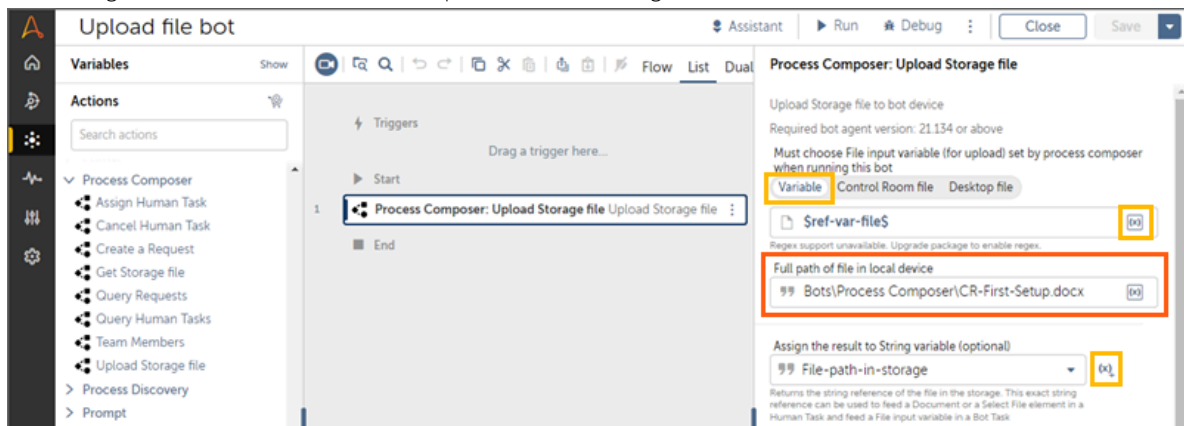

The output is stored as a table value.

Upload Storage file action

Maps a file to use in a process.

Settings

When using this action, the following best practices should be used. The image demonstrates these best practices in configurations.

- The file should first be saved as a variable using **File** type and marked as **input**. This variable is then selected as the **File input variable** for the action.

Note: Variable is the only valid option. The file is stored in the bot run device through this predefined variable.

- Enter the full path of the exact location of the file on the desktop or local device.
- Assign the result as a string variable that holds the storage path for the file after upload. This output variable must be string and should be used to feed a Select File element of a form or another File input variable of a bot.

See, [Example: Use Select File element to upload and download files](#) on page 3330.

Example of using Create a Request action

The **Create a Request** action from the Process Composer package enables you to create a new request in Automation Co-Pilot on the web through a bot. In this example, use the **Create a Request** action to pass data through bot variables to initial form of the process.

- You must have a Bot Creator license and be assigned a custom role with the following permissions:
 - Check-in and check-out permission
 - Create folder permission
- Create a process and check-in the process to the public workspace
- Assign at least one team to the process with the default team selected
- Select the **by bot** option in the **Request creation** field

In this example, we will create a process to register new employee details in the company database. The initial form contains basic information such as Name, ID, Date of Birth, Gender, and Location. We will pass the initial form data through bot variables.

1. Log in to the Control Room as a Bot Creator user.
2. Create the initial form.
 - [Create a form](#) on page 3214.
 - a) On the left plane, click **Automation**.
 - b) Click **Create new > Form**.
 - c) Enter the form name `employee_register_initial_form`.
 - d) Enter the folder location `Bots\Employee Registration`.
To change where your form is stored, click **Choose** and follow the prompts.
 - e) Click **Create & edit**.
 - f) Use the following **Elements** and **Element label** in the form.

Elements	Element label
TextBox	Full Name
Number	ID
Date	Date of Joining
Dropdown	Gender
Checkbox	Location
Select File	Resume

- For the **Dropdown** element, enter `Male, Female` in the **Enter list items separated by commas** field.
- For the **Checkbox** element, click the **plus** icon in **Checkbox content** field and add the locations `San Jose, Tokyo, India`.
- For the **Select File** element, you can limit the file type which can be uploaded by specifying it in the **Enter supported file format separated by commas** field. For example; `doc, gif, pdf, png, txt, xls`.

- g) Click **Save**.
- h) Click **Close**.
3. Create a new process.
- In the same folder location, click **Create new > Process**.
[Create a process automation in Process Composer](#) on page 3312.
 - Enter the process name `employee_register`.
 - Click **Create & edit**.
 - Click **Start** to add an initial form to the process.
 - In the **Select initial data form** field, browse and select the initial form, `employee_register_initial_form`.
 - Select AARI Storage in the **File upload storage** dropdown.
 - Provide **Request title** as `Employee Registration`.
 - Click **Save**.
 - Click **Close**.
 - Check in this process to the public workspace.
4. Create a new bot.
- In the same folder location, click **Create new > Bot**.
 - Enter the bot name `employee_register_request_bot`.
 - Click **Create & edit**.
5. Create the following variables:
- `emp_name`: String type; use as input.
 - `emp_id`: Number type; use as input.
 - `emp_date_of_joining`: Datetime type; use as input.
 - `emp_gender`: String type; use as input.
 - `emp_location`: Dictionary type, Boolean subtype; use as input. From the check box attributes given above, if you want to select the value San Jose for the location attribute in the initial form field, click the **plus** and create the dictionary variable in the format as given below:
- Name: `emp_location`
- | Attributes | Key | Value |
|------------|-------------------------------|-------|
| San Jose | <code>CheckBoxGroup0_0</code> | True |
| Tokyo | <code>CheckBoxGroup0_1</code> | False |
| India | <code>CheckBoxGroup0_2</code> | False |
- `emp_resume`: File type; use as input, select **Desktop folder or file** for the **Default value** and browse and select the file you want to upload.
 - `employee_registration_request_id`: Number type; use as output.
6. Use the **Create a Request** action from Automation Co-Pilot Web package.

- a) In the **Actions** palette, double-click or drag the **Create a Request** action from the **Process Composer** package.
- b) In the Public Process field, browse and select the public process `employee_register`. The initial form fields from the process are displayed in the **Input values** field. These fields are from supported interactive form elements.
- c) In the **Input values** field, enter the values or variables to complete the required information to the initial form as given below:
 - `emp_name: emp_name`
 - `emp_id: emp_id`
 - `emp_date_of_joining: $emp_date_of_joining$`
 - `emp_gender: $emp_genders$`
 - `emp_location: $emp_location$`. To select the location San Jose in the initial form field, add the key and value pair for the attributes as given below:

Attributes	Key	Value
San Jose	CheckBoxGroup0_0	True
Tokyo	CheckBoxGroup0_1	False
India	CheckBoxGroup0_2	False

- `emp_resume: emp_resume`
 - `employee_registration_request_id: $employee_registration_request_id$`
- d) Click **Save**.
 - e) Click **Close**.
7. Deploy the bot.
- a) Click **Run**.
 - b) In the **Set input variables** field, enter the values for the input variable.
 - c) Click **Confirm**.

The bot deploys successfully and a new request is created through the default team assigned to the process. The initial form fields are filled with the input provided through the bot. In the web interface, an Automation Co-Pilot admin can verify that a new request is created, and the data has been selected properly.

Process package

The **Process** package contains a request action that enables the Control Room user to use this action and configure their bots.

Before you start

Note: The **Process** package has been renamed to the AARI Web package in Enterprise A2019.18 with the **Create a Request** action and additional new actions. The AARI Web package is now

renamed to the `Process Composer` package with the same actions, in Enterprise A2019.28. See [Process Composer package](#) on page 2777.

Ensure you have met one of the following conditions in order to run this package:

Condition 1

- Access to a process in an assigned team.
- Access to Automation Co-Pilot User license.
- A system-created **AAE_Robotic_Interface User** role for the Automation Co-Pilot user.

Condition 2

- Access to a Bot Runner license (Attended or Unattended) or Bot Creator license.
- A user-created role with the **View My Bots** and **Run My Bots** permissions.

Actions in the Process package

The **Process** package includes the following action:

Action	Description
Create a Request	<p>Creates a request.</p> <ul style="list-style-type: none"> • In the Select Process field, select or upload your process. • Specify your variable in the Dictionary or Variable field. <ul style="list-style-type: none"> • Dictionary: Input your variable information in the Type, Key, and Value fields. <p>In the Type field, you can choose between Any, String, Number, Datetime, or Boolean.</p> • Optional: In the Add field, add more dictionary variables. • Variable: Enter your custom variable. • Optional: In the Assign the Request ID to field, assign a variable to store as an output. <p>The output is stored as an ID value.</p>

Prompt package

Use the `Prompt` package to accept an input value, a yes/no response, or to open a file or folder.

Actions in the Prompt package

The `Prompt` package includes the following actions:

Action	Description
For file	See For file action in Prompt on page 2788.
For folder	See For folder action in Prompt on page 2788.
For value	See For value action in Prompt on page 2789.
For yes/no	See For yes/no action in Prompt on page 2789.

Related reference

[Message box package](#) on page 2691

Use the **Message box** action from the **Message box** package to insert a message box that shows a message when the task runs. For example, you can insert a **Message Box** action to follow a web form so that the action displays the message: Web Form Filled and Complete.

[Prompt package updates](#) on page 886

Review the updates in released versions of the Prompt package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

For file action in Prompt

The **For file** action in the **Prompt** package prompts you to select a single or multiple files on bot execution.

Settings

- In the **Prompt window caption** field, enter a window caption.
- In the **Prompt message** field, enter a message.
- In the **Assign the value to a variable** field, specify a list variable.

For folder action in Prompt

The **For folder** action in the **Prompt** package prompts you to choose a folder.

Settings

- In the **Prompt window caption** field, enter a window caption.
- In the **Prompt message** field, enter a message.
- In the **Assign the value to a variable** field, specify a variable.

For value action in Prompt

The **For value** action in the **Prompt** package prompts you to enter a value.

Settings

- In the **Prompt window caption** field, enter a window caption.
- In the **Prompt message** field, enter a message.
- In the **Assign the value to a variable** field, specify a variable.

For yes/no action in Prompt

The **For yes/no** action in the **Prompt** package prompts you to choose a Yes/No response.

Settings

- In the **Prompt window caption** field, enter a window caption.
- In the **Prompt message** field, enter a message.
- In the **Assign the value to a variable** field, specify a variable.

Python Script package

The Python Script package contains actions that enable Python Script functions in a task.

Before you start

Ensure the following requirements are met before using the Python Script package:

- The appropriate version of Python is installed on the device on which you want to execute the script.

Note: Python versions 2.x and 3.x are supported.

- The "PATH" environment variable is updated to the path of the Python folder.

To verify if the Python environment variable is set correctly, enter `Python` in the command prompt. If it returns the Python version that is installed, the path environment is set up correctly.

Perform the following actions within the Python Script package as part of using the set of available actions:

1. Open a Python Script file, or manually enter the script you want to run using the **Open** action. You must associate the details of the file or script you want to run with a session name.
2. Run the script using the **Execute function** or the **Execute script** action. You must use the same Python Script session name established in the **Open** action.

3. Close the Python Script session after running the script.

Note: When you run a bot that contains Python Script actions, the script runs in the background.

To review the bot launcher logs, navigate to `C:\ProgramData\AutomationAnywhere\BotRunner\Logs\<current month>\Bot_Launcher-<today's date>.log.zip`. Each zipped folder contains a file with data on the code execution, which is useful for debugging.

Actions in the Python Script package

The Python Script package includes the following actions:

Note: The **Open** action must be the first action to use the Python Script in a task. These actions can run a Python Script on Windows, Linux, and UNIX-based devices.

Action	Description
Close	See Close action on page 2791.
Execute function	See Execute function action on page 2791. For an example, see Example of using Python script to join a list on page 3079.
Execute script	See Execute script action on page 2791. For an example, see Create a PDF using Python script on page 2793.
Open	See Open action on page 2792.

[Python Script package updates](#) on page 887

Review the updates in released versions of the Python Script package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Close action

The Close action in the Python Script package closes the session.

Settings

Specify the same session name from the **Open** action.

Important: It is mandatory to close the session after the script is executed.

Execute function action

The Execute function action in the Python Script package enables you to execute a function within the Python Script package.

Settings

- In the Python **session** field, specify a session name. Use the same session name from the **Open** action.
- Specify the function name to run the function.
- Optional: Provide the arguments required for the function while storing the returned values in a variable.

This field supports Boolean, dictionary, list, number, or string variables.

Note: The interface allows you to select only one argument. Use a list variable to concatenate multiple arguments into one variable.

- Optional: In the **Assign the output to variable** field, specify the string variable.

Execute script action

The Execute script action in the Python Script package enables you to execute a script within the Python Script package.

Settings

- In the Python **session** field, specify a session name. Use the same session name from the **Open** action.
- Optional: In the **Assign the output to variable** field, specify the string variable.

If the bot executes the script successfully, this action returns the string `True`. Otherwise an error message appears.

The following example shows the difference between the **Execute Script** and **Execute function** actions.

When you open a new Python session, you provide a Python script or file. The script might contain a few lines of code to be executed or might contain a file of functions used to perform certain operations, such as:

```
#executable code flow
file = open("abc.txt", "w")
file.write("Some text")
file.close()

#functions, not in executable flow
def function1():
    return 9+10

def function2():
    return "Some Text"

def add(a,b):
    return a+b
```

- When you use the **Execute script** action, it will only execute the lines of code in the executable flow of the script. Any functions that are defined but not called will not be executed.
- When you use the **Execute function** action, the session can call any function in the script or file, and provide the arguments required for the function while storing the returned values in a variable.

Open action

The Open action in the Python Script package opens the session.

Settings

- In the Python **session** field, specify a session name. Use this same session name for other Python Script actions.
- In the Python field, choose one of the following options:
 - In the **Import existing file** option, select an existing Python Script file.

Note: If you are uploading a script from a file on your desktop, the file and any dependencies must be in a standalone folder. When you select a file for upload, all files and folders at the same folder level are uploaded.

- In the **Manual input** option, enter the Python Script.
- In the **Python runtime version** field, select **2** or **3** to specify the runtime version.

Note: Select the runtime version based on the version of Python installed on the device.

Create a PDF using Python script

Build a bot that runs Python script from a file and generates a PDF.

- To run Python script from Automation 360, you must already have the latest version of Python 3.x installed on your device.
- This example uses the FPDF library to generate the PDF. Therefore, install it before you start building this bot by copying and pasting the following line in the Windows command prompt:

```
pip install fpdf
```

See [FPDF project page](#).

1. Create a file in a standalone folder to hold the following Python script:
Insert your device username in the angle brackets.

```
from fpdf import FPDF
pdf = FPDF()
pdf.add_page()
pdf.set_font("Arial", size=12)
pdf.cell(200, 10, txt="Go Be Great!", ln=1, align="C")
pdf.output("C:/Users/<yourusername>/Desktop/sample_demo.pdf")
```

Note: If you are uploading a script from a file on your desktop, the file and any dependencies must be in a standalone folder. When you select a file for upload, all files and folders at the same folder level are uploaded.

2. Create a new bot:
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Bot**.
 - c) In the **Create Task Bot** window, enter the bot name.
 - d) Accept the default folder location: `\Bots\`
To change the default bot storage location, click **Choose** and follow the prompts.
 - e) Click **Create and edit**.
3. Provide the script with a **Python Script > Open** action:
 - a) Double-click or drag the **Python Script > Open**.
 - b) Select the **Import existing file** option.
 - c) Click **Browse** to select the .py file you created in Step 1.
4. Use a **Python Script > Execute script** action to tell the bot to run the script:
 - a) Double-click or drag **Python Script > Execute script**.
5. Close the script execution session with a **Python Script > Close** action:
 - a) Double-click or drag **Python Script > Close**.
 - b) Click **Save**.
6. Click the **Run** icon.

The bot creates a PDF on the desktop with the text Go Be Great!.

To review the bot launcher logs, navigate to `C:\ProgramData\AutomationAnywhere\BotRunner\Logs\<current month>\Bot_Launcher-<today's date>.log.zip`. Each zipped folder contains a file with data on the code execution, which is useful for debugging.

If the bot does not create a file, change the last line in the Python script:

```
pdf.output(r"C:/Users/<yourusername>/Desktop/sample_demo.pdf")
```

Record package

The **Record** package enables you to perform various operations on record-type variables. A record-type variable holds a row of data extracted from a database, spreadsheet, or table in name-field pairs. The fields can store values of Boolean, datetime, number, or string data type.

Actions in the Record package

The **Record** package includes the following actions:

Add column	See Add column action in the Record package on page 2794.
Assign	See Assign action in the Record package on page 2796.
Delete column	See Delete column action in the Record package on page 2796.
Update column	See Update column action in the Record package on page 2797.

Related reference

[Record package updates](#) on page 888

Review the updates in released versions of packages such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Add column action in the Record package

Use the **Add column** action to add a new column to an existing record variable at a specific index position, and store the output within a destination record variable. You can then insert this destination record variable into a Data table or Dictionary object.

Settings

- In the Actions palette, double-click or drag the **Add column** action from the **Record** package.
- Click the **Source record variable** drop-down and select an existing source record variable.
 - If there are no existing record variables, create one.
- (Optional) Enter a name for the column you want to add in the **Column name** field.

Note: The column name is case sensitive. An error message is displayed if you try to add an existing column name. However, you can add a duplicate entry of an empty column name.

- Click the **Column type** drop-down and select one of the following options as the type for the column that you are adding:

Option	Description
String	Enter a string value that you want to set to the new column. To insert a variable into the Value field, click the Insert a value icon and select a variable.
Number	Enter a numeric value that you want to set to the new column in the Value field.
Boolean	Click True or False tab to select a Boolean value, or click the Variable tab to insert an existing Boolean variable.
Datetime	<p>Use the Datetime tab to select the following:</p> <ul style="list-style-type: none"> Select a date from the calendar. Select the time. Use the drop-down to select a time zone. <p>The Datetime is empty by default. If you run the bot without changing the default value, the action will use the current date, time and time zone of the system.</p>

- Use the **Insert column at** field to select one of the following options to specify the index:
 - first index:** to insert the column at the first position (0 index) in a record variable.
 - last index:** to insert the column at the last position of the record variable.
 - specific index:** to insert a column at a specific position in the record variable.

For example, to insert a column at index position 1, enter 0. The index number starts from 0. The first item in the record variable is at position 0, the second item at 1, and so on.

- Click the **Destination record variable** drop-down to select an existing destination record variable.

(Optional) Click the **Create variable** icon to create a record variable. For more information, see [Record variable](#) on page 2250.

Assign action in the Record package

Use the **Assign** action to assign the value of source record variable to the destination record variable.

Settings

- In the Actions palette, double-click or drag the **Assign** action from the **Record** package.
- Click the **Select the source record variable** drop-down and select an existing source record variable.

If there are no existing record variables, create one.

- Use the **Select the destination record variable** field to select one of the following tabs for the destination record variable:
 - Multiple variables:** To store the output in multiple variables by providing the key and the variable to which the key is mapped. This variable can be of any type, such as **String**, **Number**, **Datetime**, **Boolean** and so on. For example, if your source record variable contains two entries; name and contact number, you can store the output as given below:

Key	Map to variable
Name	StrName
Contact number	MobileNo

The variables StrName and MobileNo are **String** and **Number** type variables respectively.

- Record:** To store the output in a record-type variable.

Click the **Choose a variable** drop-down to select an existing variable or create one.

Delete column action in the Record package

Use the **Delete column** action to delete a column from an existing record variable based on the column name or index.

Settings

- In the Actions palette, double-click or drag the **Delete column** action from the **Record** package.
- Click the **Source record variable** drop-down and select an existing source record variable.

If there are no existing record variables, create one.

- Use the **Delete column by** field to select one of the following options to delete a column :
 - Column index:** to specify a column position in the record variable.
Indexing starts at 0. For example, enter 5 to indicate the sixth column from the left.
 - Column name:** to specify the name of an existing column.

Note: The column name is case sensitive. Ensure that you provide the correct column name. If there are duplicate column names, then the first matching column from the left will be deleted.

- Click the **Destination record variable** drop-down to select an existing destination record variable.

(Optional) Click the **Create variable** icon to create a record variable. For more information, see [Record variable](#) on page 2250.

Update column action in the Record package

Use the **Update column** action to update the value of a column within an existing record variable at the specified index or name, and store the output in the destination record variable.

Settings

- In the Actions palette, double-click or drag the **Update column** action from the **Record** package.
- Click the **Source record variable** drop-down and select an existing source record variable. If there are no existing record variables, create one.
- Use the **Update column by** field to select one of the following options to update a column:

- Column index:** to specify the column number.
Indexing starts from 0. Enter 5 to indicate the sixth column from the left.
- Column name:** to specify the name of a column.

Note: The column name is case sensitive. Ensure that you provide the correct column name. If there are duplicate column names, then the first matching column from the left will be updated.

- Click the **Column type** drop-down and select one of the following options as the data type for the column that you are updating:

Option	Description
String	Enter a string value that you want to set to the new column. To insert a variable into the Value field, click the Insert a value icon and select a variable.
Number	Enter a numeric value that you want to set to the new column in the Value field.
Boolean	Click True or False tab to select a Boolean value, or click the Variable tab to insert an existing Boolean variable.

Option	Description
Datetime	<p>Use the Datetime tab to select the following:</p> <ul style="list-style-type: none"> • Select a date from the calendar. • Select the time. • Use the drop-down to select a time zone. <p>The Datetime is empty by default. If you run the bot without changing the default value, the action will use the current date, time and time zone of the system.</p>

- Click the **Destination record variable** drop-down to select an existing destination record variable.

(Optional) Click the **Create variable** icon to create a record variable. For more information, see [Record variable](#) on page 2250.

Recorder package

Recorder package captures a series of tasks in a process and then automates them. You can automate your business applications (for example, desktop, Web, SAP, and Java applications) using the Recorder to capture actions performed on application objects such as a text box, button, table, radio button, combo box, and list view.

Automation 360 extension setting

If the bot execution takes longer when you use the Recorder to automate a static page running on the Google Chrome or Microsoft Edge browser, then follow these steps to enable the setting in the Automation 360 extension:

- Click the extensions icon at the top right corner of the browser window.
- Click the vertical ellipses next to the Automation 360 plugin and select **Manage extension**.
- Enable the **Allow access to file URLs** option.
- Restart the browser and run the bot.

Benefits of using Recorder package instead of SAP package

We recommend that you use the Recorder to automate SAP applications. When you use the Recorder to automate SAP applications, you have the following benefits:

- You can automate objects without creating a session. When you use the SAP package you must create a session.
- You can automate the object directly without generating the field paths or having any prior knowledge of the field paths. When you use the SAP package, the package will execute actions directly on control field paths when properties in the search criteria match the object that the bot searches during execution.

- If the Recorder runtime window overlaps the object that you want to automate, then the Recorder hides the runtime window before you automate the object.
- Recorder supports actions in the If, Loop, and Wait packages that enables you to check if an object exists in the specific browser or window.

Note: When compared to the Recorder package, the SAP package enables you to automate an application without activating the application window.

Capture using Recorder

Use the **Capture** action to capture an interaction with a user interface (UI) object. This action enables you to add a single interaction when you are building a bot.

Note:

- The Capture action replaces the Object Cloning command from Version 11.3.
- If you open a window in any of the supported browsers with a user account that is different from the one used to log in to the computer, the Recorder might not capture and play the control actions accurately.

[Using the Capture action](#) on page 2818

When you are automating web pages running on Google Chrome and Microsoft Edge browsers, the **Recorder > Capture** action no longer scrolls down the web page if the target object is visible on the screen. This improves the user experience and the reliability of automation when there is a fixed top pane on the web page and if some physical actions such as mouse clicks do not work as expected.

Use the **Recorder > Capture** action to automate objects successfully when your device credentials are entered in the UPN format.

Supported applications

You can automate the following applications running on Microsoft Edge Chromium with IE mode:

- Java web applications
- Applications that are accessed through the Citrix Workspace app.
- Citrix Virtual Apps

Note:

- To accurately capture or automate objects on SAP applications, we recommend that you enable scripting. If scripting is not enabled, the following prompt message is displayed below the bot runtime window:

`SAP scripting disabled: Enable scripting for more reliable captures`

If you do not enable scripting, instead of using SAP technology, the Recorder uses MSAA technology for capturing objects.

- When automating an Electron application, the Recorder captures specific controls on the application using the Microsoft UI Automation (COM) technology by default. This enables you

to automate Electron applications seamlessly without having to recapture the object with a specific technology.

Supported control types

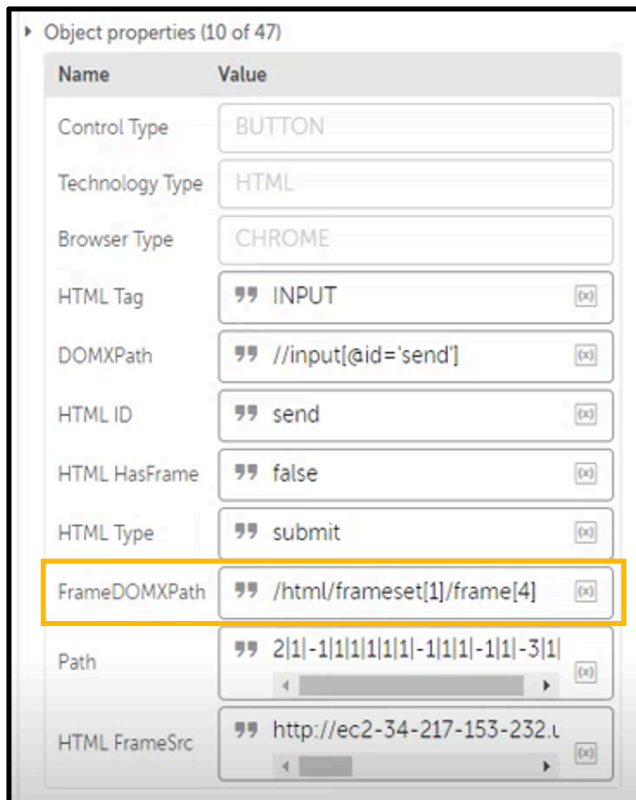

You can automate the following control types when you are automating a web page on a Google Chrome, Microsoft Edge Chromium, or Mozilla Firefox browser:

- Pop-up windows
- Alert dialog boxes
- Confirmation dialog boxes
- Prompt dialog boxes

Note: When you want to automate an alert dialog box on a web page, we recommend that you add a delay before the **Recorder > Capture** action because sometimes, the alert dialog box appears after a delay on the application window.

Cross-domain support

You can capture and automate objects inside a cross-domain IFrame that has multiple IFrames with same frame source and IFrames that are loaded dynamically during runtime in Google Chrome and Microsoft Edge Chromium browsers. After you have captured an object inside a cross-domain IFrame, the frame path is stored in the **FrameDOMXPath** property, by default.

The new **FrameDOMXPath** property identifies the frame in which the object is located. You must select this property to run the bot successfully to automate objects on a cross-domain IFrame.

Note:

- When you select the **FrameDOMXPath** property from the search criteria, do not change the value of this property.
- If you clear the **FrameDOMXPath** property from the search criteria, the Recorder fails to identify the frame.

Important: In the Google Chrome browser, you can capture and automate objects inside a cross-domain and use multiple frames with the same frame source.

Automate applications running as an admin user

You can capture objects on applications that are running as an administrator by selecting the **Capture and run with admin privileges** option from the Bot editor.

Before you automate applications running as an admin user, ensure the following:

- Bot Agent is installed in system profile.
- Bot Creators and Bot Runners have admin rights on the device to automate the applications.

When you select the **Start recording** option in the Bot editor to record multiple applications, and switch applications running in elevated and non-elevated mode, the bot might not be able to identify the change between modes. In such cases, for all captures on applications in elevated mode, select the **Capture and run with admin privileges** option and then re-capture the object.

Note: Elevated mode gives you permission to run applications as an administrator.

Important: When you try to automate any Java or SAP application that is non-elevated by using the Recorder in elevated mode, the bot encounters an error.

To avoid this error, de-select the **Capture and run with admin privileges** option from the Bot editor and run the Recorder in non-elevated mode to capture Java or SAP applications.

Object properties

When you select an object to capture, the Universal Recorder collects data on the object's properties in order to identify the object during run time. You can do the following with the object properties:

- Verify that the captured object properties match your intended object.

For example, when capturing a table from a website, ensure the **Control Type** and **HTML Tag** values are **TABLE**.

> Object properties (7 of 47)

Name	Value
Browser type	Google Chrome
Technology type	HTML
Control type	Table
HTML Tag	TABLE
DOMXPath	//div[@id='mw-content-tex
HTML HasFrame	false
Path	3 -1 -2 1 23
HTML FrameSrc	https://en.wikipedia.org/wik

- Retrieve a property value. Use the **Get property** action and enter the name of the property in the **Property name** field or select an object property from the list of available properties. The list includes suggested property values from the search criteria in the **Object Properties** table. To select an object property from the list of properties, move the mouse pointer to the right of the **Property name** field and click the arrow.

For example, to retrieve the text of a link, use the **Get property** action and enter `HTML InnerText` in the **Property name** field or select `HTML InnerText` from the list of properties.

- You can select a combination of properties for the bot to search the object in your business application window uniquely.

The search algorithm for the Recorder package ensures that when you run a bot an object is captured only if its properties match the exact search criterion that you selected in the **Object properties** table. If the properties of the object do not match the search criterion exactly, then the bot fails with an error message. However, if the search criterion includes a wildcard character, then the bot captures the first object that matches the criterion.

For example, to capture a text box from an application that has three text boxes named **firstname1**, **firstname2**, and **firstname3**, if you select **HTML name** as the search criterion, enter the value `firstname` in the HTML name field, and run the bot, then the bot fails with an error message because a text box with the HTML name `firstname` does not exist. However, in the **HTML name** field, if you enter `firstname*`, and run the bot, then the bot captures the first text box that matches the criterion.

Note: This functionality is available for the bots you create using the 2.4.0-20211016-070100 version of the Recorder package starting from Automation 360 v.23. If you have created bots using a previous version of the Recorder package, you must recapture the objects to use this functionality.

Actions performed on captured objects

After capturing the object, specify the action for the bot to perform on the object at run time. For example, when you capture a hyperlink, you can select to click the link or to retrieve the link text.

To see table of all objects and possible actions, see [Actions performed on objects captured with Universal Recorder](#) on page 2804.

Note: If you encounter an error when running a bot that captures an object from Internet Explorer and the error message is about Google Chrome, see [Your Chrome Plug-in is either not installed or disabled \(A-People login required\)](#).

Background processing

Background processing enables an automation that involves interacting with an application in the foreground (such as mouse clicks) to run in the background. We recommend that you use the option to run in background to increase the visibility of the target object and improve bot accuracy. The following actions support background processing:

- Click
- Set Text
- Get Text

Secure recording

When secure recording mode is enabled, bots do not display the target object images after capture. This ensures that sensitive data is not shown.

Note: Although the bots do not display the target images after capture, the images are still stored in the Control Room because they are required to run the bots.

When you record a task in secure recording mode, the **Preview** window temporarily shows an image of the captured area. This image is hidden after you navigate away from the Bot editor window or refresh it.

A user with admin privileges must enable this setting. See [Settings](#) on page 1728.

Proxy support

If your device is configured with a proxy, all outbound requests from this package are routed through the proxy server. See [Connect Bot Agent to a device with a proxy](#) on page 1293.

Use cases on how to use recorder

Use these example tasks to become familiar with the use of the recorder in building bots.

- [Example of entering data into a web form from a spreadsheet](#) on page 3074
- [Example of extracting data from a web table](#) on page 3071

Review the updates in released versions of the Recorder package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Actions performed on objects captured with Universal Recorder

After capturing the object, specify the action for the bot to do to the object at runtime. For example, if you capture a hyperlink, you can select an action to click the link or to retrieve the link text. Refer to the table below for the objects and their possible actions.

Note:

- After you have captured an object and open the **Action** drop-down list, the list might offer actions for an object that are not supported. Only use the actions for an object that are listed in the table below.
- You can capture any control type which is not yet supported by Microsoft UI Automation (COM) technology as **Client** control. You can perform all actions that are available in **Client** control type but only those actions that are supported for that specific control. For example, if you are capturing a slider control which is not yet supported by Microsoft UI Automation (COM) technology, it is captured as a **Client** control. You can perform only those actions that are supported by the slider control. For example, you can perform the **Click**, **Left click**, **Right click**, and **Double click** actions but you cannot perform the **Set text** action.

Object	Actions
Tree (Control is displayed as a ListView)	<ul style="list-style-type: none"> <li data-bbox="610 254 1412 348">• Get property: retrieves the value of the specified object property (such as the link text) and optionally saves it to a variable. For more information, see the Object properties section. <hr/> <p data-bbox="646 380 1412 506">Note: When you use the Microsoft UI Automation (COM) technology to capture the control, the Get property action does not retrieve the property of the item element and returns a blank value.</p> <hr/> <ul style="list-style-type: none"> <li data-bbox="610 527 1333 558">• Get total items: retrieves the number of items in the tree. <li data-bbox="610 562 1373 594">• Get selected index: retrieves the item's position in the menu. <hr/> <p data-bbox="646 625 1057 657">Note: Item index counts start at 1.</p> <hr/> <p data-bbox="646 709 1412 835">Note: When you use the Microsoft UI Automation (COM) technology to capture the control, the Get selected text action returns a list of items instead of a single item in a string similar to other technologies.</p> <hr/> <ul style="list-style-type: none"> <li data-bbox="610 856 1360 888">• Get selected text: retrieves the data from the selected item. <hr/> <p data-bbox="646 919 1412 1045">Note: When you use the Microsoft UI Automation (COM) technology to capture the control, the Get selected text action returns a list of items instead of a single item in a string similar to other technologies.</p> <hr/> <ul style="list-style-type: none"> <li data-bbox="610 1066 1349 1129">• Select item by index: selects the item that is located at the specified index. <hr/> <p data-bbox="646 1161 1057 1192">Note: Item index counts start at 1.</p> <hr/> <ul style="list-style-type: none"> <li data-bbox="610 1213 1393 1276">• Select item by text selects the item that matches the specified text. <hr/> <p data-bbox="646 1308 1195 1339">Note: The Assign value field is case-sensitive.</p> <hr/> <ul style="list-style-type: none"> <li data-bbox="610 1360 1406 1392">• Left click: use this action if the Click action fails during runtime. <li data-bbox="610 1396 781 1428">• Right click <li data-bbox="610 1432 805 1463">• Double click <hr/> <p data-bbox="610 1518 1406 1644">Note: When you capture a Tree control using Microsoft UI Automation (COM) technology and perform Left click, Right click, or Double click actions on the control, the actions will click on the point of capture.</p>

Using the Capture action

Use the **Capture** action to capture a single interaction (click, keystroke, or mouse movement) with an object control including a text box, button, table, menu, radio button, combo box, check box, list view, link, tree, or page tab.

- To use the Recorder, you must already have done the following:

- [Install Bot Agent and register device](#) on page 1288
- [Set user device credentials](#) on page 1295

- Configure device display and font scale to 100%.

If you are using Recorder package version 2.0.6-20200626-193519 or later, you can record tasks in Google Chrome, Internet Explorer, Java, Microsoft Active Accessibility, and Microsoft UI automation applications on a computer that has display scale configured to 100%, 125%, or 150%.

- If you are automating a task using a browser, configure the zoom level to 100%.

If you are using Recorder package version 2.0.6-20200626-193519 or later, you can record tasks in a Google Chrome browser that does not have a zoom level setting of 100%.

- If you are automating a task using a Google Chrome browser, ensure that the Automation Anywhere plug-in that corresponds with the Automation 360 build version is enabled.

[Browser requirements for Automation Workspace](#) on page 1154

- To automate web applications running on Microsoft Edge Chromium browser in Internet Explorer mode using the Universal Recorder, ensure that the Internet Explorer compatibility mode is enabled. The objects on the web applications are captured using HTML technology. To enable this mode, perform the following steps:

1. On the Microsoft Edge Chromium browser page, click **Settings**.
2. On the left panel, click **Default browser**.
3. Navigate to the **Allow sites to be reloaded in Internet Explorer mode** option and select **Allow**.
4. Click **Add** to add the URL of the page that you want to load in Internet Explorer mode.

Note: The pages that you add open in Internet Explorer mode for 30 days from the date when you add the page.

Considerations when recording a task:

- Use clicks when possible rather than shortcut keys.

When you click an object using the Recorder, it retrieves the object's properties that enable the bot to identify the object at runtime. Keyboard shortcuts are less reliable, so use them when it is not possible to automate the task by a clicking an object.

- If you are automating a task using a browser, do not use autofill to enter values into fields.
- Record the task at low speed.
- Avoid dragging windows during the recording process.
- Avoid clicking on applications that are not part of the process you are recording and automating.

- When Internet Explorer is used, the action waits until the browser is completely rendered and is in a ready state before executing the action.

To record a single interaction with an object control, follow these steps:

- Double-click or drag **Recorder > Capture**.
- Specify the window in which to capture an object.

Choose from the **Application**, **Browser**, or **Variable** tab.

Option	Description
Application	Select from a list of currently active windows. This option shows a list of all the application and browser windows that are open on the Bot Creator device.
Browser	Select from a list of supported browser tabs. Note: This option supports , Chromium-based , and browsers. For all other browsers, use the Application option.
Variable	Select an existing window variable to specify the title of the application window title.

- Optional: Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value.

For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*) -Notepad` for all window title names starting with `((\w*) -Notepad`, or use **Pattern** value as `((\w) \s) *document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.

- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

Note: During runtime, verify that the Task Bot identifies the correct window. If it does not, do the following:

- a) Open the application or browser window.
- b) Drag a **Window > Get active window title** action above the **Recorder > Capture** action.
- c) Insert a string variable into the **Assign the window title to variable** field.
- d) Drag a **Window > Set title** action below the **Window > Get active window title** action.
- e) In the **Window** field, insert the window variable generated by the **Recorder > Capture** action.
- f) In the **New window title** field, insert the string variable from the **Get active window title** action.
- g) Click **Save**.

-
4. Optional: Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.

- If the window is maximized when you record the task, this option is not selected.
- If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

-
5. Click **Capture object**.

The selected window appears.

6. Move the mouse over the object you want to automate, for example, a button, form field, or a table.

A red rectangular box appears around the object.

Note: If the box does not appear and you are capturing in either the Google Chrome, Microsoft Edge, or Mozilla Firefox browsers, verify that you have enabled the Automation Anywhere extensions for these browsers. See [Google Chrome browser extension requirements](#) on page 2174 for Google Chrome browser.

-
7. Click the object.

8. Review the **Object properties** table.

Following are the list of object properties that are selected by default based on the technology type:

Important: The following list does not include all the properties and is restricted to the most commonly used and important properties based on the technology type

Technology type	Object properties	Description
HTML Technology	Control type	This is a read-only property that shows the type of object captured, for example, text box or button.
	DOMXPath	<p>It is the path that is used to locate the control or object that is captured.</p> <p>DOMXPath can be of two types: Relative XPath and Absolute XPath.</p> <ul style="list-style-type: none"> • Absolute Xpath: It contains the complete path from the root element to the desired element. For example, an absolute Xpath for this topic would be <code>/html/body/div/div[1]/main/div[2]/div/div/div[2]/div/div/div[1]/div/article/main/article/div/p[1]</code> • Relative Xpath: This is a shorter path that refers to an element you want to identify. A relative path starts with a <code>//</code> symbol. For example, the relative XPath for this topic would be <code>//*[@id="cloud-using-recorder-action"]/div/p[1]</code> <p>For example, if you want to find the DOMXPath of a particular element on Google Chrome browser, perform these steps:</p> <ol style="list-style-type: none"> Select the element for which you want to extract the XPath. Right-click the element and select Inspect. Right-click the highlighted element in the Element tab. Go to Copy > Copy XPath to copy the relative path and select Copy > Copy full XPath to copy the absolute path.
	Path	It is a numeric representation of the position of a particular control in an application. For web applications, the best practise is to use DOMXPath from the search criteria when compared to Path .
	HTML name and ID	These properties are used to identify an HTML object

Technology type	Object properties	Description
	HTML inner text	The DOM innerText Property is used to set or return the text content of a specified node and its descendants
	HTML tag	HTML tags are like keywords that define the way web browser formats and displays the content. For example, if the captured text has an HTML code: <code><h3 class="search_results-title">Search results for "string package"</h3></code> , then enter h3 in the HTML tag field.
Microsoft Active Accessibility	Control type	This property is used only as a reference to ensure that the correct object is captured
	Path	It is a numeric representation of the position of a particular control in an application
	Name	This specifies a name of an element and works as an identifier
	ID	This specifies the ID of an element and works as an identifier
Java Technology	Control type	This property is used only as a reference to ensure that the correct object is captured
	Path	It is a numeric representation of the position of a particular control in an application
Microsoft UI Automation	Control type	This property is used only as a reference to ensure that the correct object is captured
	Path	It is a numeric representation of the position of a particular control in an application
	Name	This specifies a name of an element and works as an identifier
	ID	This specifies the ID of an element and works as an identifier
	IsFirst	This property enables the bot to detect the first object based on your search criteria instead of traversing the entire tree. You can use this property when an object does not have a unique Automation ID and the object hierarchy changes in the application.
Microsoft UI Automation (COM)	Control type	This property is used only as a reference to ensure that the correct object is captured.
	Path	It is a numeric representation of the position of a particular control in an application.
	Name	This specifies a name of an element and works as an identifier.

Technology type	Object properties	Description
	ID	This specifies the ID of an element and works as an identifier.

The bot uses the selected properties to identify the object control at runtime.

- a) Verify that the **Control Type** matches your intended object.

For example, when capturing a table from a website, ensure the **Control Type** and **HTML Tag** values are **Table**.

If the **Control Type** does not match your intended object, recapture the object control.

- b) Select and assign values to the object properties that you want to include in the object search.

For a more reliable bot, we recommend that you select only the properties that have static values (such as **Name**, **Class**, **Type**, **HTML ID**, and **DOMXPath**), and deselect the properties that have dynamic values (such as **HTML Href**, **Path** or **Value**), which are subject to change and cause bot errors.

It is a best practice to use the wildcard character (*) or variable in object property values to search for objects whose properties are dynamic and changes frequently.

9. Select the **Action** from the drop-down list.

For a full list of possible actions by object, see [Actions performed on objects captured with Universal Recorder](#) on page 2804.

- If you record a click and keystrokes in a text box with a **Control Type** of `Password text`, the **Recorder** does not capture the keystrokes entered into the field. Instead, the action selects the **Set text** option and offers options to securely input the password. We recommend that you store the password in the Credential Vault and insert it into the action as a credential.

See [Credentials and credential variables in the Bot editor](#) on page 2254.

If you navigate to the text box using the TAB keystroke instead of a click in an MSAA or SAP application, the **Recorder** is able to identify fields with a **Control Type** of `Password text`.

- If the selected **Action** supports background processing, a **Run in the background** option appears.

See [Background processing](#) on page 2164.

10. Optional: Enter a value in the **Keep trying for (seconds)** field to specify the number of seconds the bot must wait for the object control to appear on the application window.

We recommend setting a delay time when using the Set text action to enter keystrokes into a text field.

Note: The timeout specified for the bot to wait for the control to appear on the application window applies only if the window in which the control is present exists. The Recorder first looks for the application window and only then searches for the object inside that window. The default time to search for the window is 30 seconds. Hence, even if you specify the wait time as 5 seconds, it still waits for 30 seconds by default if the window does not exist.

We recommend that you first use the **If > Window exists** condition, specify a wait time of zero second and ensure that the application window exists. If the window exists then use the Recorder, specify a wait time of 5 seconds, and run the bot to detect the object.

11. Optional: Assign the output to a variable.

The Control Room suggests a descriptive default variable name based on the action you selected in step 8. For example, if you selected **Get property**, the suggested output variable is `PropertyValue`. If you create several output variables, subsequent variable names are appended with a `-1` to avoid duplication.

12. Click **Save**.

The captured images are not added as dependencies and will not be displayed in the dependencies list when you check in your bot.

Link an object to a supporting anchor

Note: You can use object anchoring in Microsoft Active Accessibility, Microsoft UI Automation, or Java applications.

At runtime, if the bot cannot reliably identify an object, link it to a nearby object (such as a link or button) that is easier for the bot to find:

1. Open the **Capture** action.
2. Click the **Anchor** tab.
3. Click **Capture anchor**.

The browser or application window activates with the main object highlighted (the object that you previously captured). A dialog box appears, verifying whether the action has correctly identified the main object.

4. If the correct object is highlighted, click **Yes, Select anchor**.

Otherwise, click **No, I need to correct it** to select the correct object.

5. Select a nearby object to the target object that is easier for the bot to find.

The object is highlighted with an anchor icon on the right of the object.

6. Click **Save**.

Capture using specific technology

In some applications, the **Capture** action might not work accurately if the technology for capturing is selected automatically. In such cases, based on the type of application that you want to automate, you can select a specific technology and use the **Capture** action to capture using that technology.

Using the Capture action

To select a specific technology, click the drop-down next to **Capture object**.

You can select a specific technology and automate the following applications:

- Automate web applications that have nested iFrames with the same frame source or different frame sources.
- Capture and automate objects on applications where automatic selection of technology might not capture accurately.

Note: When you capture using a specific technology, the type and the number of object properties differ.

- Automate all objects and controls on the Google Chrome and Microsoft Edge browsers for local setting pages.

Note: This functionality is supported for Google Chrome and Microsoft Edge browsers.

Technology types

You can capture objects with the following technologies:

- Microsoft Active Accessibility (MSAA)
- Microsoft UI Automation
- Microsoft UI Automation (COM)

Microsoft Active Accessibility (MSAA)

Microsoft Active Accessibility is a legacy accessibility technology that was introduced as a platform add-in for Windows 95. MSAA is designed to help Assistive Technology (AT) products interact with standard and custom user interface elements of an application and also to access, identify, and manipulate an application's UI elements. MSAA is based on the Component Object Model (COM), which defines a mechanism for applications and operating systems to communicate. To know more about the most commonly used properties in this technology, see [Using the Capture action](#) on page 2818.

Microsoft UI Automation

Microsoft UI Automation is an accessibility framework for Microsoft Windows, and it is available on all operating systems that support Windows Presentation Foundation (WPF). UI Automation provides programmatic access to most user interface elements on the desktop, enabling AT products such as screen readers to provide information about the UI to end users and to manipulate the UI by means other than standard input. To know more about the most commonly used properties in this technology, see [Using the Capture action](#) on page 2818.

Microsoft UI Automation (COM)

Microsoft UI Automation (COM) runs on unmanaged code and delivers automation faster than UI Automation. You can capture the following controls using the Microsoft UI Automation (COM) technology:

- Button
- Calendar
- Check box
- Client
- Combo box
- Label

- Link
- List view
- Menu
- Page Tab
- Password text
- Radio button
- Slider
- Table
- Text box
- Tree

When you select this technology to capture an object on an application, if that object is not supported for the technology, that is indicated by a gray highlight around the object.

Note: Microsoft UI Automation (COM) provides a search criterion (property) called **Automation ID**, which is unique to this technology.

Automate applications running on remote machines

Sometimes business applications run on remote machines and are accessed over VMware Horizon VDIs. You can automate these business applications using our native Remote Agent installed over a VMware VDI device.

Automate applications accessed over VMware

Our native Remote Agent enables secure communication between VMware VDI and the Bot Agent. It provides object level information for automation creation and play back thus enhancing the automation coverage for new use cases while providing a reliable native desktop user experience.

VMware-based automation is supported for all the VMware protocols such as: VMware Blast, PCoIP, and Microsoft RDP. This eliminates the need for any security exceptions by IT Administrators.

Prerequisites

Before you automate, you must install and run the Remote Agent on VMware VDI.

Note: To automate web pages using HTML technology, you must enable the Google Chrome and Microsoft Edge extensions .

Supported applications

VMware-based automation supports the following types of applications:

- Web applications
- Java applications
- Windows applications

Supported technologies

VMware-based automation supports object detection on the applications built using the following technologies:

- Microsoft Active Accessibility (MSAA)
- Microsoft UI Automation
- Java
- HTML - Chrome, Edge, Edge with IE mode

Known behavior

- You can only automate applications running inside VMware VDI using the **Capture** action.
- You can only capture applications running over VMware VDI in full screen mode.

Note: Ensure that you launch the VMware VDI from the VMware Horizon Client.

- If you have multiple monitors with full screen mode, then the left monitor must be your primary monitor.
- Anchor capture is currently not supported.
- Microsoft UI Automation (COM) technology is currently not supported.
- SAP technology is currently not supported.

Automate right-click action on objects hidden behind runtime window

Sometimes the objects that you want to automate appear behind the bot runtime window. In such cases, the window is minimized and then reactivated after the action is executed enabling you to successfully automate such objects.

When you perform a right-click action on a browser window, the context menu opens. When you try to click any option in this menu, it disappears because after you execute the right-click action, the active browser window changes to a runtime window. As a result, the context menu closes and the bot fails. To automate such scenarios, perform this procedure.

1. Create a window variable.
2. In the **Name** field, enter `RuntimeWindow`.
3. Select a window and in the **Window title** field, enter `Bot running*` and save the updates.
4. From the **Actions** pane, double-click or drag the **Window > Minimize** action.
5. In the **Window** field, select the variable `RuntimeWindow`.
6. Click **Start recording**.
7. From the **Recorder** window, select the specific browser window.
8. In the **Window** field, select the specific browser window.
9. Execute the **Right click** action on the specific browser page.
10. Select any option from the context menu.
11. From the **Actions** pane, double-click or drag the **Window > Restore** action.
12. In the **Window** field, select the variable `RuntimeWindow`.
13. Save and run the bot.

Recorder actions supported in various SAP versions

Review the information about the various actions of the Recorder package that are supported with Automation 360 and which SAP GUI versions support them.

Control name	Automation 360 supported action	SAP Logon 730 (Patch 15)	SAP Logon 740 (Patch 19)	SAP Logon 750 (Patch 10)	SAP Logon 760 (Patch 5)	SAP Logon 770 (Patch 6)
Text box	Set text	Yes	Yes	Yes	Yes	Yes
(It includes controls such as: GuiTextField, GuiTextField, GuiOkCodeField, GuiShell:TextEdit, GuiTextEdit, and GuiPasswordField)	Append text	Yes	Yes	Yes	Yes	Yes

	Double-click	Yes	Yes	Yes	Yes	Yes

REST Web Service package

Use the actions in the REST Web Service package as methods (DELETE, GET, PATCH, POST, or PUT) to send requests to and receive responses from an API.

Working with REST Web Service actions

Provide the following information to send a REST request and receive a response. Not all parameters are required for all methods.

- **Enter the URI:** A unique address for an API resource.
- **Proxy configuration:** To set the proxy, select the **System** or **Custom** tab from Proxy configuration.

Option	Description
System	System proxy is the proxy configured on the bot runner machine where the bot is running. If this option is selected, the Bot Agent uses the system proxy.

Option	Description
Custom	<p>This option allows you to configure custom proxy settings within the actions of REST Web Service. For example, if a REST API is required to be routed through a different proxy other than the system proxy, you can select the Custom option and provide proxy details within the REST actions.</p> <p>Provide the following details:</p> <ul style="list-style-type: none"> • Host: The host name or IP address of the proxy • Port: The port number of the proxy • Username (Optional): The username used for the proxy authentication • Password (Optional): The password used for the proxy authentication <hr/> <p>Note: If the proxy to be configured is authenticated proxy, then you must provide authentication credentials in the Username and Password fields.</p> <hr/> <p>For Host, Port, Username, and Password fields, choose from Credential, Variable, or Insecure string tab :</p> <ul style="list-style-type: none"> • Credential: Use a value available in the credential vault. • Variable: Use a variable that stores a credential value in a user-defined variable. • Insecure string: Manually specify the value that you want to use.

- **Authentication Mode:** There are three supported authentication modes:
 - **No Authentication:** Use this option to access the endpoints that does not require authentication to access their servers.
 - **Basic:** Basic is the simplest way to authenticate users. When you select this option, you will enter the username and password. This technique uses a header called Authorization, with a base64 encoded representation of the username and password entered.
 - **Logged-in AD User:** Active Directory (AD) users that are authorized to access the related API are authenticated through AD. No credentials are required in the request.
 - **Windows NT LAN Manager (NTLM) Authentication (AD User):** A challenge/response authentication method that allows clients to provide their user name and password as encrypted credentials or plain text. We recommend that you use credentials that are stored in the Automation Anywhere Credential Vault.
 - **OAuth2 - Control Room managed:** When you integrate OAuth with the Control Room, you can centrally manage and securely store tokens that are used to authenticate with third-

party providers. You must configure the web service and make note of the authentication details (such as client ID, client secret, authorization URL, and so on) to use the OAuth connection in the Control Room. For more details, see [Integrate OAuth with Control Room](#) on page 1824

The following video shows how to use OAuth connection in REST Web Service:

- **Header:** Not all methods require a header. Headers represent the metadata associated with the request.
- **Content type:** When a header contains a content type, it defines the content negotiation between the client and the server. REST Web Service actions support the following content types:
 - `application/x-www-form-urlencoded`: Encode the parameters in the URL.
 - `JSON (application/json)`: Enter a JSON request body.
 - `XML (application/xml)`: Enter an XML request body.
 - `Text (text/plain)`
 - `XML (text/xml)`
 - `HTML (text/html)`
 - `multipart/form-data`: Send binary data, in most cases for uploading files to the server.
- **Add substitution:** Allows you to enter variables in the REST request body. A variable is a symbolic representation of data, and it enables you to access a value without having to enter it manually wherever you need it. For example, consider the following REST body request:

```
{
  "name": "{{name}}",
  "email": "{{email}}",
  "status": "Active"
}
```

In the above request body, you can replace the variables enclosed within double braces by clicking **Add substitution** and adding the required values.

- **Advanced options:**
 - **Capture failure response:** Select the check box to capture the failure response except for the `Success/Ok` response. The failure response details are captured in the response body.
 - **Allow insecure connection when using https:** Select the check box to allow insecure connection when using https.
- **Wait for action to complete:** You can set a time-out value when you send a REST request and receive a response. When performing actions such as POST, PUT, DELETE, PATCH, and GET, in the **Wait for action to complete** field, you can specify the wait time (in milliseconds). By default, the wait time is 60000 milliseconds.
- **Output variable:** The response output is captured in a dictionary variable. A dictionary variable is a key-value pair. Use the response header name as key to return the header value, or "Body" as the key to return the response body.

Note: The response key with its value is available in the dictionary variable to display the response status of the REST API.

To obtain a list of the header names for the API resource, perform these steps:

1. Insert a **Loop** action after the REST Web Service action.
2. Select the **For each key in the dictionary** iterator.

3. In the **Dictionary variable** field, select the variable that holds the REST Web Service action output.
4. Assign the value of each key to `$prompt-assignment$`.
5. Insert a Log To File action.
6. Provide the file path to a text file to hold the list of header names.
7. Insert `$prompt-assignment$` in the **Enter text to log** field.
8. Select the **Overwrite existing file** option.
9. Click **Save**.

When you run the bot, it prints the header names from the API resource to the selected file.

Passing values securely

You can securely pass values from the Credential Vault to the web service by specifying the locker, credential, and attribute in the following supported action fields:

- URI
- Custom headers
- Body: For the `application/x-www-form-urlencoded` content type, click **Add parameter** to select the value from the Credential Vault.

For all other content types, select the **Select credential as parameters** option and click **Pick**.

Actions in the REST Web Service package

Action	Description
Delete method	Removes the resource that is identified by the URI.
Get method	<p>Retrieves information identified by parameters included in the URI. There is no Content type for the GET method because all the parameters are passed as part of the URI.</p> <p>Limitations and characteristics of the GET method include the following:</p> <ul style="list-style-type: none"> • URI length is limited to 2048 characters. • All parameters are passed in the URI. • The GET method exposes data that is in the URI, making it less secure than the POST method. • GET does not change any data, making it safe for all users regardless of authorization. <p>See Using the Get method on page 2838.</p>
Patch method	Modifies the resource that is identified by the URI.

Action	Description
Post method	<p>Creates a new resource in the URI.</p> <ul style="list-style-type: none"> Parameters are passed in request body. There is no limit on length for a request body. <p>See Using the Post method on page 2840.</p>
Put method	<p>Updates or replaces a resource based on parameters passed in the URI or body. See Using the Put method on page 2843.</p>

Proxy support

If your device is configured with a proxy, all outbound requests from this package are routed through the proxy server. See [Connect Bot Agent to a device with a proxy](#) on page 1293.

Related tasks

[Example of building a bot that uses credential variables](#) on page 2258

Securely pass values to a bot using credential variables to automate the process of logging in to a bank website.

Related reference

[Credentials and credential variables in the Bot editor](#) on page 2254

Use credentials when building bots to pass sensitive information such as passwords and account numbers. Using credentials separates the sensitive information from the bots and Bot Runners, which reduces the risk of data spillage or unauthorized user access.

[Rest Web Services package updates](#) on page 895

Review the updates in released versions of the Rest Web Services package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using the Get method

Use the **Get method** actions from the REST Web Service package to retrieve or get the information identified by parameters included in the URI .

This example uses endpoints from the Swagger Petstore sample API ([Petstore](#)) to demonstrate using Get method action to retrieve data from the Petstore database.

Note: GET method action does not take any request body.

1. Create a new .
 - a) Log in to your instance of the .
 - b) On the left panel, click **Automation**.
 - c) Click **Create new > Bot**.
 - d) In the **Create Task Bot** window, enter the name.
 - e) Accept the default folder location: \Bot.s\
To change the default storage location, click **Choose** and follow the prompts.

f) Click **Create and edit**.

2. Use the **Get method** action to retrieve a list of all the available pets.

a) Double-click or drag the **REST Web Services > Get method** action.

The screenshot shows the Test-bot interface with a workflow and the configuration for the REST Web Services: Get method action.

Workflow:

- Start
- 1. REST Web Services: Get method... request for URI 'https://petsto...
- 2. Log to file \$Output{Body}\$ to 'C:\TempL...
- End

REST Web Services: Get method configuration:

- The GET method gets (reads) the information (in the form of an entity) that is identified by the Request URI.
- Required bot agent version: 20.11 or above
- URI: Enter the URI
 - URI: `https://petstore.swagger.io/v2/pet/findByStatus` (marked with 'b')
 - Example: `https://domainname.com/resource/search?param1=value1¶m2=value2`
- Select credential as URI: (None selected)
- Authentication Mode: No Authentication (marked with 'c')
- Header: Custom headers (optional)

Enabled	Name	Value
No headers		
- Advanced options:
 - Capture failure response
 - Allow insecure connection when using https
 - Warning: Transferred data may be visible to attackers
- Wait for action to complete (in milliseconds): 60000
- Assign the output to a variable:
 - Multiple variables: Dictionary
 - Output (marked with 'd')
 - Use response header name to fetch header value and 'Body' as key to fetch body of response

b) Enter the following URI:

```
https://petstore.swagger.io/v2/pet/findByStatus?status=available
```

c) Under **Authentication Mode** drop-down, select **No Authentication** as this endpoint does not require authentication.

Note: Typically endpoint requires authentication to ensure that only authorized applications are able to access the data. Select an appropriate authentication mechanism to allow access to the endpoint you want to access.

d) Create the variable **Output** in the **Assign the output to a variable** field. For more information on creating a variable, see [Create a variable](#) on page 2246.

3. Insert a **Log to file** action to see the response body.

a) Double-click or drag the **Log to file** action.

b) Provide the file path to a text file.

c) In the **Enter text to log** field, enter `$Output {Body} $`.

4. Click **Save** and then click **Run**.

The bot retrieves the response body and saves it to the text file.

Note: You cannot use the download API endpoints to download an exported bot or file in the REST Web Service package.

- [Using the Post method](#) on page 2840
- [Using the Put method](#) on page 2843
- [Upload file with Put method](#) on page 2844

Using the Post method

Use the **Post method** actions from the REST Web Service package to create new resources in the URI.

This example uses endpoints from the Swagger Petstore sample API ([Petstore](#)) to demonstrate using Post method action to add data to the Petstore database.

1. Create a new .
 - a) Log in to your instance of the .
 - b) On the left panel, click **Automation**.
 - c) Click **Create new > Bot**.
 - d) In the **Create Task Bot** window, enter the name.
 - e) Accept the default folder location: `\Bots\`
To change the default storage location, click **Choose** and follow the prompts.
 - f) Click **Create and edit**.
2. Use the **Post method** action to send data to a server. In this example, a new pet is added to the store.

- a) Double-click or drag the **REST Web Services > Post method**

action.

- b) Enter the following URI:

`https://petstore.swagger.io/v2/store/order`

- c) **Proxy Configuration:** Do one of the following:

- **System:** Under **Authentication Mode** select the authentication. In this example, select No Authentication as this endpoint does not require authentication.

Note: Typically endpoint requires authentication to ensure that only authorized applications are able to access the data. Select an appropriate authentication mechanism to allow access to the endpoint you want to access.

- **Custom:** This option allows you to configure custom proxy settings within the actions of REST Web Service. For more information, see [REST Web Service package](#) on page 2834 .

- d) Select the **Content type** that indicates in which format the data is sent to. An incoming request can have an entity attached to it. The Content type determines the type of the request. Some common Content types include such as: application/x-www-form-urlencoded, JSON (application/json), and XML (application/XML). In this example, select JSON (application/json), copy and paste the following into the **Custom parameters** field:

```
{
  "id": 0,
  "petId": 0,
  "quantity": 0,
  "shipDate": "2022-04-20T22:08:11.977Z",
  "status": "placed",
  "complete": true
}
```

- e) **Add substitution:** Allows you to enter variables in the REST request body. A variable is a symbolic representation of data, and it enables you to access a value without having to enter it manually wherever you need it. For example, consider the following REST body request:

```
{
  "name": "{name}",
  "email": "{email}",
  "status": "Active"
}
```

In the above request body, you can replace the variables enclosed within double braces by clicking **Add substitution** and adding the required values.

- f) Enter a time in milliseconds for the action to complete. You can leave it to the default 60,000.
- g) Create the variable `Output` in the **Assign the output to a variable** field. For more information on creating a variable, see [Create a variable](#) on page 2246.
3. Insert a **Message box** action to see the response body.
- a) Double-click or drag the **Log to file** action.
- b) In the **Enter the message to display** field, enter `$Output {Body} $`.
4. Click **Save** and then click **Run**.
The bot displays the response in the message box.

- [Using the Get method](#) on page 2838
- [Using the Put method](#) on page 2843
- [Upload file with Put method](#) on page 2844

Using the Put method

Use the **Put method** actions from the REST Web Service package to update or replace existing resource.

This example uses endpoints from the Swagger Petstore sample API ([Petstore](#)) to demonstrate using Put method action to update data to the Petstore database.

1. Use the **Put method** action to update the pet name to "Pluto" and pet status to "sold".

- a) Double-click or drag the **REST Web Services > Put method** action.
- b) Enter the following URI:

```
https://petstore.swagger.io/v2/pet
```

- c) Open the log file saved in [Using the Get method](#) on page 2838 and copy the Pet ID of the first entry.
- d) Copy and paste the following into the **Custom parameters** field, replacing the text in the angle brackets with the value that you copied from the file:

```
{  
  "petId": 0,  
  "name": "Pluto",  
  "status": "sold"  
}
```

- e) Insert the variable `Output` in the **Assign the output to a variable** field.
2. Move the **Message box** action below the **Put method** action:
 - a) Double-click or drag the **Message box** action.
 - b) In the **Enter text to log** field, enter `$Output {Body} $`.

3. Click **Save** and then click **Run**.

The bot retrieves the response body and prints it to the Message box. A successful response includes `"name": "Pluto", "status": "sold"`.

- [Using the Post method](#) on page 2840
- [Using the Get method](#) on page 2838
- [Upload file with Put method](#) on page 2844

Upload file with Put method

Use the **Put method** action in the REST Web Service package to upload a file or text.

This example uses endpoints from the Petstore sample API ([Petstore](#)) to demonstrate uploading a new file or text using a multipart/form-data.

1. Use the **Put method** action in conjunction with an API that allows uploading a file.

- a) Double-click or drag the **REST Web Services > Put method** action.
- b) Enter the following URI:

```
https://petstore.swagger.io/v2/pet/112/uploadImage
```

c) From the **Content type** drop-down, select **multipart/form-data**.

The screenshot shows the configuration of the REST Web Services action. The URI is entered as `https://petstore.swagger.io/v2/pet/112/uploadImage`. The content type is set to `multipart/form-data`. Two parameters are defined:

Enabled	Name	Type	Value
Yes	file	File	"C:\Temp\icon.png"
Yes	additionalMetadata	Text	"*****"

- d) Add the `file` parameter and provide the path of the file to be uploaded.
- e) Add any other required parameters. For instance, this API takes `additionalMetadata` (for example, "hello"), which is a text input parameter. The additional parameter will also be uploaded.

2. Assign the output to a variable, for example, `Test123`.

1. REST Web Services: Post met... request for URI "https://petsto..."

2. Message box <Test123(Body)>

Allow insecure connection when using https
Warning: Transferred data may be visible to attackers

Wait for action to complete (in milliseconds)
60000 (x)

Increase this value if POST action times out

Assign the output to a variable
Multiple variables Dictionary (x)

<Test123 (x)

Use response header name as key to fetch header value and 'Body' as key to fetch body of response

3. Print the output in a message box.

Message box

Displays a message box
Required bot agent version: 20.11 or above

Enter the message box window title
Automation Anywhere Enterprise Client (x)

Enter the message to display
\$Test123(Body)\$ (x)

Scrollbar after lines
30 (x)

Close message box after

1. REST Web Services: Post met... request for URI "https://petsto..."

2. Message box \$Test123(Body)\$

Delete method

Use the **Delete** method action in the REST Web Service package to remove a resource that is identified by the URI.

Patch method

Use the **Patch** method action in the REST Web Service package to action modify the resource that is identified by the URI.

Salesforce package

Salesforce is a cloud-based platform that provides software and services to create relevant customer experiences. Use the bot actions developed for the Salesforce package to automate Salesforce processes.

Salesforce is based on a multi-tenant architecture with benefits such as API integration, configuration, scalability, free capacity, platform support, and more. The Salesforce package uses the Lightning Platform APIs to integrate Automation 360 with Salesforce. RPA developers need to authenticate to build automation processes in Salesforce. After authentication, with the Salesforce Connected App, you can upload or download files, perform CRUD (Create/Insert, Read, Update/ Upsert, Delete) operations on Objects (Salesforce stores data as Objects), and query using SOQL.

The following video shows the initial authentication and command actions from Automation 360:

Two types of objects are available in Salesforce, Standard Objects and Custom Objects. Standard Objects include the configuration and default data types. Custom Objects are the objects that are defined according to business requirements. In this topic, sample CRUD operations will be based on the Case Object, which is a Standard Object. A Case Object is typically used to gather customer data (queries, feedback, or problems). All the samples are based on manipulating the fields of the Case Object. For more information on the Case Object, see [Salesforce Case object](#). All the CRUD operations are initiated from the Automation 360 side and will update data on the Salesforce side.

Related reference

[Salesforce package updates](#) on page 896

Review the updates in released versions of the Salesforce package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Salesforce Authentication action

Salesforce Authentication is the first command action that you need to call to get authenticated with Salesforce.

Authenticate access to Salesforce by getting the authentication parameters from the Salesforce connected app and using them in Automation 360.

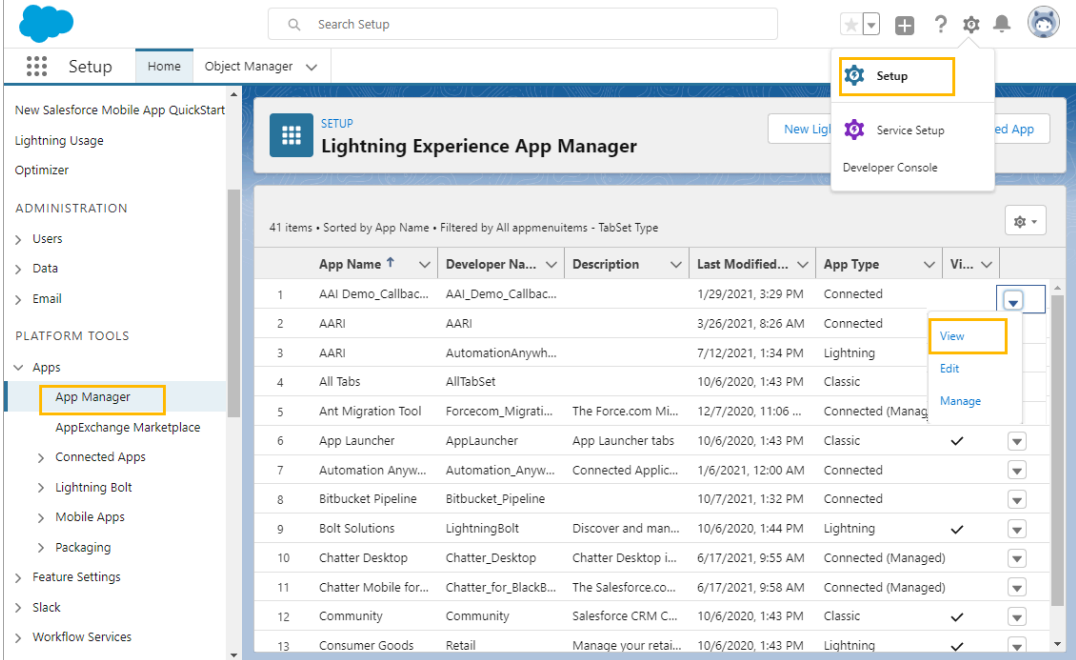

Note: Recently, Salesforce implemented the following: OAuth 2.0 Username-Password Flow Blocked by Default in New Orgs. Ensure you **allow** these flows in your Salesforce environment to use the Salesforce package. See, [OAuth and OpenID Connect Settings](#)

You can use different connection methods to connect to Salesforce:

- **OAuth2 - Client Credentials:** Use this connection method by providing the Salesforce account credentials. You need a Salesforce username and password to establish a connection.
- **Control room OAuth connection:** Use this connection method by creating an OAuth connection and storing it in the Control Room.

1. Log in to the Control Room.
2. Create a new bot or modify an existing bot. For more details, see [Create your first bot](#) on page 1429.
3. From the Actions pane, select **Salesforce > Authentication** and place it under the **Start** of the bot flow.

4. In the **Authentication Type** field, select the authentication method from the drop down.
5. To view client ID and client secret details for **OAuth2 - Client Credentials** authentication, complete the following steps:
 - a) Log in to the Salesforce Enterprise Edition (Lightning Experience - [Salesforce Login](#)), click , and select **Setup** on your connected app. For more information about creating a new connected app, see [Salesforce Connected Apps](#).
 - b) In the Lightning Experience App Manager, click **App Manager**.

The screenshot shows the Salesforce Setup interface. The left sidebar contains a navigation menu with 'App Manager' highlighted. The main content area is titled 'Lightning Experience App Manager' and displays a table of 41 items. The table has the following columns: App Name, Developer Name, Description, Last Modified, App Type, and Visibility. The 'View' button for the first item is highlighted.

	App Name	Developer Na...	Description	Last Modified...	App Type	VI...

- c) Click the down arrow next to app name and select **View**.
The **Manage Connected Apps** screen appears. For more information about managing connected apps, see [Salesforce Manage Connected Apps](#).
- d) Click **Manage Consumer Details**.
- e) Click **Copy** that corresponds to **Consumer Key**.

- f) Click **Copy** that corresponds to **Consumer**

Secret.

The screenshot shows the Salesforce interface for a Connected App named "AAI Demo_Callback Connected App". Under the "Consumer Details" section, there are two rows of information:

- Consumer Key:** A masked value (3M...) with a yellow box around the "Copy" button.
- Consumer Secret:** A masked value (9D684...) with a yellow box around the "Copy" button.

Below this is the "Staged Consumer Details" section, which includes a description: "Generate staged values for the consumer key and secret. When you apply the staged values, they replace the original consumer details." It contains two rows:

- Staged Consumer Key:** Not generated
- Staged Consumer Secret:** Not generated

At the bottom right of the "Staged Consumer Details" section, there are three buttons: "Generate", "Apply", and "Cancel".

6. To connect using OAuth2 - Client Credentials, complete the following steps:
- In the **Client ID** field, paste the **Consumer Key** copied from the Salesforce Connected App. In this illustration **Insecure string** is used, while you can use **Credential** or **Variable** options for better security.

- b) In the **Client Secret** field, paste the **Consumer Key** copied from the Salesforce Connected App.

Salesforce: Authentication 📄

Salesforce Authentication is the first command action that you need to call to get authenticated with the Salesforce.

Required bot agent version: 21.222 or above

Authentication type
OAuth2 - Client Credentials ▼

Client ID
Credential Variable Insecure string

a " [redacted] 🟢 (x)

Client secret
Credential Variable Insecure string

b " [redacted] 🟢 (x)

Salesforce username
Credential Variable Insecure string

c " [redacted]@aasd-foundation-int.com 🟢 (x)

Salesforce password
Credential Variable Insecure string

d " [redacted] 🟢 (x)

Environment
 Production
 Sandbox

API version
" 55 🟢 (x)

Session name
" Default (x)

Save the outcome to a variable (optional)
Multiple variables Dictionary

str-authresponse ▼ (x)

e.g. 'Authorization' as Credential type, 'InstanceUrl' as String type

- c) Enter the Salesforce username.
- d) Enter the Salesforce password.

Note: You can use one of the following options to specify the **Client ID/Client secret/Salesforce username/ Salesforce password**:

- **Credential:** Enables you to use a value in the Credential Vault that contains information about the Client ID/Client secret/salesforce username/salesforce password.
- **Variable:** Enables you to use a credential variable that contains information about the Client ID/Client secret/salesforce username/salesforce password.
- **Insecure string:** Enables you to enter the Client ID/Client secret/salesforce username/salesforce password manually.

-
- e) Select **Production** to log into a live environment or **Sandbox** to log into a testing environment.
7. To configure a **Control room OAuth connection** in Salesforce, complete the following steps:
- a) Complete step 1 to step 5 in [Create OAuth connection](#) on page 1827.
 - b) Log in into Salesforce as an Admin and navigate to **App Manager** to create a new connected app.
 - c) Enter the following details:
 - Connected App name
 - API name
 - Contact email
 - Select the **Enable OAuth Settings** check box.
 - Add the Callback URL from [Create OAuth connection](#) on page 1827 as an authorized redirect URI.
 - Select the **OAuth scopes** as `Manage user data via APIs (API)` and `Perform requests at any time (refresh_token, offline_access)`.
 - Select the **Authorization Code** and **Credentials Flow** check box.
 - d) Click **Save**.
 - e) Click **Manage Consumer Details**. Copy the client key and secret.
 - f) Go to [Create OAuth connection](#) on page 1827 and complete the remaining steps to create an OAuth connection with the above details.
8. To connect using **Control room OAuth connection**, pick a Salesforce OAuth connection you have created and stored in the Control Room. For more details, see [Integrate OAuth with Control Room](#) on page 1824.
9. Enter the API version. You can find the API version in your Salesforce Enterprise Edition setup. For more details, see [Find Salesforce API version](#).
10. Enter **Default** as the Session name.
11. Create either a **Multiple** or **Dictionary** variable to store the response. You can do one of the following:
- The authentication command returns a dictionary with 2 key-value pairs. `Authorization` (credential type) and `InstanceUrl` (String type). The `Authorization` is hidden, but you

will be able to read the `InstanceUrl`. For example, you can use a message box to print of the value of `,$str_Authresponse{InstanceUrl}$`, this returns the Salesforce URL.

- You can select Multiple variable as shown below and map to a credential variable and a string variable as keys.

Save the outcome to a variable (optional)

Multiple variables | Dictionary

Mapped variables

Key	Map to variable
Authorization	Authorization
InstanceUrl	instanceUrl

Add variable mapping

e.g. 'Authorization' as Credential type, 'InstanceUrl' as String type

Authorization returns a token, which is hidden as it is a credential type, this token can be passed directly in the [Rest Web Services](#) command.

- Click **Run** to save and run your bot. Once authenticated, you will be able to use the token to call other Salesforce API services.

Salesforce Insert record action

Use the Salesforce Insert record action to insert a new record into a Salesforce object along with values of the fields that should be mapped to the object's fields.

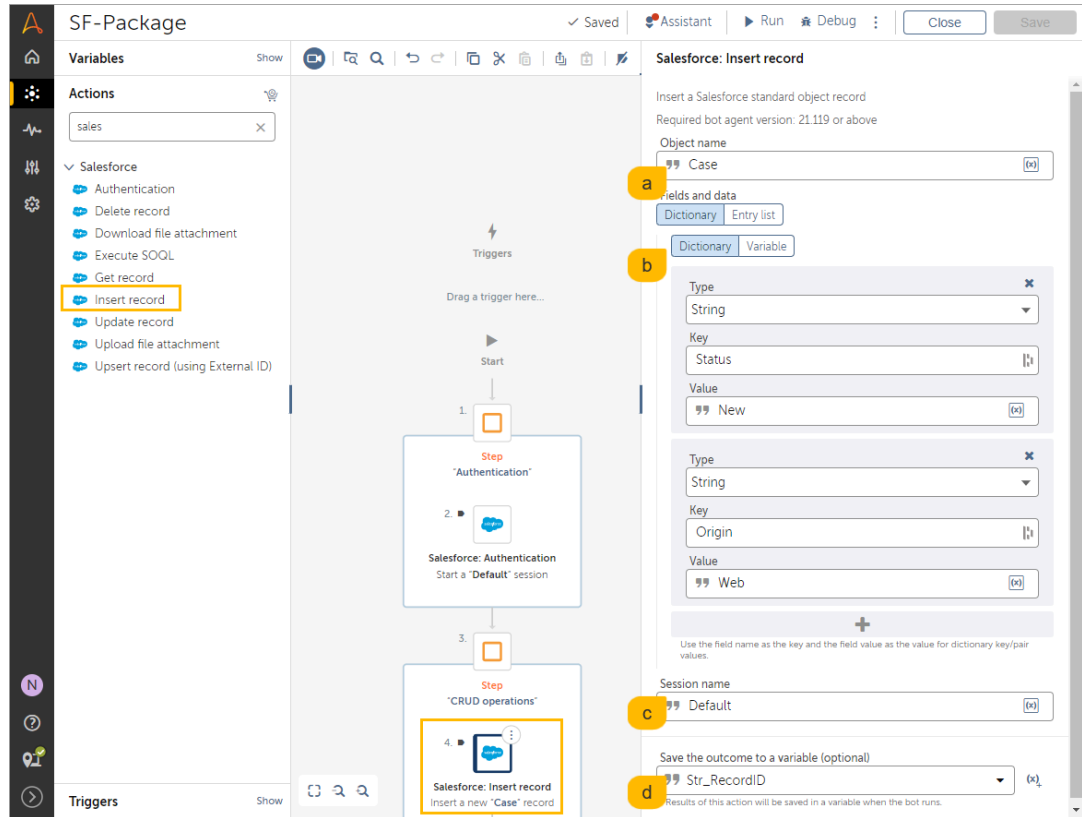

Note: Ensure that you are authenticated before calling any Salesforce action. For more information about authentication, see [Salesforce Authentication action](#) on page 2846.

In this tutorial, you will insert a few fields into a Salesforce object by using the **Insert record** action.

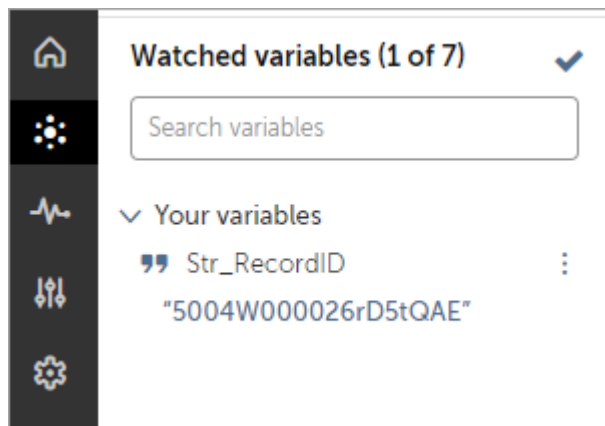

- From the **Actions** pane, select **Salesforce > Insert record** and place it in the canvas.
- Enter the following fields:
 - Enter the **Object name**, for example, Case.

Note: For Salesforce Custom objects, ensure that you provide the API name instead of the Display name of the object. For example, provide API name: `AAIRPA__Salesforce_Connection__c` and not the display name: [Salesforce Connection](#) " For more information on how to find the API name, see <https://help.salesforce.com/s/articleView?id=000327123&type=1>.

- Enter the **Fields and data** that you want to insert. Choose either **Dictionary** or **Entry list**. In this sample, **Dictionary** is selected and a few fields in Case object are modified. For example, Status is set to New and Origin is set to Web.

- c) Enter Default as the session name.
 - d) Save the outcome to a variable. For example, the object ID is saved to Str_RecordID.
3. Verify whether the value is inserted into Salesforce.
- a) Find the value of the Str_RecordID variable in the **Debug** mode.

- b) In Salesforce, go to the Case object with the record ID (for example, 5004W000026rD5tQAE) that you received as the response.

The screenshot shows the Salesforce Case record page for Case 00003444. The page is titled 'Case' and is located in the 'Object Manager' section. The case details are as follows:

Field	Value
Case Owner	Nirmal Mathimaran (Change)
Case Number	00003444 (View Hierarchy)
Contact Name	
Account Name	
Type	
Case Reason	
CaseCustomNumberField	
DateTime_Testing	
Currency_Testing	
CustomDateTime	
CustomDate	
Date_Testing	
Percent_Testing	
URL_testing	
Time_Testing	
TextArea_Testing	

The status is 'New' and the case origin is 'Web'. The page also shows a feed with no updates and a sidebar with navigation options like Details, Fields & Relationships, and Lightning Record Pages.

Verify whether the field's values match the input that you sent from Automation 360. For example, in this case, the Status is New and Case Origin is Web.

Salesforce Get record action

The Salesforce Get record action is used to read the fields of a Salesforce object.

Note: Ensure that you are authenticated before calling any Salesforce action. For more information about authentication, see [Salesforce Authentication action](#) on page 2846.

To read the field of a Salesforce object by using the **Get record** action, perform the following steps:

1. From the **Actions** pane, select **Salesforce > Get record** and place it in the canvas.
2. Enter the following fields:
 - a) Enter the **Object name**, for example, Case.

Note: For Salesforce Custom objects, ensure that you provide the API name instead of the Display name of the object. For example, provide API name: AAIRPA__Salesforce_Connection__c and not the display name: [Salesforce Connection](#) " For more information on how to find the API name, see <https://help.salesforce.com/s/articleView?id=000327123&type=1>.

- b) Enter the **Record ID** that you want to read. You will also be able to read data using the **External ID**. For more information on **External ID**, see [Salesforce Upsert record action](#) on page 2857.

The screenshot displays the Salesforce automation configuration interface. On the left, the 'Actions' sidebar lists various Salesforce actions, with 'Get record' highlighted. The central workspace shows a flowchart with the following steps: 1. Start, 2. Salesforce: Authentication (Start a 'Default' session), 3. Salesforce: Get record (Get a 'Case' record with ID '5...'), 4. Message box (\$SFDC_Res{Status}\$), and 5. End. The right-hand configuration panel for the 'Salesforce: Get record' action is detailed below:

- Object name:** Case
- Record ID / External ID:** 5004W000026rD5tQAE
- Fields and data (optional):** List, Variable. Type: String. Value at 0: Status.
- Session name:** Default
- Save the outcome to a variable:** Multiple variables, Dictionary. Variable name: SFDC_Res.

- c) Select **List** for the **Fields and data (Optional)** field. Enter all the fields that you want to read. In this sample, the field Status is read.
- d) Save the outcome to a variable. For example, the object ID is saved to SFDC_Res. Output is retrieved as a Dictionary that consists of the field name and field value. Field name is identical to the name specified in the Salesforce object. It is recommended to use the Debugger tool and watch the output variable to view the retrieved record.
3. Click **Run** to start the bot. You will be able to read the value of the field by simply printing the value in a Message box action. For example, in this sample, `$$SFDC_Res{Status}$` will print New

Salesforce Update record action

Update the fields of Salesforce Objects by using the Salesforce Update record action.

Note: Ensure that you are authenticated before calling any Salesforce action. For more information about authentication, see [Salesforce Authentication action](#) on page 2846.

To update a field in a Salesforce Object by using the **Update record** action, perform the following steps:

1. From the **Actions** pane, select **Salesforce > Update record** and place it in the canvas.
2. Enter the following fields:

The screenshot displays the Automation Anywhere interface for configuring a Salesforce automation. On the left, the 'Actions' pane shows 'Salesforce > Update record' selected. The central canvas shows a flow diagram with three steps: 'Salesforce: Authentication', 'Salesforce: Get record', and 'Salesforce: Update record'. The right pane shows the configuration for the 'Salesforce: Update record' action, including 'Object name' (Case), 'Record ID' (5004W000026rD5tQAE), and 'Fields and data' (Status: In progress).

- a) Enter the **Object name**, for example, Case.

Note: For Salesforce Custom objects, ensure that you provide the API name instead of the Display name of the object. For example, provide API name: AAIRPA__Salesforce_Connection__c and not the display name: [Salesforce Connection](#) " For more information on how to find the API name, see <https://help.salesforce.com/s/articleView?id=000327123&type=1>.

- b) Enter the **Record ID** that you want to update.
- c) In the **Fields and data (Optional)** field, select **Entry List**. Click **Add new field/value pair to update** and enter the **Field name** that you want to update and the **Field value (optional)** that you want the field to be updated with. For example, enter Status as **Field name** and In progress as **Field value (optional)** in **Fields and data**. You can also choose **Dictionary** and enter the values as a key/value pair.
- d) Save the outcome to a variable. For example, the object ID is saved to SFDC_Res.

- e) Enter the **Record ID** that you want to update.
3. To start the bot, click **Run**. You can verify the update by checking it in the Salesforce side. The following video shows the process:

Salesforce Delete record action

Delete records from Salesforce by using the Salesforce Delete record action.

Note: Ensure that you are authenticated before calling any Salesforce action. For more information about authentication, see [Salesforce Authentication action](#) on page 2846.

To delete a field of a Salesforce object, use the **Delete record** action.

1. From the **Actions** pane, select **Salesforce > Delete record** and place it in the canvas.
2. Enter the following fields:
 - a) Enter the **Object name**, for example, Case.

Note: For Salesforce Custom objects, ensure that you provide the API name instead of the Display name of the object. For example, provide API name: AAIRPA__Salesforce_Connection__c and not the display name: [Salesforce Connection](#) " For more information on how to find the API name, see <https://help.salesforce.com/s/articleView?id=000327123&type=1>.

- b) Enter the **Record ID** that you want to delete.

The screenshot displays the Automation Anywhere interface for configuring a 'Salesforce: Delete record' action. The left sidebar shows the 'Actions' pane with 'Salesforce > Delete record' selected. The central canvas shows a flow diagram with two steps: 1. 'Salesforce: Authentication' and 2. 'Salesforce: Delete record'. The 'Salesforce: Delete record' step is highlighted with a yellow box. The right-hand configuration panel for the 'Salesforce: Delete record' action is visible, showing the following fields:

- Object name for deletion:** Case (highlighted with a yellow box 'a')
- Record ID:** 5004W000026rD5tQAE (highlighted with a yellow box 'b')
- Session name:** Default

3. Click **Run** to start the bot. You will be able to verify the deletion by checking it on the Salesforce side. The following video shows the process:

Salesforce Upsert record action

Insert or update a record by using the Salesforce Upsert record action. The Upsert action uses a custom external ID as the key to identify a record.

Note: Ensure that you are authenticated before calling any Salesforce action. For more information about authentication, see [Salesforce Authentication action](#) on page 2846.

1. From the **Actions** pane, select **Salesforce > Upsert record (using External ID)** and place it in the canvas.

The screenshot displays the configuration for the 'Salesforce: Upsert record (using External ID)' action. The configuration panel includes the following fields and options:

- Object name:** Case
- External field name:** AAIRPA__CustomFieldForExternal
- External ID:** \$ExternalID\$
- Fields and data:**
 - Field 1:** Type: String, Key: Status, Value: New
 - Field 2:** Type: String, Key: Origin, Value: Email
- Session name:** Default
- Save the outcome to a variable (optional):** Dict_ExternalID-Insert

2. Enter the **Object name**, for example, Case.
3. Enter the field name that will store the ExternalID.

Note: In this sample, the ExternalID is generated by using the **Generate random string** action.

4. Enter the ExternalID generated.
5. Enter the fields that you want to update.
6. To verify, you can store the generated recordID in a variable. The following video demonstrates how to inserting fields to a record created in Salesforce.

7. To update a field by using the Upsert record action, from the **Actions** pane, select **Salesforce** > **Upsert record (using External ID)** and place it in the canvas.
8. Enter the **Object name**, for example, Case.

Note: For Salesforce Custom objects, ensure that you provide the API name instead of the Display name of the object. For example, provide API name: AAIRPA__Salesforce_Connection__c and not the display name: [Salesforce Connection](#) " For more information on how to find the API name, see <https://help.salesforce.com/s/articleView?id=000327123&type=1>.

9. Enter the same field name that will store the ExternalID.
10. Enter the same ExternalID to refer to the same record.
11. Enter the **Field Name** and new **Field Value** to update in **Fields and data**. You can also choose **Dictionary** and enter the values as a key/value pair.

12. To verify, you can store the outcome to a variable, for example, Dict_ExternalId-update.

Salesforce Execute SOQL action

To search your Salesforce data for specific information, run the Salesforce Object Query Language (SOQL) command from Automation 360 by using the Salesforce Execute SOQL action.

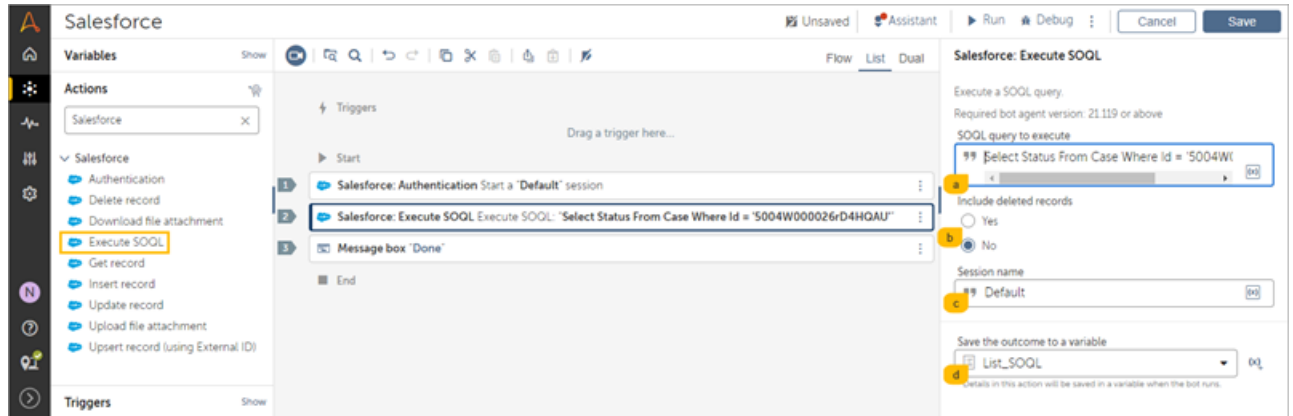

SOQL is similar to Structured Query Language (SQL) but is tailored for Salesforce data. For more information about SOQL, see [Salesforce Execute SOQL](#).

To get specific information from Salesforce data, execute a query from Automation 360.

To send an SOQL query to Salesforce by using the **Execute SOQL** action, perform the following steps:

Note: Ensure that you are authenticated before calling any Salesforce action. For more information about authentication, see [Salesforce Authentication action](#) on page 2846.

1. From the **Actions** pane, select **Salesforce** > **Execute SOQL** and place it in the canvas.

2. Enter the following fields:

- a) Enter the **SOQL query to execute**, for example, `Select Status From Case Where Id = '5004W000026rD4HQAU'`.

Note: For Salesforce Custom objects, ensure that you provide the API name instead of the Display name of the object. For example, provide API name: `AAIRPA__Salesforce__Connection__c` and not the display name: `Salesforce Connection`. For more information on how to find the API name, see <https://help.salesforce.com/s/articleView?id=000327123&type=1>.

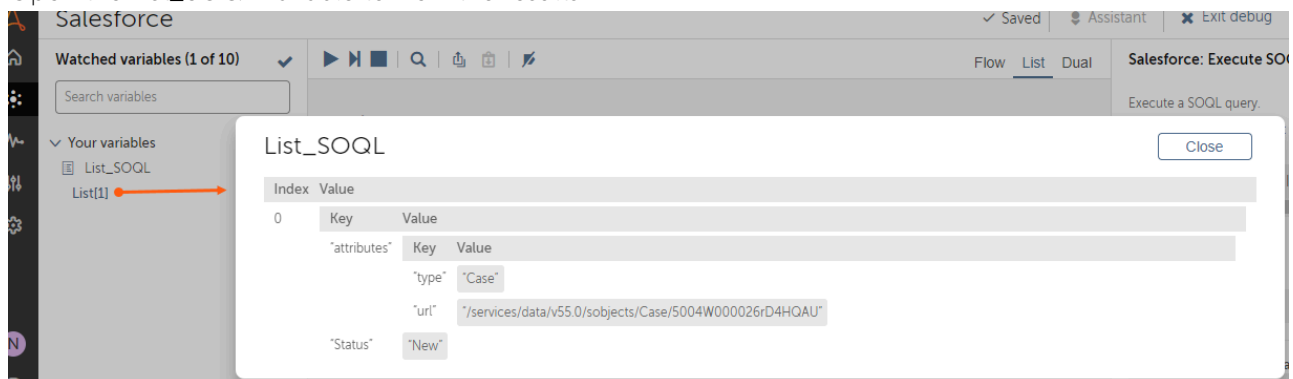

b) Select one of the following options:

- If you want to include the deleted records, select **Yes**.
- If you do not want to include the deleted records, select **No**.

c) Enter Default as the session name.

d) Save the outcome to a variable. For example, all the fields of the records can be stored in a list (List_SOQL)

3. Verify that you can run the bot in Debug mode with a breakpoint set to an action next to Execute SOQL. For example, in the sample provided previously, there is a Message box action. Open the List_SOQL variable to view the results.

The entire result set is returned as a response of the Salesforce Execute SOQL action and there is no limitation to the number of records returned.

Note: The response can have a high volume of data which might potentially degrade the performance of your automation.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation flow with the following steps:

- ServiceNow: Authentication Start a "Default" session on SPDL_urls
- ServiceNow: Get Multiple Records Get a list of "Incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

The 'View variable' dialog box displays the following information:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items

Additional details in the dialog:

- Use as input: No
- Use as output: No
- Constant (read-only): No
- Default value (optional): This list is empty

time.

Salesforce Upload file attachment action

You can upload a file to a record in Salesforce with the Salesforce Upload file attachment action.

Note: Ensure that you are authenticated before calling any Salesforce action. For more information about authentication, see [Salesforce Authentication action](#) on page 2846.

1. From the **Actions** pane, select **Salesforce > Upload file attachment** and place it in the canvas.
2. Enter the following fields:

The screenshot shows the configuration for the 'Salesforce: Upload file attachment' action. The configuration fields are as follows:

- Object's record ID:** 5004W000026rD4HQAU
- Content document record ID (optional):**
- File to be uploaded:** C:\Temp\InsertFilePath
- Display name (optional):**
- Visibility:** All users
- Session name:** Default
- Saves the outcome to a variable (optional):** DocVersionID

- a) Enter the **Object's record ID** to which you want to upload the file. For example: '5004W000026rD4HQUAU'.
- b) Enter a **Content document record ID (optional)**.
It is necessary only when you want to upload a newer version of an existing file.
- c) Select a location from where you want to upload the file. You will be able to select one of the following:
Control Room file: When you select this option, you can select a file from your Control Room.
Desktop file: When you select this option, you can select a file from your computer. In this sample, a file is uploaded from a folder in the computer.
Variable: When you select this option, you can select variable that points to a file.

Note: Make sure that the file path that you are referring to contains the file with the exact name as entered in this field.

- d) Enter the **Display name (Optional)** to save the uploaded file in this name.
 - e) Set the **Visibility** as required.
 - **AllUsers:** The file is available to all users who have permission to see the file.
 - **InternalUsers:** The file is available only to internal users who have permission to see the file.
 - **SharedUsers:** The file is available to all users who can see the feed to which the file is posted. **SharedUsers** is used only for files shared with users and is available only when an org has private org-wide sharing on by default. The **SharedUsers** value is available in API version 32.0 and later.
 - f) Enter Default as the session name.
 - g) Save the outcome to a variable. For example, the version of the saved document can be saved in a variable, such as DocVersionID.
3. To verify, you can run the bot and see whether the file is uploaded to the record in the Salesforce. The following video demonstrates uploading a file from a computer to Salesforce.

Salesforce Download file attachment action

You can download a file from a record in Salesforce by using the Salesforce Download file attachment action.

Note: Ensure that you are authenticated before calling any Salesforce action. For more information about authentication, see [Salesforce Authentication action](#) on page 2846.

1. From the **Actions** pane, select **Salesforce > Download file attachment** and place it in the canvas.
2. Enter the following fields:

The screenshot displays the Automation Anywhere configuration window for the 'Salesforce: Download file attachment' action. The interface is divided into several sections:

- Left Sidebar:** Contains 'Variables', 'Actions', and 'Triggers' sections. The 'Actions' section is expanded to show 'Salesforce' actions, with 'Download file attachment' highlighted.
- Main Workspace:** Shows a flowchart with three steps: 'Start', 'Salesforce: Authentication', and 'Salesforce: Download file attachment'. The 'Salesforce: Download file attachment' step is highlighted with a yellow box.
- Right Sidebar:** Shows the configuration for the 'Salesforce: Download file attachment' action. It includes fields for 'Object's record ID', 'Destination folder', 'Download all files/filter by', 'Session name', and 'Save the outcome to a variable (optional)'. Five callouts (a-e) point to these fields.

- a) Enter the **Object's record ID** from which you want to download the file. For example: '5004W000026rD4HQAU'
 - b) Enter the **Destination folder** where you want to save the file.
 - c) Set **Download all files/filter by** to one of the following options:
 - All files:** Download all the attached files from a record.
 - File name:** Download a file by entering a file name.
 - File extension:** Download all the files with the same extension that you enter.
 - Content document ID:** Download a particular version of a file.
 - d) Enter Default as the session name.
 - e) Save the outcome to a variable. For example, the details of the downloaded files can be saved in a variable, such as ListResponse
3. To verify, you can run the bot and whether the file is downloaded to the specified location. The following video demonstrates how to download a file from Salesforce to a location on a local system.

Note:

- The file is downloaded from the ContentDocument Object.
- File names are limited to 50 alphanumeric characters and any special characters are filtered when you download the file. The downloaded file name includes a document version ID that is appended before the file name, this ensures that the file name is unique. For example, if the file name is TEST_a_quick_brown_fox then the downloaded file name is 0684W00000c30XFQA2-TEST_a_quick_brown_fox.

Note: The output is retrieved as a list of type `List`. To read an individual record (row) in this list, you need to loop through all the dictionary items using the `Loop` action and read or extract the records (rows) individually. For example, the output of `get multiple records` is saved in the variable `list_of_records_any`. If the variable contains five records, then each record is passed to the `Loop` action to be processed one at a

The screenshot shows an automation workflow with the following steps:

- ServiceNow: Authentication Start a "Default" session on SPDI_urls
- ServiceNow: Get Multiple Records Get a list of "Incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

An orange arrow points from the "Get Multiple Records" step to a "View variable" dialog box. The dialog box shows the following details for the variable `list_of_records_any`:

Type	Subtype
List	Any
Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

The output contains information such as document title, content document ID, file path, file extension, download status and error message if any of the downloaded file.

SAP package

The SAP package contains actions to automate tasks and processes on a SAP application.

The SAP package enables you to perform the following tasks:

- Reduce the time required to combine data from disparate systems.
- Eliminate human error and increase efficiency.
- Increase the number of transactions processed.
- Deliver real-time information to various stakeholders.
- Enhance decision-making through comprehensive reports.

Note: In SAP **Connect** action, the **Session name** field cannot be shared with Task Bots or any other bots.

Prerequisites

- Log in to the SAP GUI before capturing objects because the SAP Logon screen is not supported for object capture.
- Enable GUI scripting and accessibility.
See [Enabling Scripting on the Client Side](#), [Enabling Scripting on the Server Side](#), and [Enabling Accessibility settings](#).
- Ensure that one of the following SAP GUI for Windows is installed on the devices that you use to automate SAP-related tasks and to run these tasks:
 - SAP GUI 750 with patch 9
 - SAP GUI 760 with patch 0

- SAP GUI 760 with patch 1
- SAP GUI 760 with patch 5
- SAP GUI 770 with patch 6

Note: If SAP GUI 760 with patch 0 is installed on your device, you cannot use the SAP Grid view control **Set Table cell text** and **Get Table Cell Text** actions because of an issue with SAP GUI 760 with patch 0.

- Install a Scripting Tracker or a similar tool to retrieve the field path of the SAP object.

Before you start

Perform the following actions within the SAP package as part of using the set of available actions:

1. Establish a connection with the SAP application using the **Connect** action.
Log in to the SAP application using the SAP GUI application. Then use the **Connect** action from the SAP package to use this connection and assign a session name. Use this same session name for the other actions.
2. Use the actions to automate a task.
3. After you have automated all the SAP-related tasks, terminate the connection to the SAP application using the **Disconnect** action.

Actions in the SAP package

The SAP package includes the following actions:

Note: The SAP and the Recorder package can detect SAP elements in the application. However, from a usability standpoint, the Recorder package is preferred over the SAP package as it is more intuitive when compared to the SAP package, such as detecting SAP Object paths automatically. See [Benefits of using Recorder package instead of SAP package](#) on page 2798

Action	Description
Check/uncheck checkbox	Check/uncheck check box action on page 2866
Click	Click action on page 2866
Click menu	Click menu action on page 2866

Related reference

[SAP package updates](#) on page 899

Review the updates in released versions of packages such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Check/uncheck check box action

The Check/uncheck check box action in the SAP package enables you to select or clear a check box in a SAP window.

Settings

- In the **Session name** field, enter the session name you used to connect to the SAP application in the **Connect** action.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Action** option, select **Check**, **Uncheck**, or **Toggle**.

Click action

The **Click** action enables you to include the click operation in the SAP application.

Settings

- Double-click or drag the **Click** action from the SAP package in the **Actions** palette.
- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.

For example, you can install a tool (such as Scripting Tracker or similar) to retrieve the field path of the SAP object.

- Click **Save**

Click menu action

The **Click menu** action enables you to click a menu item by text or index within a SAP window.

Settings

- Double-click or drag the **Click menu** action from the SAP package in the **Actions** palette.
- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.

For example, you can install a tool (such as Scripting Tracker or similar) to retrieve the field path of the SAP object.

- Use the **Select** field to select one of the following options:

- **Name:** to retrieve the value using the field name.

For example, you want to use the **Click menu** action on the new file menu in SAP window. In the **Name** field, enter **New**.

(Optional) Click the **Insert a value** icon to insert an existing variable for the **Name** field.

- **Index:** to retrieve the value using the index.

For example, there is a user log-in form that has a drop-down menu called **User type** with the following options:

- **New user**
- **Existing user**

You want to use the **Click menu** action on the **Existing user**. To select **Existing user** from the drop-down, ensure that you enter **2** in the **Index** field.

- Click **Save**.

Using Connect action for SAP

Use the **Connect** action to establish a connection with a SAP system that you want to use to automate SAP-related tasks. This must be the first action you use to automate an SAP-related task.

1. In the **Actions** palette, double-click or drag the **Connect** action from the **SAP** package.
2. Enter a name for the session in the **Session name** field.
3. Select one of the following options to specify the connection type:

- **Automatic**

No additional information is required to connect to the SAP application. You must be already logged in to SAP application as the system uses the available SAP session to connect to a SAP system.

- **SAP SSO**

In the **Name** field, enter the value that is displayed in the **Name** column of the SAP Logon screen.

Note: While creating a new entry, the value that you have entered in the **System Connection Parameters > Description** field is displayed under the **Name** field in the SAP Logon screen.

- **SAP GUI**

Enter the following details:

- **Name:** Enter the **Connection Name > Description Property Value** that is entered in the SAP Logon screen at the time of creating a new connection using **System Entry Properties**.

(Optional) Click the **Insert a value** icon or press 'F2' from the keyboard to select an existing variable.

- **Client:** Enter a client identifier value.

For example, you can specify any number from 0 through 999.

- **User name:** Click one of the following tabs:

- **Credential:** Enables you to use a value available in the Credential Vault. Click the **Pick** button to select a credential.
- **Variable:** Enables you to use a value that is stored as a credential variable.
- **Insecure string:** Enables you to specify the values.

- **Password:** Click one of the following tabs:
 - **Credential:** Enables you to use a value available in the Credential Vault. Click the **Pick** button to select a credential.
 - **Variable:** Enables you to use a value that is stored as a credential variable.
 - **Insecure string:** Enables you to specify the values.

- **Language:** Specify the two-letter code for the language set on the SAP server. For example, EN for English.

(Optional) Click the **Insert a value** icon or press 'F2' from the keyboard to select an existing variable.

4. Click **Save**.

Related tasks

[Using Export table action](#) on page 2869

Use the **Export table** action to export a table to a datatable or CSV file.

[Using Set table cell text action](#) on page 2875

Use the **Set table cell text** action to set the text in a specific cell of a table or a grid.

Related reference

[SAP package](#) on page 2863

The **SAP** package contains actions to automate tasks and processes on a SAP application.

Disconnect action

The Disconnect action in the SAP package enables you to terminate the connection to the SAP application.

Settings

In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .

Double click action

The **Double click** action enables you to perform a double-click operation in a SAP window.

Settings

- Double-click or drag the **Double click** action from the SAP package in the **Actions** palette.
- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .

- In the **Field path** field, specify the location or a string variable that contains the location of the object.

For example, you can install a tool (such as Scripting Tracker or similar) to retrieve the field path of the SAP object.

- Click **Save**

Expand action

The Expand action in the SAP package enables you to expand the item by text or index on a SAP window.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Select** option, select **Text** or **Index** to specify the text or index of the item.

Using Export table action

Use the **Export table** action to export a table to a datatable or CSV file.

To export a table, follow these steps:

1. In the Actions palette, double-click or drag the **Export table** action from the SAP package.
2. In the **Session name** field, enter the session name you used to connect to the SAP application in the **Connect** action.
3. In the **Field path** field, specify the location or a string variable that contains the location of the object.

You can use Recorder capture action to capture SAP controls and retrieve the field path or install a Scripting Tracker or a similar tool to retrieve the field path of the SAP object.

4. In the **Export As** option, select **CSV** or **Datatable** to specify the export option of the table cell:

Choice	Steps
CSV	<ol style="list-style-type: none"> a) In the File Path field, specify the location or file variable. b) Optional: In the Encoding field, specify the value. c) Select the Export data with header check box to export with header. d) In the When saving field, select Append to existing log file or Overwrite existing log file to append the log file or overwrite the content within the log file.
Datatable	In the Datatable field, specify the value.

5. Click **Save**.

Get cell count action

The Get cell count action in the SAP package enables you to get number of cells in a table or grid.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Assign the output to a variable** field, specify the variable.

Get children names action

The Get children names action in the SAP package enables you to get children control names.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Assign the output to list variable** field, specify the list variable.

Get children text action

The Get children text action in the SAP package enables you to get the text associated with children control.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Assign the output to list variable** field, specify the list variable.

Get column count action

The Get column count action in the SAP package enables you to get number of columns in a table or grid.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Assign the output to a variable** field, specify the variable.

Get row count action

The Get row count action in the SAP package enables you to get number of rows in a table or grid.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Assign the output to a variable** field, specify the variable.

Get selected item action

The Get selected item action in the SAP package enables you to get selected item index from a combo box, page tab, or a tree view control.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Assign the output to a variable** field, specify the variable.

Get status action

The Get status action in the SAP package enables you to get status of a radio button or check box.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Assign the output to a variable** field, specify the variable.

Get table cell index action

The Get table cell index action in the SAP package enables you to get table cell index for text.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Search text** field, specify the text.
- Select the **Case sensitive search** option to specify a case-sensitive search.
- Select the **All occurrences** check box.
- In the **Assign the output to a variable** field, specify the variable.

Get table cell text action

The **Get table cell text** action in the SAP package enables you to get table cell text by index.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.

For example, you can install a tool (such as Scripting Tracker or similar) to retrieve the field path of the SAP object.

- In the **Row** field, specify the row number from where you want to get the text.

For example, if you want to get text in tenth row, enter 10 in the **Row** field.

(Optional) Click the **Insert a value** icon to select an existing variable for the **Row** field.

- In the **Column** field, specify the column number from where you want to get the text.

For example, if you want to get text from the third column, enter 3 in the **Column** field.

- (Optional) Click the **Insert a value** icon to select an existing variable for the **Column** field.
- Click the **Assign the output to a variable** drop-down menu and select the variable to which you want to assign the output.
- (Optional) Click the **Create variable** icon if there is no existing variable.

Get text action

The Get text action in the SAP package enables you to get text from a text box, label, or status bar.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Assign the output to a variable** field, specify the variable.

Get item count action

The Get item count action in the SAP package enables you to get the count of items in a combo box, page tab, or tree view control.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Assign the output to a variable** field, specify the variable.

Left click action

The **Left click** action enables you to perform a left-click operation.

Settings

- Double-click or drag the **Left click** action from the SAP package in the **Actions** palette.
- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.

For example, you can install a tool (such as Scripting Tracker or similar) to retrieve the field path of the SAP object.

- Click **Save**

Right click action

The **Right click** action enables you to perform a right-click operation.

Settings

- Double-click or drag the **Click menu** action from the SAP package in the **Actions** palette.
- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.

For example, you can install a tool (such as Scripting Tracker or similar) to retrieve the field path of the SAP object.

- Click **Save**.

Select item action

The Select item action in the SAP package enables you to select an item by text or index.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.
- In the **Select** option, select **Text** or **Index** to specify the text or index of the item.

Select radio option action

The Select radio option action in the SAP package enables you to select the radio button in a SAP window.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Field path** field, specify the location or a string variable that contains the location of the object.

Send virtual key action

The Send virtual key action in the SAP package enables you to send a virtual key.

Settings

- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Select** list, select a key.

See [Virtual keys in SAP GUI](#).

Using Set table cell text action

Use the **Set table cell text** action to set the text in a specific cell of a table or a grid.

To set a value in a table cell, follow these steps:

1. In the **Actions** palette, double-click or drag the **Set table cell text** action from the SAP package.
2. In the **Session name** field, enter the session name you used to connect to the SAP application in the **Connect** action.
3. In the **Field path** field, specify the location or a string variable that contains the location of the object.
4. In the **Select** option, select **Text** or **Index** to specify the text or index of the table cell:
 - **Text**: In the **Find Text** field, specify the value.
The system searches for the cell that contains the value.
 - **Index**: In the **Row** and **Column** fields, specify the value.
5. In the **Set Text** field, enter the text to set the table cell.
6. Click **Save**.

Set text action

The **Set text** action in the SAP package enables you to set the text in an editable field (such as textbox).

Settings

- Double-click or drag the **Set text** action from the SAP package in the **Actions** palette.
- In the **Session name** field, enter the session name you used to connect to the application in the **Connect**.
- In the **Field path** field, specify the location or a string variable that contains the location of the object.

For example, you can install a tool (such as Scripting Tracker or similar) to retrieve the field path of the SAP object.

(Optional) If you have stored the location of the object as a variable, click the **Insert a variable** icon to select that variable.

- (Optional) In the **Field value** field, enter the text that you want to specify or set.

Alternately, click the **Insert a variable** icon to select an existing variable that contains the text you want to set.

Note: You can set the fields to any value, including blank values. For example, text field or date field.

- (Optional) Select the **Append text** check box if you want to add or append the text with any existing text in the editable field.

If you do not select the check box, the content in the editable field will be overwritten.

SAP BAPI package

The SAP BAPI package contains actions to automate tasks and processes using SAP Business Application Programming Interface (BAPI). BAPI is a standardized method that enables a third-party application to interact with an SAP system.

Overview of SAP BAPIs

[Business Application Programming Interfaces \(BAPIs\)](#) are APIs that enable external applications to access SAP business objects.

Typically, a BAPI consists of the following parameters:

- Import parameters: Used to receive data from the calling applications.
- Export parameters: Used to return data to the calling application.
- Import/export table parameters: Tables used for both receiving data and returning data.

A parameter can be of the following type:

- Data element: Scalar data type
- Structure: Typically contains multiple fields

If an import parameter is of the type structure, you can pass multiple values as key-value pairs.

- Table: A data structure that contains more than one row

For a BAPI method to work, the calling application can call the method in a BAPI using the following:

- BAPI name
- Import parameters (scalar, structure, table)
- Export parameters (scalar, structure, table)

Before you start

Perform the following actions within the SAP BAPI package as part of using the set of available actions:

1. Establish a connection with the SAP application using the **Connect** action.
2. Use the **Create function** action to create a user-defined function for the specified SAP BAPI function.
Select the **Begin sequence** option to mark the start of a process followed by the actions to automate a task.
3. Use the **Run function** action to run the function you have created using the **Create function** action.
Select the **End sequence** option to mark the end of a process and the **Commit transaction** option to commit the changes.

Actions in the SAP BAPI package

The SAP BAPI package includes the following actions:

Action	Description
Connect	Using Connect action for SAP BAPI on page 2878.
Create function	Create function action on page 2880.
Get field value	Get field value action on page 2880.
Get structure	Get structure action on page 2881.
Get table	Get table action on page 2881.
Run function	Run function action on page 2881.
Set field value	Set field value action on page 2882.
Run standard workflow	Run standard workflow action on page 2882.
Run custom workflow	Run custom workflow action on page 2883.

Build sample bots using the SAP BAPI package

If you are getting started with the SAP BAPI package, a good place to start is to build some sample bots with the help of the following tutorials. The tutorials are intended to train you on how to use various actions from the SAP BAPI package to invoke SAP BAPIs, pass import parameters, and retrieve data from export parameters.

- [Example of using Get structure command from SAP BAPI package](#) on page 3101: In this tutorial, you will build a bot that invokes BAPI_FLIGHT_GETLIST from the SAP demo Flight Data application. When executed, the bot calls the BAPI function by inputting an airline ID and destination details, gets a list of flights, and writes the response data to a CSV file.
- [Example of writing data to SAP using SAP BAPI package](#) on page 3103: In this tutorial, you will build a bot that invokes BAPI_FLICUST_CREATEFROMDATA from the SAP demo Flight Data application. You will use the CUSTOMER_DATA import parameter to pass the customer data to the BAPI. When executed, the bot creates a new customer record in SAP database and displays the customer number returned by the BAPI.

- [Example of using Run standard workflow from SAP BAPI package](#) on page 3105: In this tutorial, you will build a bot that uses a single action to select a BAPI from a list of function modules, to set import parameters, and to get the response data. When executed, the bot gets flight availability data based on the input data, and writes it to a CSV file.

Related reference

[SAP BAPI package updates](#) on page 898

Review the updates in released versions of SAP BAPI package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using Connect action for SAP BAPI

Use the **Connect** action to establish a connection with a SAP system that you want to use to automate SAP-related tasks using SAP Business Application Programming Interface (BAPI). This must be the first action you use to automate an SAP-related task using SAP BAPI.

Download the SAP Java connector package and DLL from the SAP website.

1. In the **Actions** palette, double-click or drag the **Connect** action from the **SAP** package.
2. In the **SAP BAPI Session** field, specify a name for the session.
3. In the **JCo: SAP Java Connector package** field, specify the location of the SAP Java connector package as credential, variable, or an insecure string.

Note: The credential, variable, and insecure string fields mentioned in this topic are defined as follows:

- **Credential:** Enables you to use a value available in the Credential Vault.
- **Variable:** Enables you to use a value that is stored as a credential variable.
- **Insecure string:** Enables you to manually specify the values.

-
4. In the **JCo DLL dependency** field, specify the location of the SAP JCo DLL dependency as a credential, variable, or an insecure string.
 5. In the **Connection type**, select one of the following options:
 - **Custom Application Server:**
Specify the SAP server hostname as a credential, variable, or an insecure string.
 - **Group/Server:**
 - a) Specify the SAP message server hostname as a credential, variable, or an insecure string.
 - b) Optional: Specify the gateway host you want to use to connect to the server in the **Gateway host** field.
 - c) Optional: Specify the logon group you want to use to connect to the server in the **Logon group** field.
 6. In the **System number** field, specify the two digit instance number.
 7. (Optional) In the **SAP instance system ID** field, specify the unique three character code of your SAP instance.
 8. In the **Client number** field, specify the three digit client number.

9. In the **Logon language code** field, specify the two-character language code based on ISO 639-1. For example: EN (for English).
10. (Optional) In the **Router string** field, specify the SAP router path when the target server is behind a firewall.
11. In the **Authentication type** field, select one of the following options:
 - **Username and password:**

Specify the username and password of your SAP BAPI account.
 - **SNC:**

Secure Network Communications (SNC) integrates SAP NetWeaver Single Sign-On (SSO) or an external security product with SAP systems. SNC secures the data communication paths between the various SAP system client and server components. Select this option to strengthen security by using additional security functions that are not directly available with SAP systems.

 - a) Specify the SNC name of the communication partner.
 - b) In the **Protection level** field, select the required data protection level to apply from the drop-down list.
 - When using **Authentication only** protection level, the system verifies the identity of the communication partners. This is the minimal protection level offered by SNC.
 - When using **Integrity Protection**, the system detects any changes or manipulation of the data which might have occurred between the two endpoints of a communication.
 - When using **Privacy Protection**, the system encrypts the messages being transferred. Privacy protection also includes integrity protection of the data.
 - **Default Protection** applies the global default protection level.
 - **Maximum security settings available** is the maximum value that the current security product supports.
 - c) In the **SNC library** field, specify the path and file name of the external security product library as a credential, variable, or an insecure string.
 - d) Select the **Login with username and password** check box and specify the username and password as a credential, variable, or an insecure string.

Note: For SSO authentication login, you do not have to provide the username and password. To authenticate without SSO, you must provide the username and password.

Create function action

The Create function action in the SAP BAPI package enables you to create an alias for a SAP BAPI function and saves it with an alias name.

Settings

You can use the alias name in other actions to use that BAPI function in those actions.

- In the **Session name** field, enter the session name you used to connect to the SAP application in the **Connect** action.
- In the **Function alias name** field, enter the alias that you want to use for the BAPI function.
- In the **BAPI name** field, enter name of the SAP BAPI function for which you want to create the alias.
- Select the **Begin sequence** option if you want to execute the BAPI in a particular sequence to mark the start of a process.

Get field value action

The Get field value action in the SAP BAPI package enables you to obtain data of a specific field from a function, table, or structure.

Settings

- In the **BAPI function alias** field, enter the alias you have provided for SAB BAPI function using the **Create function** action.
- Select one of the following option to specify whether you want to obtain data from a function, table, or structure:

- **Function**: Enables you to get the value of a field from a function.
- **Table**: Enables you to get the value of a field from a table in a SAP BAPI function.

You must specify the **Table alias** from which you want to obtain data.

You must use the **Get table** action before you use the **Get field** action to obtain the value of a field from a table in a SAP BAPI function. You must also specify the **Table alias** from which you want to get data.

- **Structure**: Enables you to obtain data from a structure in a SAP application.

You must use the **Get structure** action before you use the **Get field** action to obtain the value of a field from a structure in a SAP BAPI function. You must also specify the **Table alias** from which you want to obtain data.

- In the **Field name** field, enter the name of the field from which you want to get data.
- In the **SAP BAPI Session** field, enter the session name you used to connect to the SAP application in the **Connect** action.
- In the **Save the output to a variable** field, specify a string variable.

Get structure action

The Get structure action in the SAP BAPI package enables you to obtain table data from a structure using the function alias.

Settings

- In the **BAPI function alias** field, enter the alias you have provided for SAB BAPI function using the **Create function** .
- In the **Structure name** field, enter the name of the structure from which you want to get data.
- In the **SAP BAPI Session** field, enter the session name you used to connect to the application in the **Connect** .
- Select one of the following options to specify how you want to save the data retrieved from the structure:
 - **Alias**: Enables you to provide an alias for the structure and use the alias in other actions.
 - **Variable**: Enables you to store the data retrieved from the structure in a table variable.

Get table action

The Get table action in the SAP BAPI package enables you to get tabular data from a table using the function alias.

Settings

- In the **BAPI function alias** field, enter the alias you have provided for SAB BAPI function using the **Create function** .
- In the **Table name** field, enter the name of the table from which you want to obtain data.
- In the **SAP BAPI Session** field, enter the session name you used to connect to the application in the **Connect** .
- Select one of the following options to specify how you want to save the data retrieved from the table:
 - **Alias**: Enables you to provide an alias for the table and use the alias in other actions.
 - **Variable**: Enables you to store the data retrieved from the table in a table variable.

Run function action

The Run function action in the SAP BAPI package enables you to run the SAP BAPI function.

Settings

- In the **BAPI function alias** field, enter the alias you have provided for SAB BAPI function using the **Create function** .
- Select the **End sequence** option to mark the end of a process and the **Commit transaction** option to commit the changes made during the process.

If you want to end a sequence, you must select the **Begin sequence** option from the **Create function** action. If you have used queued Remote Function Call (qRFC), you must select the **Commit transaction** option to commit the changes you have made.

- In the **SAP BAPI Session** field, enter the session name you used to connect to the application in the **Connect** .

Set field value action

The Set field value action in the SAP BAPI package enables you to set data into a function, table, or structure using the function alias.

Settings

- In the **BAPI function alias** field, enter the alias you have provided for SAB BAPI function using the **Create function** .
- Select one of the following options to specify whether you want to set data in a function, table, or structure:

- **Function**: Enables you to set data in a function.
- **Table**: Enables you to set data in a table in a SAP application.

You must use the **Get table** action before you use the **Get field** action to obtain the value of a field from a table in a SAP BAPI function. You must specify the **Table alias** in which you want to set data. You can also select the **Create new row** option if you want to create a new row in the table and set value in that row.

- **Structure**: Enables you to set data in a structure in a SAP application.

You must use the **Get structure** action before you use the **Get field** action to obtain the value of a field from a structure in a SAP BAPI function. You must also specify the **Structure alias** from which you want to get data.

- In the **Field name** field, enter the name of the field in which you want to set data.
- In the **Field Value** field, enter the value that you want to set.
- In the **SAP BAPI Session** field, enter the session name you used to connect to the application in the **Connect** .

Run standard workflow action

The Run standard workflow action in the SAP BAPI package enables you to run a standard workflow in SAP BAPI.

Settings

- Use the **Select workflow** option to select the workflow from the **Standard BAPI Selector** dialog box.
- The **Import to BAPI** section displays the import parameters for the selected workflow. You can select the **Edit** option from the action menu (vertical ellipsis) to specify a value for the parameters.
 - Select the **Include** option if you want to use that import parameter.

- Select the **Table** tab to select a table variable containing the values you want to import to BAPI. Alternatively, select the **Strings** tab to specify the value manually.
- The **Export to BAPI** section displays the export parameters for the selected workflow. You can select the **Edit** option from the action menu (vertical ellipsis) to specify a value for the parameters.
 - Select the **Include** option if you want to use that export parameter.
- The **Tables** section displays the tables you can use as export or import parameters for your selected workflow. You can select the **Edit** option from the action menu (vertical ellipsis) to specify a value for the tables.
 - Select the **Include** option if you want to use that table as an export or import parameter.
 - Select either the **Import** tab to use a table as an import parameter or select the **Export** tab to use a table as an export parameter.
 - Select the **Table** tab to select a table variable containing the values you want to import to BAPI. Alternatively, select the **Strings** tab to specify the value manually.
- Select the **Begin sequence** option if you want to execute the BAPI in a particular sequence to mark the start of a process.
- Select the **End sequence** option to mark the end of a process.
- Select the **Commit transaction** option to commit the changes made during the process.
- In the **SAP BAPI Session** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Save exported structures and scalars** field, specify a dictionary variable.
- In the **Save exported tables** field, specify a dictionary variable.

Run custom workflow action

The Run custom workflow action in the SAP BAPI package enables you to run a custom workflow in SAP BAPI.

Settings

Note: Adding a custom workflow is currently not supported in Automation 360. You can use the Remote function call (RFC) to execute the custom BAPI.

- Select the custom workflow you want to run from the **Select Custom workflow** list.
- The **Import to BAPI** section displays the import parameters for the selected workflow. You can select the **Edit** option from the action menu (vertical ellipsis) to specify a value for the parameters.
 - Select the **Include** option if you want to use that import parameter.
 - Select the **Table** tab to select a table variable containing the values you want to import to BAPI. Alternatively, select the **Strings** tab to specify the value manually.
- The **Export to BAPI** section displays the export parameters for the selected workflow. You can select the **Edit** option from the action menu (vertical ellipsis) to specify a value for the parameters.
 - Select the **Include** option if you want to use that export parameter.

- The **Tables** section displays the tables you can use as export or import parameters for your selected workflow. You can select the **Edit** option from the action menu (vertical ellipsis) to specify a value for the tables.
 - Select the **Include** option if you want to use that table as an export or import parameter.
 - Select either the **Import** tab to use a table as an import parameter or select the **Export** tab to use a table as an export parameter.
 - Select the **Table** tab to select a table variable containing the values you want to import to BAPI. Alternatively, select the **Strings** tab to specify the value manually.
- Select the **Begin sequence** option if you want to execute the BAPI in a particular sequence to mark the start of a process.
- Select the **End sequence** option to mark the end of a process.
- Select the **Commit transaction** option to commit the changes made during the process.
- In the **SAP BAPI Session** field, enter the session name you used to connect to the application in the **Connect** .
- In the **Save exported structures and scalars** field, specify a dictionary variable.
- In the **Save exported tables** field, specify a dictionary variable.

Screen package

Use the `Screen` package to automate the process of capturing screenshots. Using the actions in this package, you can capture an area of an application window, the entire computer screen, or an active open window and save it in a specified location in an image format.

Actions in the Screen package

The `Screen` package includes the following actions:

Action	Description
Capture area	See Using Capture area action from Screen package on page 2885.
Capture desktop	See Capture desktop action in Screen on page 2887.
Capture window	See Using Capture window action from Screen package on page 2887.

Secure recording

When secure recording mode is enabled, bots do not display the target object images after capture. This ensures that sensitive data is not shown.

Note: Although the bots do not display the target images after capture, the images are still stored in the Control Room because they are required to run the bots.

When you record a task in secure recording mode, the **Preview** window temporarily shows an image of the captured area. This image is hidden after you navigate away from the Bot editor window or refresh it.

A user with admin privileges must enable this setting. See [Settings](#) on page 1728.

[Screen resolution dependent packages](#) on page 1739

The screen resolution between the Bot Runner and Bot Creator device should be consistent as when resolution-dependent packages are used to build bots, any screen resolution difference between the Bot Creator and Bot Runner device will impact the bots during runtime.

[Screen package updates](#) on page 900

Review the updates in released versions of the Screen package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using Capture area action from Screen package

Use the **Capture area** action in the Screen package to capture a screenshot of the application window area.

To capture a specified area of an application window, perform these steps:

1. In the **Actions** palette, double-click or drag the **Capture area** action from the Screen package.
2. Specify the window in which to capture an object.

Choose from the **Application**, **Browser**, or **Variable** tab.

Option	Description
Application	Select from a list of currently active windows. This option shows a list of all the application and browser windows that are open on the Bot Creator device.
Browser	Select from a list of supported browser tabs. Note: This option supports , Chromium-based , and browsers. For all other browsers, use the Application option.
Variable	Select an existing window variable to specify the title of the application window title.

3. Optional: Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value.

For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `(\w*) -Notepad` for all window title names starting with `(\w*) -Notepad`, or use **Pattern** value as `(\w)\s*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

Note: During runtime, verify that the Task Bot identifies the correct window. If it does not, do the following:

- a) Open the application or browser window.
 - b) Drag a **Window > Get active window title** action above the **Recorder > Capture** action.
 - c) Insert a string variable into the **Assign the window title to variable** field.
 - d) Drag a **Window > Set title** action below the **Window > Get active window title** action.
 - e) In the **Window** field, insert the window variable generated by the **Recorder > Capture** action.
 - f) In the **New window title** field, insert the string variable from the **Get active window title** action.
 - g) Click **Save**.
-

4. Optional: Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.

- If the window is maximized when you record the task, this option is not selected.
 - If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.
-

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

5. Click the **Capture region**.

The pixel coordinates of the captured area are displayed in the **X, Y, Width, and Height** fields. You can modify these values.

6. Browse to select the **File path to save image**.
The following file extensions are supported: png, bmp, jpeg, tiff, gif, and wmf.
7. Click **Overwrite file** to replace an existing file with the same name.
8. Click **Save**.

Capture desktop action in Screen

The **Capture desktop** action in the Screen package enables you to capture an image of the entire desktop.

Settings

- In the **File path to save image** field, specify the path where you want to save the captured image.
The following file extensions are supported: png, bmp, jpeg, jpg, tiff, gif, and wmf.
- Select **Overwrite File** check box to overwrite an existing file with the same name.

Using Capture window action from Screen package

Use the **Capture window** action of the Screen package to capture an open application window.

To capture an application window, perform these steps:

1. In the **Actions** palette, double-click or drag the **Capture window** action from the Screen package.
2. Specify the window in which to capture an object.

Choose from the **Application**, **Browser**, or **Variable** tab.

Option	Description
Application	Select from a list of currently active windows. This option shows a list of all the application and browser windows that are open on the Bot Creator device.
Browser	Select from a list of supported browser tabs. Note: This option supports , Chromium-based , and browsers. For all other browsers, use the Application option.
Variable	Select an existing window variable to specify the title of the application window title.

3. Optional: Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value.

For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `(\w*)-Notepad` for all window title names starting with `(\w*)-Notepad`, or use **Pattern** value as `(\w)\s*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

Note: During runtime, verify that the Task Bot identifies the correct window. If it does not, do the following:

- a) Open the application or browser window.
 - b) Drag a **Window > Get active window title** action above the **Recorder > Capture** action.
 - c) Insert a string variable into the **Assign the window title to variable** field.
 - d) Drag a **Window > Set title** action below the **Window > Get active window title** action.
 - e) In the **Window** field, insert the window variable generated by the **Recorder > Capture** action.
 - f) In the **New window title** field, insert the string variable from the **Get active window title** action.
 - g) Click **Save**.
-

4. Optional: Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.

- If the window is maximized when you record the task, this option is not selected.
- If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

5. Browse to select the **File path to save image**.
The following file extensions are supported: png, bmp, jpeg, tiff, gif, and wmf.
6. Click **Overwrite file** to replace an existing file with the same name.
7. Click **Save**.

Service package

Use the Service package to automate operations in Windows and application services including starting, stopping, pausing, resuming, or getting the status of services.

Note: You must have administrator privileges to start, stop, pause, or resume service operations.

Actions in the Services package

The Services package includes the following actions:

Action	Description
Get service status	See Get service status action in Services on page 2890
Pause service	See Pause service action in Services on page 2890
Resume service	See Resume service action in Services on page 2890
Start service	See Start service action in Services on page 2890
Stop service	See Stop service action in Services on page 2891 .

Related reference

[Service package updates](#) on page 901

Review the updates in released versions of packages such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Pause service action in Services

The **Pause service** action in the Services package enables you to pause a Windows or application service that is currently running.

Settings

Select the **Service list** or **Variable** option to enter the name of the service that you want to pause.

Resume service action in Services

The **Resume service** action in the Services enables you to resume a selected Windows or application service that was previously paused.

Settings

Select the **Service list** or **Variable** option to enter the name of the service that you want to resume the services for.

Start service action in Services

The **Start service** action in the Services package enables you to start a selected Windows or application service that is not running.

Settings

Select the **Service list** or **Variable** option to enter the name of the service that you want to start the service for.

Get service status action in Services

The **Get service status** action in the Services enables you to retrieve the current status of a Windows or application service.

Settings

- Select either the **Service list** or the **Variable** option and to enter the name of the service that you want to get the status for.
- Select an appropriate variable that you can assign the status value to from the **Assign the output to an existing variable** option.

Example: The Windows Audio service status might be running.

Stop service action in Services

The **Stop service** action in the Services package enables you to stop a selected Windows or application service that is currently running.

Settings

Select the **Service list** or **Variable** option to enter the name of the service that you want to stop the service for.

ServiceNow package

ServiceNow is a leading software provider of digital work flows for enterprise operations. The Automation 360 ServiceNow command package uses the ServiceNow APIs to let you build and deploy bots in Automation 360 that work with records and triggers in ServiceNow.

This package provides actions to authenticate with ServiceNow and perform several actions with records and attachments. To perform these actions in ServiceNow, Automation 360 uses these APIs:

- [Table API](#)
- [Attachment API](#)

Automation 360 bots can increase process efficiency for these types of work flows: customer account creation and management, customer verification, employee on-boarding and off-boarding, data extraction and migration, and claims and invoice processing. Automation 360 helps extend the core work flow capabilities of ServiceNow so that you can automate repetitive tasks for intelligent, end-to-end automation. This Automation 360 command package enables Automation 360 bots and processes to use ServiceNow API features natively within the Automation 360 platform.

ServiceNow Triggers

You can use the ServiceNow triggers to start Automation 360 bots to respond to the events in ServiceNow such as incident creation, updates, and so on. For more information on ServiceNow triggers, see [ServiceNow New Record trigger](#) on page 3244 and [ServiceNow Updated Record trigger](#) on page 3245.

The following video shows the interaction between Automation 360 and ServiceNow when you use ServiceNow command package:

Use cases

The key use cases for this package include:

- Create, read, update, and delete records from a ServiceNow table.
- Add, download, and delete attachments on ServiceNow records.
- Streamline Incident responses.
- Trigger specific automations from the creation of new Incidents or Incident updates.

Prerequisites

- The bot creator must have access to a ServiceNow account with required permissions to perform tasks enabled by this package. See [Roles](#).
- Follow ServiceNow guidelines for authenticating to external client with OAuth 2.0. See [Setup OAuth](#).
- Create a Developer account and Developer instance in ServiceNow. See [Personal Developer Instances](#).

[ServiceNow package updates](#) on page 902

Review the updates in released versions of ServiceNow packages such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Authentication

Use the **Authentication** and **Revoke Authentication** action to connect or disconnect from your ServiceNow instance.

ServiceNow authentication action

Use the **Authentication** action to connect to your ServiceNow instance. After the authentication is successful, you can use other command actions to perform various operations in ServiceNow.

- You must have the Client ID and Client secret generated in your ServiceNow instance. To generate the Client details, see [Create an OAuth API endpoint for external clients](#).
- You must have the **Bot creator role** for your Automation Anywhere Control Room to use the ServiceNow package in a bot.

You can use different connection methods to connect to ServiceNow:

- **OAuth2 - Client Credentials:** Use this connection method by providing the Salesforce account credentials. You need a Salesforce username and password to establish a connection.
- **Control room OAuth connection:** Use this connection method by creating an OAuth connection and storing it in the Control Room. You must configure an OAuth connection in ServiceNow before creating the OAuth connection in Control Room. For more details, see [Create an endpoint for clients to access the instance](#).

1. Log in to the Control Room.
2. Create a new bot or edit an existing bot. See [Create your first bot](#) on page 1429.
3. From the Actions pane, select **ServiceNow > Authentication** and place it under the start of the bot flow.
4. In the **Authentication Type** field, select the authentication method from the drop down.
5. To view client ID and client secret details in ServiceNow for **OAuth2 - Client Credentials** authentication, complete the following steps:
 - a) Log in to your ServiceNow instance.
 - b) Click **All > Application Registry**.
 - c) Select the OAuth you created.

- d) Use the Client ID and Client Secret in your Authentication action from the Control Room.
6. To connect using OAuth2 - Client Credentials, complete the following steps:
- a) In the **ServiceNow URL** field, enter your ServiceNow instance URL.
 - b) (Optional) Enter the API version.
 - c) In the **Client ID** field, enter the Client ID copied from ServiceNow. In the example video below an Insecure string is used, while you can use Credential or Variable options for better security.
 - d) In the **Client Secret** field, enter the Client Secret copied from ServiceNow.
 - e) Enter the ServiceNow user name.
 - f) Enter the ServiceNow password.

Note: You can use one of the following options to specify the **Client ID/Client secret/username/ password**:

- **Credential:** Enables you to use a value in the Credential Vault that contains information about the Client ID/Client secret/username/password.
 - **Variable:** Enables you to use a credential variable that contains information about the Client ID/Client secret/username/passwordRI..
 - **Insecure string:** Enables you to enter the Client ID/Client secret/username/password manually.
-

7. To configure a **Control room OAuth connection** in ServiceNow, complete the following steps:
- a) Complete step 1 to step 5 in [Create OAuth connection](#) on page 1827.
 - b) Log in to your ServiceNow instance.
 - c) Click **New > Create an OAuth API endpoint for external clients**.
 - d) Enter the following details:
 - 1. **Name:** A unique name.
 - 2. **Client ID:** Client ID is automatically generated by the ServiceNow OAuth server.
 - 3. **Client Secret:** Client secret is automatically generated.
 - 4. **Refresh Token Lifespan:** Validity of refresh token in seconds.
 - 5. **Access Token Lifespan:** Validity of access token in seconds.
 - 6. **Redirect URL:** Add the Callback URL from [Create OAuth connection](#) on page 1827 as an authorized redirect URI.
 - 7. **Enforce Token Restriction:** Restricts the access token usage to the API 's defined in the REST API Access Policies. If this option is not selected, access token usage across other REST API's is allowed.
 - e) Click **Submit**.
 - f) Go to **Application Registry**. Click the info icon and copy the client ID and client secret.

- g) Go to [Create OAuth connection](#) on page 1827 and complete the remaining steps to create an OAuth connection with the above details.
8. To connect using **Control room OAuth connection**, pick a custom connection you have created and stored in the Control Room. For more details, see [Integrate OAuth with Control Room](#) on page 1824.
9. Enter **Default** as the Session name.
10. You can assign the authorization header to a variable by creating either a Multiple or Dictionary variable.
11. Click **Run** to save and run your bot. Once authenticated, you can use the token to call other ServiceNow API services.

ServiceNow revoke authentication action

Use the **Revoke Authentication** action to securely discard the refresh token and access token when you do not need them anymore.

1. From the **Actions** pane, select **ServiceNow > Authentication > Revoke Authentication** and place it under the bot flow.
2. Enter the session name and click Run.
3. After the bot runs, your ServiceNow access token is revoked.

Records

Use the **Records** action to perform various operations in your ServiceNow instance. You can create, update, delete, or get records from a ServiceNow Table.

ServiceNow create record action

Use the **Create Record** action to create a new data record in the ServiceNow Table app.

- Ensure that you are authenticated before calling any ServiceNow action. For more details, see [ServiceNow authentication action](#) on page 2892.
- You must create a table in your ServiceNow instance as this action only creates a new record for an existing table entry with the data provided. For more details, see [Creating a table](#).

1. From the Actions pane, select **ServiceNow > Records > Create Record** and place it in the canvas.
2. Specify details in the following fields:
 - a) Enter the Table name. You can use a standard table name available in ServiceNow, for example: Incident. Or you can use a custom user defined table name, for example: u_test_table.

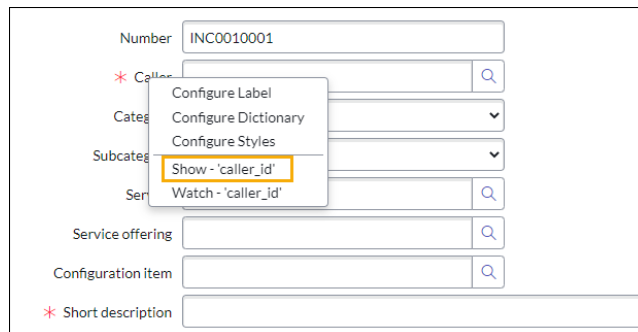

Note: For ServiceNow tables, ensure that you provide the Table name instead of the Label name.

 - b) Enter the Fields and data to insert. Choose either Dictionary or Entry list. For this example, Dictionary is selected.
 1. Select the Type as String, Number, Datetime, or Boolean based on the data you want to insert in the table.

2. Enter a key-value pair, where key is the ServiceNow field name and value is the data you want to update in the field.

Note: The key name for a field is different from the displayed label name. You can view the key name of the field by using one of the following options:

- In your ServiceNow developer instance, navigate to **System Definition > Language File**. You can use the filter option to view fields for specific Tables. For example: Incident.
- Right-click on the field name (as shown below) to display the key name. For example: caller_id is the key name for the field **Caller**.

The screenshot shows a configuration form with several fields. The 'Caller' field is highlighted with a red asterisk. A context menu is open over the 'Caller' field, listing options: 'Configure Label', 'Configure Dictionary', 'Configure Styles', 'Show - 'caller_id'', and 'Watch - 'caller_id''. The 'Show - 'caller_id'' option is highlighted with a yellow box. Other fields include 'Number' (INC0010001), 'Category', 'Subcategory', 'Service offering', 'Configuration item', and 'Short description' (marked with a red asterisk).

- c) Enter Default as the session name.
- d) Save the record ID to a variable. For example, the record ID is saved to sys_id.

ServiceNow: Create Record

Inserts one record in the specified table
Required bot agent version: 21.119 or above

Table name

a) (x)

Fields and data (optional)

Dictionary

b)

Type	Key	Value
String	caller_id	Jane-1234

+
Field names and values must be provided for required fields in the specified Table

Session name

c) (x)

Assign record id to a string variable (optional)

d) (x)

3. Click **Run** to save and run your bot.
4. Verify whether the record is created in the ServiceNow table.
 - a) Find the sys_id variable value in the Debug mode.
 - b) Replace the ID in the ServiceNow URL (as shown below) to view the latest record created.

https://dev85435.service-now.com/now/nav/ui/classic/params/target/incident.do%3Fsys_id%3D10256e5307669110efb1f1e08c1ed011%26s...

ServiceNow delete record action

Use the **Delete Record** action to delete a record from a ServiceNow table.

Ensure that you are authenticated before initiating any ServiceNow action. For more details, see [ServiceNow authentication action](#) on page 2892.

1. From the **Actions** pane, select **ServiceNow > Records > Get Record** and place it in the canvas.
2. Specify details in the following fields:
 - a) **Table name**: Enter the ServiceNow table name.
 - b) **Record Sys_id**: Enter the sys_id of the record. If the record ID is captured in a variable, you can provide the variable name.
 - c) The session name displays as **Default**.

ServiceNow: Delete Record

Deletes a record from the specified table

Required bot agent version: 21.119 or above

Table name

a) (x)

Record sys_id

b) (x)

Session name

c) (x)

3. Click **Run** to save and run your bot. When the bot is run successfully, your record in the ServiceNow table is deleted.

ServiceNow get record action

Use the **Get Record** action to retrieve a record using the record ID stored in sys_Id variable from ServiceNow.

Ensure that you are authenticated before initiating any ServiceNow action. For more details, see [ServiceNow authentication action](#) on page 2892.

1. From the **Actions** pane, select **ServiceNow > Records > Get Record** and place it in the canvas.
2. Specify details in the following fields:
 - a) **Table name**: Enter the ServiceNow table name.
 - b) **Record sys_id**: Enter the sys_id of the record. If the record ID is captured in a variable you can provide the variable name.
 - c) Select **List** for the **Field names (Optional)** field. Enter all the fields that you want to read.

- d) The session name displays as **Default**.
- e) Save the outcome to a variable. For example, the object ID is saved to dict_GetRecordResults.

ServiceNow: Get Record

e) (x)

3. Click **Run** to save and run your bot. When the bot is run successfully, the retrieved record is stored in the specified variable.

ServiceNow get multiple records action

Use the **Get Multiple Records** action to retrieve multiple records from a ServiceNow table.

Ensure that you are authenticated before initiating any ServiceNow action. For more details, see [ServiceNow authentication action](#) on page 2892.

1. From the **Actions** pane, select **ServiceNow > Records > Get Multiple Records** and place it in the canvas.
2. Specify details in the following fields:
 - a) **Table name:** Enter the ServiceNow table name.
 - b) Select **List** in the **List of fields to return in the response (Optional)** field. Enter the **Type** and **Value** for the fields you want to view in the response.
 - c) You can optionally filter the records by using name-value pair or query. For example, select **Query** and specify a query parameter to retrieve records for only the queried fields. For example, you can map the sys_id to a variable and add it as a query.
 - d) Specify a limit of records to view. If the **Limit** field is blank or set to 0, all records are returned. Response time might vary depending on the volume of the specified Table.

- e) The session name displays as **Default**.
- f) Save the outcome to a variable. For example, the object ID is saved to list_GetMultipleRecordsResult.

Filter records by

Name-value pair Query None

c Query (optional) (x)

d Limit (optional) (x)

If limit is left blank or set to 0, all records will be returned. Response time may vary depending on the volume of the specified Table

e Session name (x)

f Assign matched records to a list variable (x)

3. Click **Run** to save and run your bot. When the bot is run successfully, you will retrieve all the records from ServiceNow.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

The screenshot shows an automation canvas with the following steps:

- ServiceNow: Authentication Start a "Default" session on SPDI_urls
- ServiceNow: Get Multiple Records Get a list of "Incident" records using filter type (N
- Loop : For each item in the list
- Dictionary: Get value of the key "number" from \$ListItem\$
- Dictionary: Get value of the key "severity" from \$ListItem\$
- Dictionary: Get value of the key "short_description" from \$ListItem\$
- Message box "Record: \$O_inc_number\$, \$O_severity\$, \$O_descri
- ServiceNow: Revoke Authentication End the "Default" session

The 'View variable' dialog shows:

Type	Subtype

Name	Description
list_of_records_any	An ordered group of items
Use as input	No
Use as output	No
Constant (read-only)	No
Default value (optional)	This list is empty

time.

ServiceNow update record action

Use the **Update Record** action to update a record in ServiceNow with name-value pairs.

Ensure that you are authenticated before initiating any ServiceNow action. For more details, see [ServiceNow authentication action](#) on page 2892.

- From the **Actions** pane, select **ServiceNow > Records > Get Record** and place it in the canvas.
- Specify details in the following fields:
 - Table name:** Enter the ServiceNow table name.
 - Sys_id:** Enter the sys_id of the record. If the record ID is captured in a variable, you can provide the variable name.
 - In **Fields and data**, select **Dictionary** or **Entry list**. In the example, **Dictionary** is selected and the name-value pair is specified to update the record.
 - The session name displays as **Default**.

ServiceNow: Update a Record

Updates the specified record with the name-value pairs included in the request body

Required bot agent version: 21.119 or above

Table name
a

Sys_id
b

Fields and data
Dictionary Entry list
c Dictionary Variable

Type	Key
String	category
Value Hardware	

Session name
d

3. Click **Run** to save and run your bot. When the bot is run successfully, your record is updated with the specified details.

Attachments

Use the Attachments action to upload or delete an attachment from a record in the ServiceNow table. You can also download an attachment from a ServiceNow record.

ServiceNow add attachment action

Use the **Add Attachment** action to add a new attachment to the specified record in a ServiceNow Table app.

Ensure that you are authenticated before initiating any ServiceNow action. For more details, see [ServiceNow authentication action](#) on page 2892.

1. From the Actions pane, select **ServiceNow > Attachments > Add Attachment** and place it in the canvas.
2. Specify details in the following fields:
 - a) Enter the Table name.

Note: For ServiceNow tables, ensure that you provide the Table name instead of the Label name.

- b) Select the File to be uploaded by using one of the following options:

- **Control Room file:** If the file exists within the Control Room folders, select this option.
- **Desktop file:** If the file exists in your local system desktop, select this option and browse the file path.
- **Variable:** You can also store the file path as a variable.

Note: Maximum size of the file to upload cannot exceed 25 MB.

- (Optional) You can enter a name in the New file name field.
- The session name displays as **Default**.
- You can assign the attachment ID to a string variable. For example, the attachment ID is saved to str_AttachmentSysId.

ServiceNow: Add Attachment

Adds an attachment to the specified record
Required bot agent version: 21.119 or above

Table name
a (x)

Sys_id
b (x)

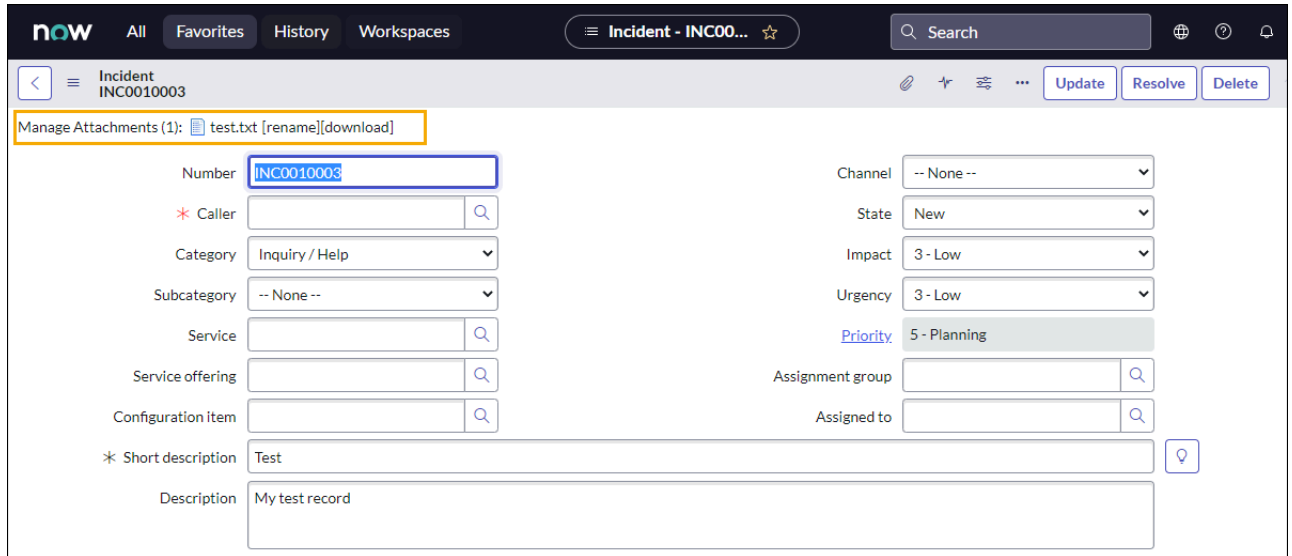

File to be uploaded
Control Room file Desktop file Variable
c (x) Browse...

New file name (optional)
d (x)

Session name
e (x)

Assign attachment sys_id to a string variable (optional)
f (x)

3. Click **Run** to save and run your bot.
4. Verify whether the attachment is added in the ServiceNow record as shown below:

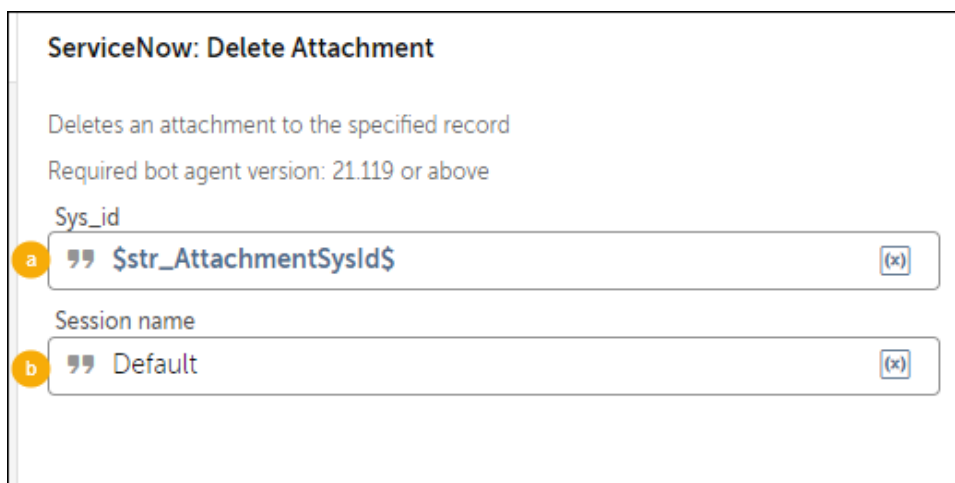

ServiceNow delete attachment action

Use the **Delete Attachment** action to delete an attachment from a ServiceNow record.

Ensure that you are authenticated before initiating any ServiceNow action. For more details, see [ServiceNow authentication action](#) on page 2892.

1. From the **Actions** pane, select **ServiceNow > Attachments > Delete Attachment** and place it in the canvas.
2. Specify details in the following fields:
 - a) **Sys_id**: Enter the attachment ID or select the variable where you stored the attachment ID.
 - b) The session name displays as **Default**.

3. Click **Run** to save and run your bot. When the bot is run successfully, your attachment in the ServiceNow record is deleted.

ServiceNow get attachment action

Use the Get Attachment action to download a new attachment from the specified record in a ServiceNow Table app.

Ensure that you are authenticated before initiating any ServiceNow action. For more details, see [ServiceNow authentication action](#) on page 2892.

1. From the Actions pane, select **ServiceNow > Attachments > Get Attachment** and place it in the canvas.
2. Specify details in the following fields:
 - a) **Filter attachment by.**
 - **Sys_id:** Specify the attachment ID or select a variable where the attachment ID is stored.
 - **Associated record:** Specify details of the associated record, to download the associated attachment. You must enter the table name and the table ID.
 - **Query:** Specify a query parameter to download the attachments. For example, you can map the sys_id to a variable and add it as a query.
 - b) Enter a Destination folder path, or select a variable if the path is stored in a variable.
 - c) The session name displays as **Default**.
 - d) You can assign the attachment ID to a string variable. For example, the attachment ID is saved to list_GetAttachmentResults.

ServiceNow: Get Attachment

Downloads attachment(s) to the specified folder location

Required bot agent version: 21.119 or above

Filter attachment by

a) Sys_id Associated record Query

Sys_id

b) \$str_AttachmentSysId\$ (x)

Destination folder path

b) \$str_DestinationFolderPath\$ (x)

e.g C:\Users\...\attachment-download-folder

Session name

c) Default (x)

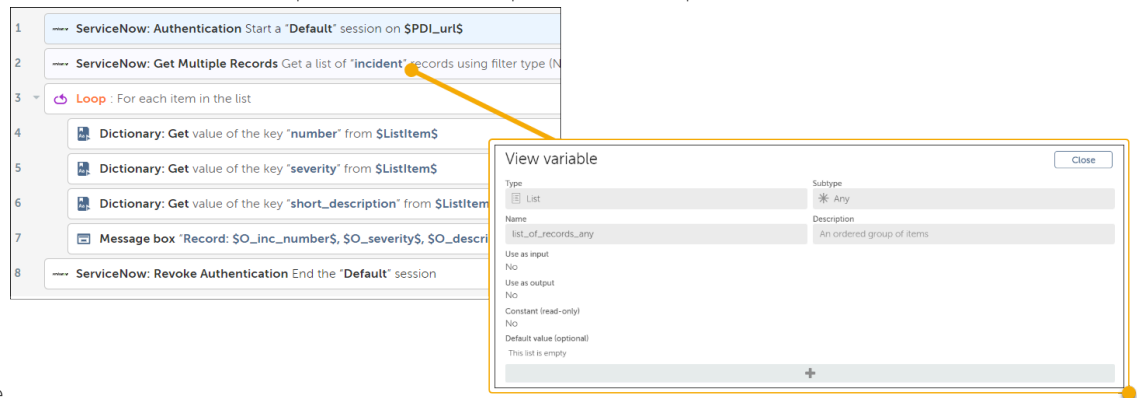

Assign file metadata to a list variable (optional)

d) list_GetAttachmentResults (x)

3. Click **Run** to save and run your bot.
4. The attachment is downloaded to the specified folder path.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

time.

ServiceNow field types: Table API

The ServiceNow schema contains various fields that you can modify by using the Automation 360 ServiceNow command package. The following table lists alphabetically the supported field types and their corresponding Automation 360 to ServiceNow actions.

SharePoint package

SharePoint is a web-based platform that is used for collaboration and document management. You can use the Automation 360 SharePoint command package to manage your documents, sites, and data.

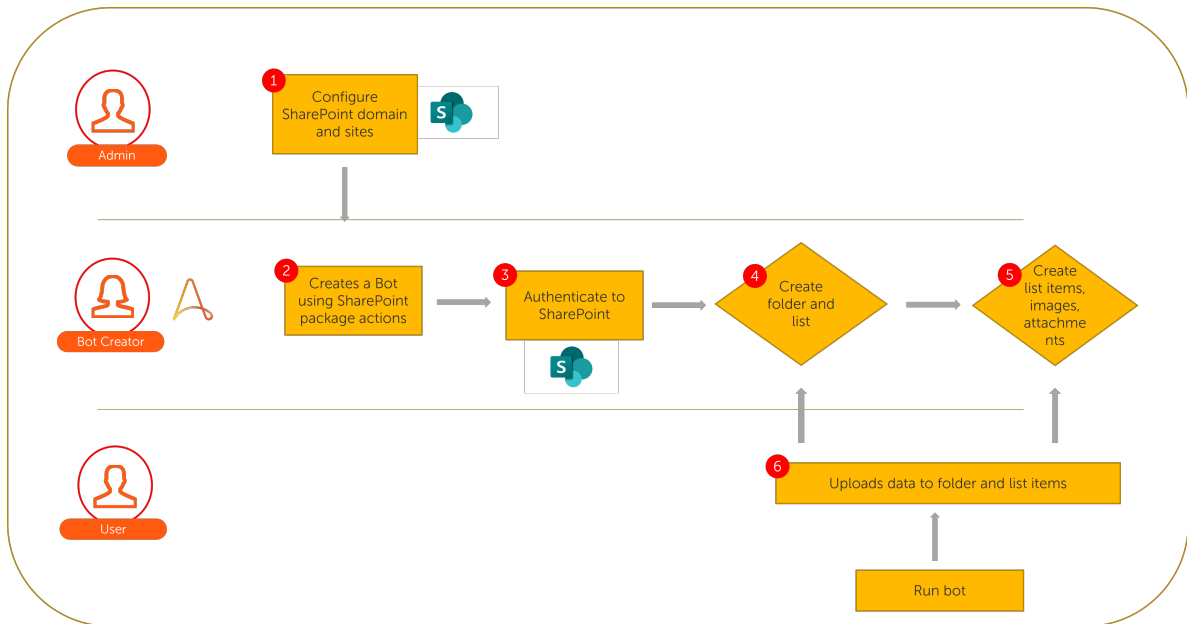

SharePoint is a collaborative platform that integrates natively with Microsoft Office. You can use the SharePoint package to securely store, organize, share, and access information. You can streamline processes and reduce manual work using the automated SharePoint operations in Automation 360. You can quickly and easily manage your documents, sites, and data. Automation 360 platform provides automation capabilities for other Microsoft products such as Microsoft Office, Outlook, and Windows. By adding the SharePoint package, you can leverage the full potential of the Microsoft platform from Automation 360.

Note: This package is new in v.29 and is based on the SharePoint REST v1 API.

You can use the SharePoint package to perform the following CRUD (create, read, update, and delete) actions in a SharePoint site:

- [CRUD operations for folder and file](#)
- [CRUD operations for list and list items](#)

SharePoint workflow

Actions in SharePoint package

You can perform the following actions in the SharePoint package:

Action	Description
Configuring SharePoint domain and sites	The SharePoint package connects to a particular SharePoint domain using app-based permissions. You must configure your SharePoint domain and add relevant app permissions.
SharePoint authenticate action	Use the Authenticate action to connect to your SharePoint domain. After the authentication is successful, you can use the other command actions to perform various operations in SharePoint.
SharePoint folder and file	Use the Folder and file actions to perform various operations in your SharePoint site. You can create, get details, delete, or rename folders in a specific SharePoint site. You can also upload, delete, download, and get files in a specified folder.
SharePoint list and list items	Use the List and list item actions to perform various operations in your SharePoint site. You can create, get, delete, or update list and list items in a specific SharePoint site.

[SharePoint package updates](#) on page 903

Review the updates in released versions of SharePoint packagesuch as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Configuring SharePoint app, sites, and app permissions

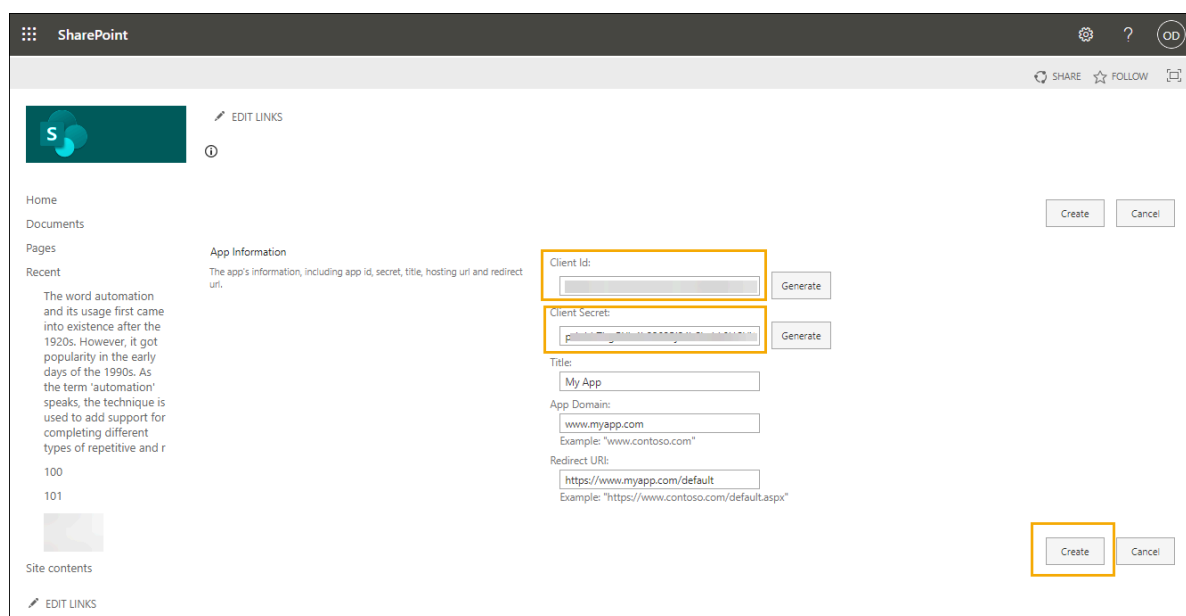

The SharePoint package connects to a particular SharePoint domain using app-based permissions. You must configure your SharePoint domain and add relevant app permissions.

To register and configure a new app in SharePoint, you must complete the following steps before using the SharePoint package. You can use the client ID and client secret of the newly registered app to log in to SharePoint through the Automation 360 SharePoint package.

Configure new app

1. To register a new app, go to: https://{your_sharepoint_domain}/_layouts/15/appregnew.aspx. Replace {your_sharepoint_domain} with your specific SharePoint domain (for example: automationanywhere.sharepoint.com).
2. Click Generate to generate a new client ID and client secret.
3. You can view the app details in the confirmation page. Copy and save the details to use in the package.

Note: You must have the SharePoint Administrator role to access the registration link.

The screenshot displays the SharePoint 'App Information' registration page. The page is titled 'App Information' and includes a sub-header: 'The app's information, including app id, secret, title, hosting uri and redirect uri.' The form contains the following fields and buttons:

- Client Id:** A text input field with a 'Generate' button to its right. This field is highlighted with an orange box.
- Client Secret:** A text input field with a 'Generate' button to its right. This field is highlighted with an orange box.
- Title:** A text input field containing 'My App'.
- App Domain:** A text input field containing 'www.myapp.com'. Below it, an example is shown: 'Example: "www.contoso.com"'. This field is highlighted with an orange box.
- Redirect URL:** A text input field containing 'https://www.myapp.com/default'. Below it, an example is shown: 'Example: "https://www.contoso.com/default.aspx"'. This field is highlighted with an orange box.
- Create and Cancel buttons:** There are two 'Create' buttons and two 'Cancel' buttons. One 'Create' button is highlighted with an orange box.

Configure app permissions

Once you have registered the app, you must configure the app-based permission.

1. To configure app permission, go to: `https://{your_sharepoint_domain}/_layouts/15/appinv.aspx`. Replace `{your_sharepoint_domain}` with your specific SharePoint domain (for example: `automationanywhere.sharepoint.com`).
2. Enter the client ID for the newly created app and click **Lookup**. Your app details will be displayed. Copy the following XML snippet and paste it in the **Permission Request XML** box:

```
<AppPermissionRequests AllowAppOnlyPolicy="true">
  <AppPermissionRequest Scope="http://sharepoint/content/
sitecollection" Right="FullControl" /> </AppPermissionRequests>
```

3. Click **Create** to save your changes.

The screenshot shows the SharePoint 'App Inv' configuration page. The 'App Id' field has a 'Lookup' button. The 'Title' field is filled with 'My App'. The 'App Domain' field is filled with 'www.myapp.com'. The 'Redirect URL' field is filled with 'https://www.myapp.com/default'. Below these fields is a 'Permission Request XML' field containing the XML snippet: `<AppPermissionRequests AllowAppOnlyPolicy="true"> <AppPermissionRequest Scope="http://sharepoint/content/sitecollection" Right="FullControl" /> </AppPermissionRequests>`. The 'Create' button is highlighted with a yellow box.

4. In the next screen, click **Trust It** to grant the required permissions.

Configure individual SharePoint sites

You must configure individual SharePoint sites. If you have multiple SharePoint sites in your organization, repeat this process for each individual site you want to connect to.

1. To configure individual sites, go to: `https://{your_sharepoint_domain}/sites/{sitename}/_layouts/15/appinv.aspx`. Replace `{your_sharepoint_domain}` with your specific SharePoint domain (for example: `automationanywhere.sharepoint.com`) and `{sitename}` with the site name you have created.
2. Follow the instructions provided in [Configure app permissions](#) on page 2910, to add the app based permissions to your SharePoint site.

Important: You need the **Full Control** permission to access the configuration link. It is recommended that you contact the owner of the SharePoint site, your SharePoint admin, or Microsoft 365 admin to get the **Full Control** permission. If you have Edit, Contribute, or Design permissions to the SharePoint site, you cannot access the configuration link.

Configure OAuth connection in SharePoint

You must configure an OAuth connection in SharePoint before creating the OAuth connection in Control Room.

1. Complete step 1 to step 5 in [Create OAuth connection](#) on page 1827.
2. Log into [Azure portal](#) and navigate to **App Registration**.
3. Click **New registration** and enter the following details:
 - a) Enter a name for the app.
 - b) Select **Single Tenant**.
 - c) In the **Redirect URI** field, select **Web** from the drop-down and enter the callback URL from [Create OAuth connection](#) on page 1827.

Note: For the OAuth connection to be successful you must enter the callback URL.

- d) Click **Register**.
4. Go to **App Overview**.
5. Copy the client ID from the Application (client) ID.
6. Click **Add a certificate or secret** in the **Client credentials** field.
7. Click **New client secret**.
8. Copy the client secret from the **Value** field.
9. Go to [Create OAuth connection](#) on page 1827 and complete the remaining steps to create an OAuth connection with the above details.

SharePoint authenticate action

Use the **Authenticate** action to connect to your SharePoint domain. After the authentication is successful, you can use the other command actions to perform various operations in SharePoint.

- You must have the client ID and client secret generated for your SharePoint domain. To generate the client details, see [SharePoint package](#) on page 2907.
- You must have the Bot Creator role for your Automation Anywhere Control Room to use the SharePoint package in a bot.

You can authenticate to either a cloud or on-premises SharePoint domain. To access your cloud SharePoint domain, log in to your SharePoint account from a web browser. SharePoint on-premises is an in-house version of SharePoint installed on your local server.

You can use different connection methods to connect to SharePoint:

- **OAuth2 - Client Credentials:** Use this connection method by providing the SharePoint credentials.
 - **Control room OAuth connection:** Use this connection method by creating an OAuth connection and storing it in the Control Room.
1. Log in to the Automation Anywhere Control Room.
 2. You can create a new bot or modify an existing bot. For more details, see [Create your first bot](#) on page 1429.
 3. From the **Actions** pane, select **SharePoint > Authenticate** and place it under the start of the bot flow.

SharePoint: Authenticate

Authenticates via SharePoint API to generate an access token
Required bot agent version: 21.250 or above

Authentication type

4 OAuth2 - Client Credentials (SharePoint App-Only) ▾

Client ID
Credential Variable Insecure string

” ” [x]

Client secret
Credential Variable Insecure string

” ” [x]

Tenant ID
Credential Variable Insecure string

” ” [x]

Domain

5 Cloud Custom/on premises

Subdomain
” automationanywherestore [x]
Https://{subdomain}.sharepoint.com

Site name (optional)
” AutomationAnywhere [x]
https://{subdomain}.sharepoint.com/site/{SiteName}

6 Teams site

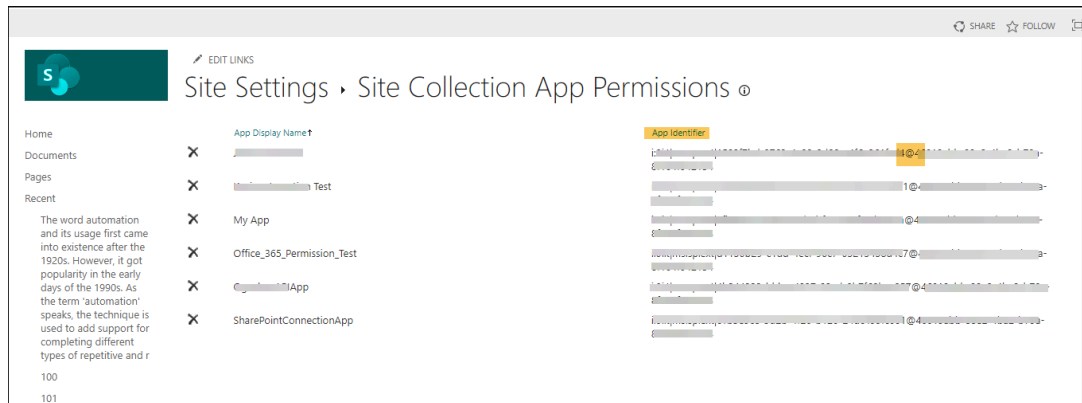

7 Create SharePoint session
Local session Global session Variable

Local session name can only be used in this bot.

” Default [x]

4. In the **Authentication Type** field, select the authentication method from the drop down.
5. To connect using **OAuth2 - Client Credentials**, complete the following steps:
 - a) In the **Client ID** field, enter the client ID copied from SharePoint. This example uses **Insecure string** however, you can use **Credential** or **Variable** options for better security.
 - b) In the **Client secret** field, enter the client secret copied from SharePoint.

- c) In the **Tenant ID** field, enter the tenant ID copied from SharePoint. To view the tenant ID, go to https://{your_sharepoint_domain}/_layouts/15/AppPrincipals.aspx. Replace {your_sharepoint_domain} with your SharePoint domain name. In the **App identifier** column, the tenant ID is displayed after the @ symbol as shown in the following image:

Note: You can use one of the following options to specify the **Client ID/Client secret/Tenant ID**:

- **Credential:** Enables you to use a value in the Credential Vault that contains information about the client ID/client secret/tenant ID.
- **Variable:** Enables you to use a credential variable that contains information about the client ID/client secret/tenant ID.
- **Insecure string:** Enables you to enter the client ID/client secret/tenant ID as a string.

6. To connect using **Control room OAuth connection**, pick a custom connection you have created and stored in the Control Room. For more details, see [Integrate OAuth with Control Room](#) on page 1824.

7. In the **Domain** field, select one of the following options.

- **Cloud:**
 - Enter the SharePoint subdomain name.
 - Enter the site name.

Note: The site name you provide in the authentication action will be the default site selected for the other actions in this package. You can provide a different site name for the individual actions as well.

- **Custom/on premises:**
 - Enter your SharePoint on-premises URL in the format `https://{url}` (for example: `https://sharepoint.automationanywhere.com/`).
 - Enter the site name.

Note: The site name you provide in the authentication action will be the default site selected for the other actions in this package. You can provide a different site name for the individual actions as well.

8. Select the **Teams site** check box to connect to a SharePoint teams site. By enabling the Teams site checkbox, you can connect to Sharepoint's Team based managed paths and perform operations.

Note:

A managed path is a location within a SharePoint web application in which you can have site collections. Managed paths allow you to specify a path users will use to access your site contents. By default, SharePoint Online provides two managed paths:

- **sites:** This managed path is used for creating site collections, and the URLs for site collections created using this path follow this format: `https://<yourdomain>.sharepoint.com/sites/<sitename>`.
- **teams:** This managed path is used for creating modern team sites, and the URLs for team sites created using this path follow this format: `https://<yourdomain>.sharepoint.com/teams/<sitename>`.

-
9. In the **Create SharePoint session** field, select one of the following options:

- **Local session:** You can use the local session name only for the current bot.
- **Global session:** You can use the global session name in other parent and child bots.
- **Variable:** You can add the session name to a variable and use the variable in other actions.

You are successfully authenticated to the SharePoint domain.

SharePoint folder and file

Use the **Folder and file** actions to perform various operations in your SharePoint site. You can create, get details, delete, or rename folders in a specific SharePoint site. You can also upload, delete, download, and get files in a specified folder.

Folder and file actions in SharePoint package

The SharePoint package includes the following folder and file actions:

Action	Description
SharePoint create folder Action	Use the Create folder action to create a new folder in the specified path in your SharePoint site.
SharePoint delete folder Action	Use the Delete folder action to delete a folder from the specified path in your SharePoint site.
SharePoint get folder Action	Use the Get folder action to retrieve details of a specific folder or all folders in the specified path in your SharePoint site.
SharePoint rename folder Action	Use the Rename folder action to retrieve details of a specific folder or all folders in the specified path in your SharePoint site.
SharePoint delete file Action	Use the Delete file action to delete a file from the specified path in your SharePoint site.
SharePoint download file Action	Use the Download file action to download a file from a folder in your SharePoint site.

Action	Description
SharePoint get files Action	Use the Get file(s) action to retrieve one or more file details from your SharePoint site.
SharePoint upload file Action	Use the Upload file action to upload a file to a folder in your SharePoint site.

SharePoint create folder action

Use the **Create folder** action to create a new folder in the specified path in your SharePoint site.

- Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.
- You must create a SharePoint site to store the folder and file data. For more details, see [Create new app in SharePoint](#).

1. From the **Actions** pane, select **SharePoint > Folder and file > Create folder** and place it in the canvas.

SharePoint: Create folder

Creates a folder in the path provided when the correct information is entered
Required bot agent version: 21.250 or above

Site
2 Default site Other site

Document library path
3 (x)

Folder path must not be greater than 400 chars

Folder name
4 (x)

Folder name must not be greater than 260 chars

Session
 Session name Variable

5 (x)

The name you gave the session when you opened it.

Folder path
6 (x)

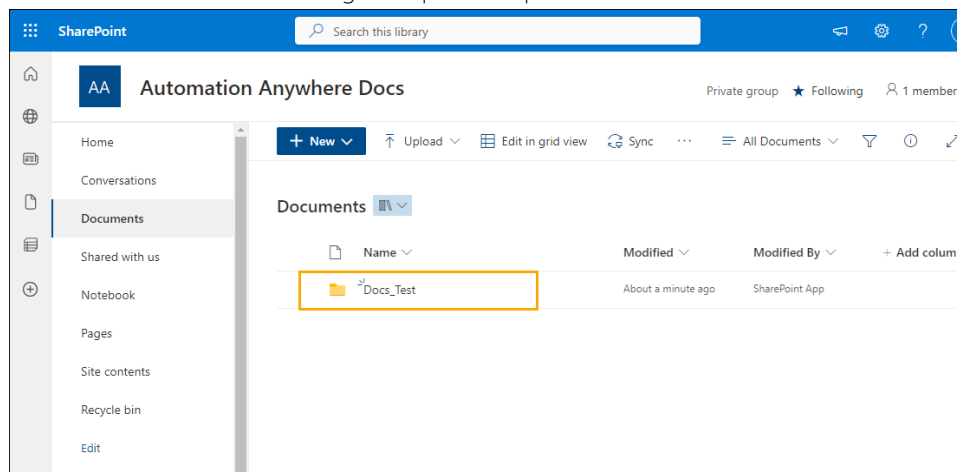

2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site to create a folder, specify the different site name.
3. In the **Document library field**, specify the path where the folder must be created.

Note: You can create folders only within the **Document library** type of the site contents. To view the path name, hover over one of the document library names and view the folder path as shown in the following image:

4. In the **Folder name** field, specify the folder name you want to create.
5. In the **Session** field, select one of the following options:
 - **Session name**: The name you provided for the session during authentication.
 - **Variable**: Select a variable which contains the session name.
6. In the **Folder path** field, select a variable to store the created folder path name.

A new folder is created using the specified path.

SharePoint delete folder action

Use the **Delete folder** action to delete a folder in the specified path in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > Folder and file > Delete folder** and place it in the canvas.
2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered as the default site.
 - **Other site:** If you want to choose a different site, specify the different site name.
3. In the **Folder path** field, specify the folder path followed by the folder name.
4. In the **Session** field, select one of the following options:
 - **Session name:** The name you have provided for the session during authentication.
 - **Variable:** Select a variable which contains the session name.

The specified folder is deleted.

SharePoint get folder action

Use the **Get folder** action to retrieve details of a specific folder or all folders in the specified path in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > Folder and file > Get folder** and place it in the canvas.

SharePoint: Get folder(s)

The action should return a list of folders from SharePoint when the correct inputs have been entered

Required bot agent version: 21.250 or above

Site

2 Default site Other site

Folder path

3 SiteAssets/Docs_Test (x)

Example: SiteAssets/FolderName

Get all / filter by

4 All folders

Session

Session name Variable

5 Default (x)

The name you gave the session when you opened it.

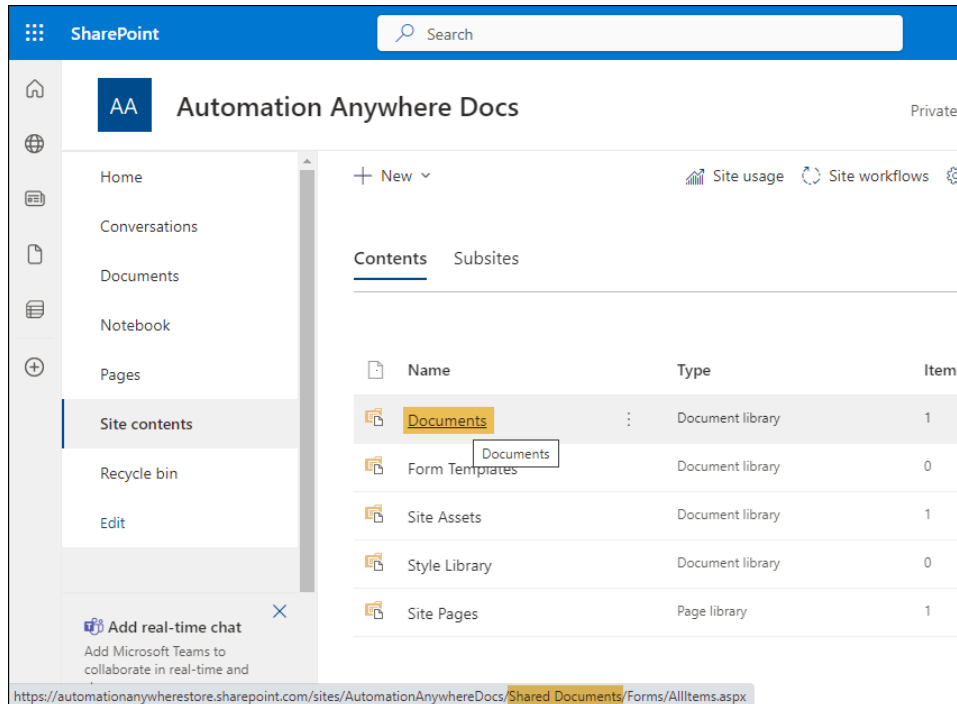

List of folders

7 Get-folders (x)

2. In the **Site** field, select one of the following options:

- **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different, specify the different site name.
3. In the **Folder path** field, specify the folder path followed by the folder name.

Note: You can view the folder path in your SharePoint site. To view the root folder name, hover over one of the document library names and view the folder path as shown in the following image:

4. In the **Get all / filter by** field, select one of the following options:
- **All folders:** Retrieve details of all the folders in the specified path.
 - **Folder name:** Specify a folder name to retrieve details of this folder.
5. In the **Session** field, select one of the following options:
- **Session name:** The name you provided for the session during authentication.
 - **Variable:** Select a variable which contains the session name.
6. In the **List of folders** field, select a variable to store the retrieved folder data.

The specified folder details is retrieved and stored in the variable.

Note: The output is retrieved as a list of type `.` To read an individual record (row) in this list, you need to loop through all the dictionary items using the `read` action and read or extract the records (rows) individually. For example, the output of `get multiple records` is saved in the variable `list_of_records_any`. If the variable contains five

records, then each record is passed to the Loop action to be processed one at a

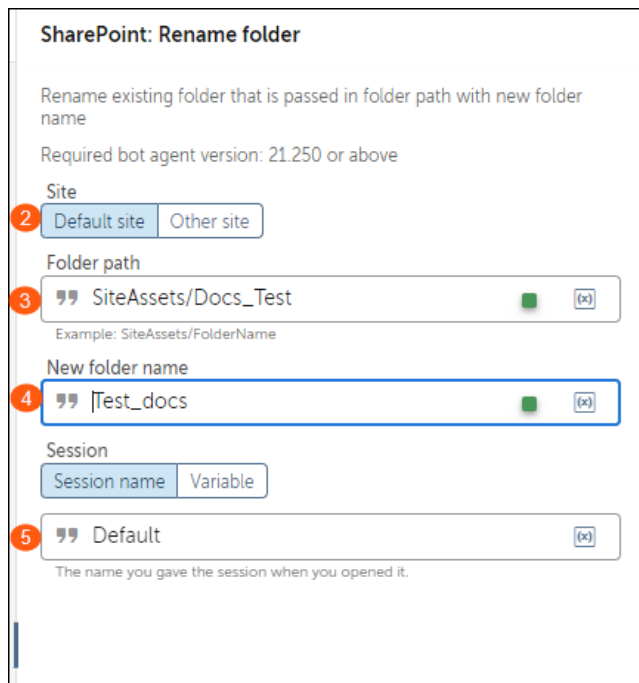

time.

SharePoint rename folder action

Use the **Rename folder** action to rename a specific folder in the specified path in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > Folder and file > Rename folder** and place it in the canvas.

2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site, specify the different site name.
3. In the **Folder path** field, specify the folder path followed by the folder name.
4. In the **New folder name** field, specify the new folder name you want to rename the folder to.

5. In the **Session** field, select one of the following options:
 - **Session name**: The name you provided for the session during authentication.
 - **Variable**: Select a variable which contains the session name.

The specified folder is renamed with the new folder name.

SharePoint delete file action

Use the **Delete file** action to delete a file in the specified path in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > Folder and file > Delete file** and place it in the canvas.
2. In the **Site** field, select one of the following options:
 - **Default site**: The site name used during authentication is considered the default site.
 - **Other site**: If you want to choose a different site, specify the different site name.
3. In the **File path** field, specify the folder path followed by the file name.
4. In the **Session** field, select one of the following options:
 - **Session name**: The name you provided for the session during authentication.
 - **Variable**: Select a variable which contains the session name.

The specified file is deleted from the folder.

SharePoint download file action

Use the **Download file** action to download a file from a folder in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > Folder and file > Download file** and place it in the canvas.

SharePoint: Download file

Download the file to the destination folder provided when the correct information is entered

Required bot agent version: 21.250 or above

Site

2 Default site Other site

File path

3 " Shared Documents/Test_docs/Test File (x)

Example: SiteAssets/FileName.txt

Destination folder

4 " C:\Users\prarthana.reddy\Downloads (x)

Session

Session name Variable

5 " Default (x)

The name you gave the session when you opened it.

File details

6 " filedownload (x)

2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site, specify the different site name.
3. In the **File path** field, specify the file path followed by the file name.

Note: The file path must contain the main **Document Library** folder name followed by the parent folder (if any) and the file name (for example: `Shared Documents/Test_docs/Test File`). You must specify the file extension only if the file name contains the extension in SharePoint.

4. In the **Destination folder** field, specify the local folder path where you want to download the file.
5. In the **Session** field, select one of the following options:
 - **Session name:** The name you provided for the session during authentication.
 - **Variable:** Select a variable which contains the session name.
6. In the **File details** field, select one of the following options:
 - **Multiple variables:** Add a key-value pair to store the file details.
 - **Dictionary:** Select a dictionary variable to store the file details.

The specified file is downloaded to the destination folder.

SharePoint get files action

Use the **Get file(s)** action to retrieve one or more file details from your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > Folder and file > Get file(s)** and place it in the canvas.

SharePoint: Get file(s)

Get list of files from SharePoint when the correct inputs have been entered

Required bot agent version: 21.250 or above

Site

2 Default site Other site

Folder path

3

Example: SiteAssets/FolderName

Get all / filter by

4

2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site, specify the different site name.
3. In the **Folder path** field, specify the main **Document Library** folder name followed by the parent folder.
4. In the **Get all / filter by** field, select one of the following options:

- **All files:** Select this option to retrieve all file details available in your SharePoint site.
 - **File name:** Specify a file name to retrieve the file details.
 - **File extension:** Specify a file extension to retrieve all file details with the specified extension.
5. In the **Session** field, select one of the following options:
 - **Session name:** The name you provided for the session during authentication.
 - **Variable:** Select a variable which contains the session name.
 6. In the **List of files** field, select a variable to store the file details.

One or more file details are retrieved and stored in the variable.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

time.

SharePoint upload file action

Use the **Upload file** action to upload a file to a folder in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

Note: The maximum file size that can be uploaded is 25 MB.

1. From the **Actions** pane, select **SharePoint > Folder and file > Upload file** and place it in the canvas.

SharePoint: Upload file

Creates a file in the path provided when the correct information is entered

Session name Variable

6 (x)

The name you gave the session when you opened it.

File path

7 (x)

2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site, specify the different site name.
3. In the **Folder path** field, specify the main **Document Library** folder name followed by the parent folder.
4. In the **File name** field, specify the name of the file that will be displayed in SharePoint. You can provide the file name with or without an extension.
5. In the **File content** field, select one of the following options:
 - **Control room file:** Choose a file that is available in the Control Room.
 - **Desktop file:** Browse and select a file from your local system.
 - **Variable:** Insert a variable that contains the file path.
6. In the **Session** field, select one of the following options:
 - **Session name:** The name you provided for the session during authentication.

- **Variable:** Select a variable which contains the session name.

7. In the **File path** field, select a variable to store the file path details.

The specified file is uploaded to the destination folder.

SharePoint list and list items

Use the **List and list item** actions to perform various operations in your SharePoint site. You can create, get, delete, or update list and list items in a specific SharePoint site.

List and list item actions in SharePoint package

The SharePoint package includes the following list and list item actions:

Action	Description
SharePoint create list Action	Use the Create list action to create a new list in your SharePoint site.
SharePoint delete list Action	Use the Delete list action to delete a list from your SharePoint site.
SharePoint get list Action	Use the Get list action to retrieve the list details from your SharePoint site.
SharePoint update list Action	Use the Update list action to update a list name in your SharePoint site.
SharePoint create list item Action	Use the Create list item action to create a list item within a list in your SharePoint site.
SharePoint delete list item Action	Use the Delete list item action to delete a list item from a list in your SharePoint site.
SharePoint get list item Action	Use the Get list item action to retrieve the list item details from a list in your SharePoint site.
SharePoint update list item Action	Use the Update list item action to update a list item value within a list in your SharePoint site.
SharePoint upload list image Action	Use the Upload list image action to upload an image file to a list item in your SharePoint site.
SharePoint delete list attachment Action	Use the Delete list attachment action to delete an attachment from a list item in your SharePoint site.
SharePoint download list attachment Action	Use the Download list attachment action to download an attachment from a list item in your SharePoint site.
SharePoint upload list attachment Action	Use the Upload list attachment action to upload an attachment to a list item in your SharePoint site.

SharePoint create list action

Use the **Create list** action to create a new list in your SharePoint site.

- Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.
- You must create a SharePoint site to store the list. For more details, see [Create new app in SharePoint](#).

1. From the **Actions** pane, select **SharePoint > List and list items > Create list** and place it in the canvas.

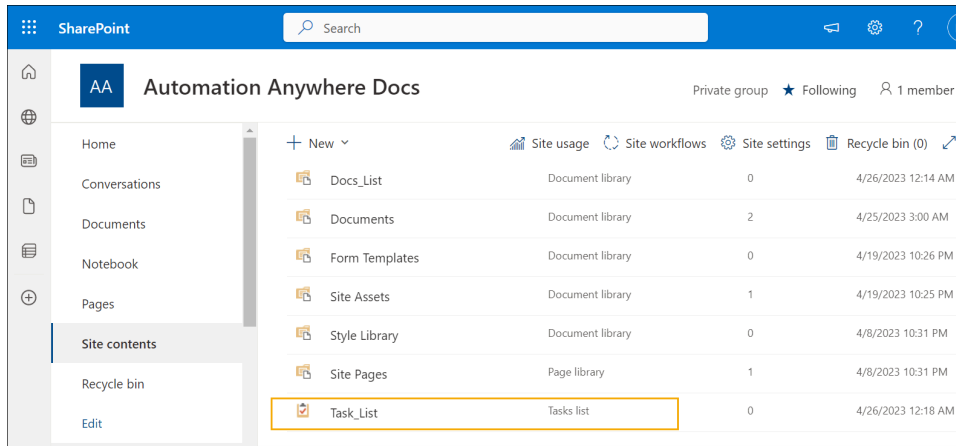

The screenshot shows the configuration interface for the 'SharePoint: Create list' action. The form includes the following fields and options:

- Site:** Two buttons, 'Default site' (highlighted with a red circle 2) and 'Other site'.
- List name:** A text input field containing 'Task_List' (highlighted with a red circle 3).
- Template:** A dropdown menu with 'Genericlist' selected (highlighted with a red circle 4).
- Description (optional):** A text input field containing 'A list of items for documents' (highlighted with a red circle 5).
- Session:** Two buttons, 'Session name' (highlighted with a red circle 6) and 'Variable'.
- Session name:** A text input field containing 'Default' (highlighted with a red circle 6).
- List ID (optional):** A dropdown menu with 'List_ID' selected (highlighted with a red circle 7).

2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site to create a folder, specify the different site name.
3. In the **List name** field, specify a name for the new list.

4. In the **Template** field, select a template from the drop-down list. For more information, see [SharePoint templates](#).
5. In the **Description** field, provide a description for the list.
6. In the **Session** field, select one of the following options:
 - **Session name**: The name you provided for the session during authentication.
 - **Variable**: Select a variable which contains the session name.
7. In the **List ID** field, select a variable to store the created list ID.

A new list is created in SharePoint.

SharePoint delete list action

Use the **Delete list** action to delete a list from your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > List and list item > Delete list** and place it in the canvas.
2. In the **Site** field, select one of the following options:
 - **Default site**: The site name used during authentication is considered the default site.
 - **Other site**: If you want to choose a different site, specify the different site name.
3. In the **List name** field, specify the list name you want to delete.
4. In the **Session** field, select one of the following options:
 - **Session name**: The name you provided for the session during authentication.
 - **Variable**: Select a variable which contains the session name.

The specified list is deleted.

SharePoint get list action

Use the **Get list** action to retrieve the list details from your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > List and list items > Get list** and place it in the canvas.

2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site, specify the different site name.
3. In the **Filter** field, select one of the following options:
 - **All lists:** Retrieve details of all the lists in your SharePoint site.
 - **ID:** Specify the list ID to retrieve details of this specific list.
 - **Name:** Specify a list name to retrieve details of this specific list.
4. In the **Session** field, select one of the following options:
 - **Session name:** The name you provided for the session during authentication.
 - **Variable:** Select a variable which contains the session name.

5. In the **Matched records** field, select a variable to store the list details.

The specified list details are retrieved and stored in the variable.

Note: The output is retrieved as a list of type `List`. To read an individual record (row) in this list, you need to loop through all the dictionary items using the `Loop` action and read or extract the records (rows) individually. For example, the output of `get multiple records` is saved in the variable `list_of_records_any`. If the variable contains five records, then each record is passed to the `Loop` action to be processed one at a

Default value (optional)	This list is empty

time.

SharePoint update list action

Use the **Update list** action to update a list name in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > List and list items > Update list** and place it in the canvas.
2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site, specify the different site name.
3. In the **Current list name** field, specify the existing name for the list.
4. In the **New list name** field, specify a new name for the list.
5. In the **Description** field, add a description for the list.
6. In the **Session** field, select one of the following options:
 - **Session name:** The name you provided for the session during authentication.
 - **Variable:** Select a variable which contains the session name.

The list is updated with the specified new name.

SharePoint create list item action

Use the **Create list item** action to create a list item within a list in your SharePoint site.

- Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

- You must create a list in your SharePoint site. For more details, see [SharePoint create list action](#) on page 2926.
- From the **Actions** pane, select **SharePoint > List and list items > Create list item** and place it in the canvas.

 - **Session name:** The name you provided for the session during authentication.
 - **Variable:** Select a variable which contains the session name.

The list image is successfully uploaded to the specified column in your SharePoint list.

SharePoint delete list attachment action

Use the **Delete list attachment** action to delete an attachment from a list item in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > List and list items > Delete list attachment** and place it in the canvas.
2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site, specify the different site name.
3. In the **List name** field, specify a list name or select a variable that contains the list name.
4. In the **List item ID** field, specify a list item ID or select a variable that contains the list item ID.
5. In the **Attachment name** field, specify the attachment name or select a variable that contains the attachment name.
6. In the **Session** field, select one of the following options:
 - **Session name:** The name you provided for the session during authentication.
 - **Variable:** Select a variable which contains the session name.

The attachment is successfully deleted from the specified list in your SharePoint site.

SharePoint download list attachment action

Use the **Download list attachment** action to download an attachment from a list item in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

1. From the **Actions** pane, select **SharePoint > List and list items > Download list attachment** and place it in the canvas.
2. In the **Site** field, select one of the following options:
 - **Default site:** The site name used during authentication is considered the default site.
 - **Other site:** If you want to choose a different site, specify the different site name.
3. In the **List name** field, specify a list name or select a variable that contains the list name.
4. In the **List item ID** field, specify a list item ID or select a variable that contains the list item ID.
5. In the **Destination folder** field, specify the folder path where you want to download the attachment.
6. In the **Session** field, select one of the following options:
 - **Session name:** The name you provided for the session during authentication.
 - **Variable:** Select a variable which contains the session name.

The attachment is successfully downloaded from the specified list in your SharePoint site.

SharePoint upload list attachment action

Use the **Upload list attachment** action to upload an attachment to a list item in your SharePoint site.

Ensure that you are authenticated before initiating any SharePoint action. For more details, see [SharePoint authenticate action](#) on page 2911.

Review the updates in released versions of the Simulate keystrokes package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using Keystrokes action

Use the **Keystrokes** action to simulate keystrokes.

Follow these steps to add a **Keystrokes** action:

1. In the Actions palette, double-click or drag the **Keystrokes** action from the **Keystrokes** package.
2. Specify the window in which to capture an object.
Choose from the **Application**, **Browser**, or **Variable** tab.

Option	Description
Application	Select from a list of currently active windows. This option shows a list of all the application and browser windows that are open on the Bot Creator device.
Browser	Select from a list of supported browser tabs. <hr/> Note: This option supports , Chromium-based , and browsers. For all other browsers, use the Application option. <hr/>
Variable	Select an existing window variable to specify the title of the application window title.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*)-Notepad)` for all window title names starting with `((\w*)-Notepad)`, or use **Pattern** value as `((\w)\s)*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

3. Optional: Select the **Resize window** option to specify the window dimensions.

This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.

- If the window is maximized when you record the task, this option is not selected.
- If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

4. In the **Keystrokes**, select a radio button:

- **Enter keystrokes here or use the on-screen keyboard:** Type or use the keyboard to enter keystrokes.
- **Select a credential:** Uses a password stored in the Credential Vault.

Note: A new key named **Return** has been added to the virtual keyboard to replace the Enter functionality and the Enter key in the Number pad has been renamed to **Num Enter**. As a result, the Return key is the main Enter key on the keyboard.

5. Optional: : In the **Delay between each keystroke in ms** field, the delay time.

Note: The default is set to 10 milliseconds.

6. Click **Save**.

SNMP package

The SNMP package allows you to automate network management tasks, such as retrieving and modifying data, and sending notification messages.

Simple Network Management Protocol (SNMP) is used to find the network management component on one or more computers and the managed component on multiple network devices.

The Automation Anywhere SNMP action offers powerful network management. Using this action, users can easily monitor network devices configured with SNMP agent software. Network devices such as servers, workstations, printers, routers, bridges, and hubs, as well as services such as Dynamic Host Configuration Protocol (DHCP) or Windows Internet Name Service (WINS) can be monitored.

Actions in the SNMP package

The SNMP package includes the following actions:

Action	Description
Get	See Get action on page 2944
Get next	See Get next action on page 2946
Send trap	See Send trap action on page 2948

Action	Description
Set	See Set action on page 2950
Walk	See Set action on page 2950

Use the [Active Directory](#) package to automate actions in the Active Directory. An Active Directory is a directory service provided by Microsoft to assist the admin in managing users across a group or organization.

[Printer package](#) on page 2775

Use the actions in the [Printer](#) package to automate retrieving and setting the default printer and removing a printer from the list of available printers.

[SNMP package updates](#) on page 906

Review the updates in released versions of the [SNMP](#) package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Get action

Use the **Get** action in the [SNMP](#) package to retrieve data of an object that is managed by SNMP agent.

1. In the [Actions](#) palette, double-click or drag the **Get** action from the [SNMP](#) package.
2. In the **Agent** field, enter details of the device on which the SNMP agent is available.
3. Click the **SNMP Version** drop-down menu to select one of the following options to specify the SNMP version that must be used:

Option	Action
V1	Specify the community string you want to use in the Community field.
V2C	Specify the community string you want to use in the Community field.

Option	Action
V3	<p>Specify the community string you want to use in the Community field.</p> <p>Click the Authentication level drop-down menu to specify one of the following level of authentication:</p> <ul style="list-style-type: none"> • None: Authentication will not be used. • Authentication Only: Enables you to use authentication only. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. • Authentication and privacy: Enables you to use authentication and privacy. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. c) Click Privacy method drop-down menu and select DES or AES to specify the privacy method you want to use. d) In the Private key field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use.

4. In the **Object ID** field, specify the ID of the object for which you want to retrieve details.
5. Use the **Data type** field to select one of the following options to specify the format in which you want to retrieve details of the object:
 - **ASCII**
 - **Hex**
6. Click the **SNMP advanced options** drop-down menu and enter the values in the following fields:
 - **Timeout(ms)**: Specify the time (in milliseconds) for the action to wait before generating an error.
 - **Remote port**: Specify the port number of the remote device.
 - **Retries**: Specify the maximum number of times the action must try to retrieve the details.
7. In the **Log file** field, click one of the following tabs:
 - **Control Room file**: To select a file that is available on the Control Room to store the result.
Click **Choose** to select a file.
 - **Desktop file**: To select a file that is available on a device to store the result.
Click **Browse** to locate and select a file.
 - **Variable**: To select a variable by specifying the file location that you want to use to store the result.
8. Select a string variable from the **Assigned to** list.
9. Click **Save**.

Get next action

Use the **Get next** action in the SNMP package to retrieve data of the next object that is managed by an SNMP agent.

1. In the **Actions** palette, double-click or drag the **Get next** action from the SNMP package.
2. In the **Agent** field, enter details of the device on which the SNMP agent is available.
3. Click the **SNMP Version** drop-down menu to select one of the following options to specify the SNMP version that must be used:

Option	Action
V1	Specify the community string you want to use in the Community field.
V2C	Specify the community string you want to use in the Community field.

Option	Action
V3	<p>Specify the community string you want to use in the Community field.</p> <p>Click the Authentication level drop-down menu to specify one of the following level of authentication:</p> <ul style="list-style-type: none"> • None: Authentication will not be used. • Authentication Only: Enables you to use authentication only. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. • Authentication and privacy: Enables you to use authentication and privacy. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. c) Click Privacy method drop-down menu and select DES or AES to specify the privacy method you want to use. d) In the Private key field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use.

4. In the **Object ID** field, specify the ID of the object for which you want to retrieve details.
5. Use the **Data type** field to select one of the following options to specify the format in which you want to retrieve details of the object:
 - **ASCII**
 - **Hex**
6. Click the **SNMP advanced options** drop-down menu and enter the values in the following fields:
 - **Timeout(ms)**: Specify the time (in milliseconds) for the action to wait before generating an error.
 - **Remote port**: Specify the port number of the remote device.
 - **Retries**: Specify the maximum number of times the action must try to retrieve the details.
7. In the **Log file** field, click one of the following tabs:
 - **Control Room file**: To select a file that is available on the Control Room to store the result.
Click **Choose** to select a file.
 - **Desktop file**: To select a file that is available on a device to store the result.
Click **Browse** to locate and select a file.
 - **Variable**: To select a variable by specifying the file location that you want to use to store the result.
8. Select a string variable from the **Assigned to** list.
9. Click **Save**.

Send trap action

Use the **Send trap** action in the SNMP package to send messages to the SNMP manager from an SNMP agent. These messages are sent by an SNMP agent whenever certain events occur, such as a system restart.

1. In the **Actions** palette, double-click or drag the **Send trap** action from the SNMP package.
2. In the **Agent** field, enter details of the device on which the SNMP agent is available.
3. Click the **SNMP Version** drop-down menu to select one of the following options to specify the SNMP version that must be used:

Option	Action
V1	Specify the community string you want to use in the Community field.
V2C	Specify the community string you want to use in the Community field.

Option	Action
V3	<p>Specify the community string you want to use in the Community field.</p> <p>Click the Authentication level drop-down menu to specify one of the following level of authentication:</p> <ul style="list-style-type: none"> • None: Authentication will not be used. • Authentication Only: Enables you to use authentication only. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. • Authentication and privacy: Enables you to use authentication and privacy. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. c) Click Privacy method drop-down menu and select DES or AES to specify the privacy method you want to use. d) In the Private key field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use.

4. In the **Object ID** field, specify the ID of the object for which you want to retrieve details.
5. Optional: In the **Authorative ID** field, specify the ID of the SNMP manager that will receive the notification.

Important: If you have selected **V3** from the **SNMP Version** list, you must provide a value for **Authorative ID**.

6. Select an option from the **Select trap type** list to specify the type of trap you want to send.
 - **Cold start:** Occurs when the SNMP agent initializes its configuration tables.
 - **Warm start:** Occurs when the SNMP agent reinitializes its configuration tables.
 - **Link down:** Occurs when the state of a network adapter on the SNMP agent changes from up to down.
 - **Link up:** Occurs when the state of a network adapter on the SNMP agent changes from down to up.
 - **Authentication fail:** Occurs when the SNMP agent receives a message from an SNMP manager with an invalid community name.
 - **EGP neighbour loss:** Occurs when the SNMP agent cannot communicate with its Exterior Gateway Protocol (EGP) peer.
 - **Enterprise specific:** Occurs when specific error conditions and error codes are defined in the system. The user provides a trap-specific number for this option.
7. Click the **SNMP advanced options** drop-down menu and enter the values in the following fields:
 - **Timeout(ms):** Specify the time (in milliseconds) for the action to wait before generating an error.
 - **Remote port:** Specify the port number of the remote device.
 - **Retries:** Specify the maximum number of times the action must try to retrieve the details.
8. In the **Log file** field, click one of the following tabs:
 - **Control Room file:** To select a file that is available on the Control Room to store the result.
Click **Choose** to select a file.
 - **Desktop file:** To select a file that is available on a device to store the result.
Click **Browse** to locate and select a file.
 - **Variable:** To select a variable by specifying the file location that you want to use to store the result.
9. Click **Save**.

Set action

Use the **Set** action in the SNMP package to set a value for an object managed by the SNMP agent.

1. In the **Actions** palette, double-click or drag the **Set** action from the SNMP package.
2. In the **Agent** field, enter details of the device on which the SNMP agent is available.
3. Click the **SNMP Version** drop-down menu to select one of the following options to specify the SNMP version that must be used:

Option	Action
V1	Specify the community string you want to use in the Community field.
V2C	Specify the community string you want to use in the Community field.

Option	Action
V3	<p>Specify the community string you want to use in the Community field.</p> <p>Click the Authentication level drop-down menu to specify one of the following level of authentication:</p> <ul style="list-style-type: none"> • None: Authentication will not be used. • Authentication Only: Enables you to use authentication only. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. • Authentication and privacy: Enables you to use authentication and privacy. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. c) Click Privacy method drop-down menu and select DES or AES to specify the privacy method you want to use. d) In the Private key field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use.

4. In the **Object ID** field, specify the ID of the object for which you want to retrieve details.
5. From the **Value type** list, select an option to specify the value you want to set.
 - **OctetString**
 - **Integer**
 - **Gauge**
 - **TimeTicks**
 - **IP**
 - **ObjectID**
 - **OctetByteString**
 - **OctetDecimalByteString**
 - **NULL**
6. In the **Set value** field, specify the value you want to set.
7. Click the **SNMP advanced options** drop-down menu and enter the values in the following fields:
 - **Timeout(ms)**: Specify the time (in milliseconds) for the action to wait before generating an error.
 - **Remote port**: Specify the port number of the remote device.
 - **Retries**: Specify the maximum number of times the action must try to retrieve the details.
8. In the **Log file** field, click one of the following tabs:
 - **Control Room file**: To select a file that is available on the Control Room to store the result.
Click **Choose** to select a file.
 - **Desktop file**: To select a file that is available on a device to store the result.
Click **Browse** to locate and select a file.
 - **Variable**: To select a variable by specifying the file location that you want to use to store the result.
9. Click **Save**.

Walk action

Use the **Walk** action in the SNMP package to set up a collection of information about all the devices available on all the connected nodes or subtree.

1. In the **Actions** palette, double-click or drag the **Walk** action from the SNMP package.
2. In the **Agent** field, enter details of the device on which the SNMP agent is available.
3. Click the **SNMP Version** drop-down menu to select one of the following options to specify the SNMP version that must be used:

Option	Action
V1	Specify the community string you want to use in the Community field.
V2C	Specify the community string you want to use in the Community field.

Option	Action
V3	<p>Specify the community string you want to use in the Community field.</p> <p>Click the Authentication level drop-down menu to specify one of the following level of authentication:</p> <ul style="list-style-type: none"> • None: Authentication will not be used. • Authentication Only: Enables you to use authentication only. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. • Authentication and privacy: Enables you to use authentication and privacy. <ul style="list-style-type: none"> a) Select MD5 or SHA from the Authentication method list to specify the authentication method you want to use. b) In the Password field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use. c) Click Privacy method drop-down menu and select DES or AES to specify the privacy method you want to use. d) In the Private key field, click one of the following tabs: <ul style="list-style-type: none"> • Credential: To use a value from the Credential Vault. (Optional) Click Pick to choose a credential. • Variable: To use a credential variable. • Insecure string: To manually specify the value you want to use.

4. In the **Object ID** field, specify the ID of the object for which you want to retrieve details.
5. Use the **Data type** field to select one of the following options to specify the format in which you want to retrieve details of the object:
 - **ASCII**
 - **Hex**
6. In the **Walk type** section, select an option to specify the scope from which to collect information.
 - **All**: Displays the variables that are equal to the specified OID for the given tree type structure.
 - **Within**: All variables in the sub-tree below the given OID are queried.
7. Click the **SNMP advanced options** drop-down menu and enter the values in the following fields:
 - **Timeout(ms)**: Specify the time (in milliseconds) for the action to wait before generating an error.
 - **Remote port**: Specify the port number of the remote device.
 - **Retries**: Specify the maximum number of times the action must try to retrieve the details.
8. In the **Log file** field, click one of the following tabs:
 - **Control Room file**: To select a file that is available on the Control Room to store the result.
Click **Choose** to select a file.
 - **Desktop file**: To select a file that is available on a device to store the result.
Click **Browse** to locate and select a file.
 - **Variable**: To select a variable by specifying the file location that you want to use to store the result.
9. Select a string variable from the **Assigned to** list.
10. Click **Save**.

SOAP Web Service package

Use the **SOAP web service** action from the SOAP Web Service package to access and exchange information between two systems in XML format.

With SOAP Web Service, you can perform these actions:

- Consume SOAP web services written to provide structured data for further business processing, such as currency conversion, weather reports, and language translation.
- Connect to different existing applications and different platforms, irrespective of any underlying infrastructure requirements.

The SOAP Web Service establishes complete interoperability between clients or applications and the internet, supporting XML-based open standards, such as Web Services Description Language (WSDL), Simple Object Access Protocol (SOAP), and Universal Description Discovery and Integration (UDDI).

Note: Windows Authentication is currently not supported for SOAP Web Service package in Automation 360.

Passing values securely

You can securely pass values from the Credential Vault to the web service by specifying the locker, credential, and attribute in the following supported action fields:

- Custom headers
- Operation parameters
- Raw data: You must select a Credential Vault value that contains the entire parameter as the value.

Proxy support

If your device is configured with a proxy, all outbound requests from this package are routed through the proxy server. See [Connect Bot Agent to a device with a proxy](#) on page 1293.

Note: For an example task about using the SOAP Web Service action, see [Example of using the SOAP web service action](#) on page 3097.

Related tasks

[Example of building a bot that uses credential variables](#) on page 2258

Securely pass values to a bot using credential variables to automate the process of logging in to a bank website.

Related reference

[Credentials and credential variables in the Bot editor](#) on page 2254

Use credentials when building bots to pass sensitive information such as passwords and account numbers. Using credentials separates the sensitive information from the bots and Bot Runners, which reduces the risk of data spillage or unauthorized user access.

[SOAP Web Services package updates](#) on page 907

Review the updates in released versions of packages such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Step package

The `Step` package groups various actions together and runs them in a specific order. You can provide a relevant name for a step to identify the operation performed by the actions included in that step.

Action in the Step package

The `Step` package includes the following action:

Action	Description
Step	<p>Runs a sequence of actions.</p> <ul style="list-style-type: none"> Creates a container for actions without impacting the bot run. Configures actions within the Step action. Runs the arranged actions in a sequential order. Groups various actions for better management. Optional: In the Title field, specify the title.

String package

Use the String package to perform various operations such as comparing two strings, retrieving the string length, or converting a string to uppercase or lowercase.

Actions in the String package

The String package includes the following actions:

Action	Description
Assign	Assign action on page 2958
Extract text	Using Extract text action of String package on page 2960
Compare	Compare action on page 2963
Evaluate variable	Evaluate variable action on page 2963
Find	Using Find action of String package on page 2964
Length	Length action on page 2965
Lowercase	Lowercase action on page 2965
Generate random string	Generate random string action on page 2965
Replace	Using Replace action on page 2966
Reverse	Reverse action on page 2967
Split	Using Split action on page 2967
Substring	Substring action on page 2970
To boolean	To boolean action on page 2971
To locale number	To locale number action on page 2972
To number	To number action on page 2973

Action	Description
Trim	Trim action on page 2975
Uppercase	Uppercase action on page 2975
Import string from text file	Import string from text file action on page 2975

Related tasks

[Using Extract text action of String package](#) on page 2960

Use the **Extract text** action to extract a range of text using logical operators from the source string.

[Using Find action of String package](#) on page 2964

Use the **Find** action to find a substring within the specified string.

[Using Replace action](#) on page 2966

Use the **Replace** action to find a piece of text from the source string and replace it with another text.

[Using Split action](#) on page 2967

Use the **Split** action to split the specified string into multiple strings and store the output in a list variable.

Related reference

[String package updates](#) on page 909

Review the updates in released versions of the String package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Assign action

The **Assign** action in the String package enables you to assign or concatenate strings.

Settings

- Optional: In the **Select the source string variable(s)/value** field, specify the variable or values. This field holds up to 65535 alphanumeric, character, and empty values.

Note:

- To provide a string that includes a dollar sign (\$), you must enter two dollar signs. For example, if you enter `Pay $$5.00`, the output will be `Pay $5.00`.
- The values or variables that you can specify for the String package are predefined. See [Predefined variables](#) on page 2237

-
- In the **Select the destination string variable** field, specify the variable.

Example

Create a sample bot and perform the following steps to concatenate two strings:

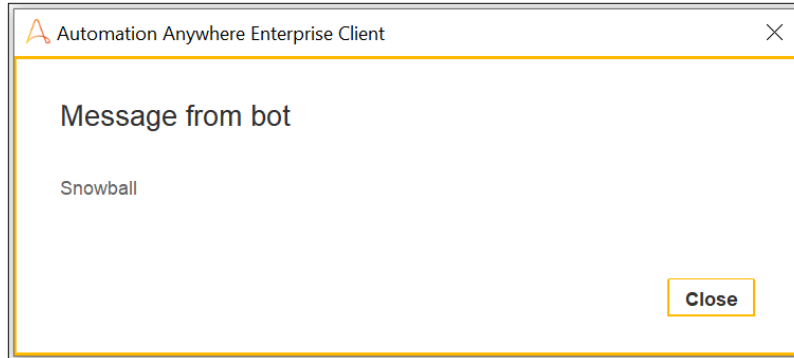

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name: `String_assign`.
 - d) Click **Create and Edit**.

2. Create the user-defined variables using the **Create variable (+)** icon at the top of the **Variables** menu.
 - a) Create a variables of String to hold the values.
 - b) In the Edit variable window, enter the **Name**, select the **Type** and enter the following values:

Name	Type	Value
var1	String	Snow
var2	String	ball

3. To concatenate two strings, from the **Actions** pane, double-click or drag the **String > Assign** action.
 - a) In the **Select the source string variable(s)/ value (optional)** field, select `$var1$$var2$`.
 - b) In the **Select the destination string variable** field, click the **Create variable** icon to create a variable.
 - c) On the **Create variable** window, enter `vassign` in the **Name** field.
 - d) Click **Create and select**.

4. To print the values, double-click or drag the **Message box** action. In the **Enter the message to display** field, enter `$vassign$`.
5. Click **Save** and then **Run**.
The bot concatenates two strings and displays the output as **Snowball**.

Using Extract text action of String package

Use the **Extract text** action to extract a range of text using logical operators from the source string.

Review examples of using **Before**, **After**, and **Before and/or After** options in [Examples of using Extract text action](#) on page 2962.

To extract a substring from the specified source string, do the following:

1. In the **Actions** palette, double-click or drag the **Extract text** action from the **String** package.
2. In the **Source string** field, specify the source string.
3. Specify the text to extract by selecting from the following options:

Option	Steps
Before	<p>Extracts the entire text followed by the value that you have provided in the Start after text field.</p> <p>a) In the Start after text field, enter a string to use as the starting point.</p> <p>b) In the Occurrence field, enter a value to specify the number of occurrences.</p> <p>For example, if the source string is <code>This is a test string which is used to extract specific sub-string</code> and you want to extract the entire text after <code>This</code>. To extract the required text, you must enter <code>This</code> in the Start after text field and <code>1</code> in the Occurrence field. This indicates to the system to extract the text that is available after the first occurrence of <code>This</code> in the source string.</p>

Option	Steps
Before and/or after	<p>Extracts the text between the values provided in the Start after text and the End before text fields.</p> <p>a) In the Start after text field, enter a string to use as the starting point.</p> <p>b) In the OR or AND field, select one of the options:</p> <ul style="list-style-type: none"> • OR: Select to extract text if either of the values specified in the Start after text or the End before text field are available in the source string. • AND: Select to extract text if both the values specified in the Start after text and the End before text fields are available in the source string. <p>c) In the End before text field, specify a string to use as the endpoint for extracting the text.</p> <p>d) In the Occurrence field, enter a value to specify the number of occurrences of the string you have provided in the End before text field.</p> <p>For example, if the source string is <code>This is a test string which is used to extract specific substring and you want to extract the entire text before specific</code>. To extract the required text, you must enter <code>specific</code> in the End before text field and <code>1</code> in the Occurrence field. This indicates to the system to extract the text available before the first occurrence of <code>specific</code> in the source string.</p>
After	<p>Extracts the entire text preceding the value you have provided in the End before text field.</p> <p>a) In the End before text field, specify a string to use as the endpoint for extracting the text.</p> <p>b) In the Occurrence field, enter a value to specify the number of occurrences of the string you have provided in the End before text field.</p> <p>For example, if the source string is <code>This is a test string which is used to extract specific substring and you want to extract the entire text before specific</code>. To extract the required text, you must enter <code>specific</code> in the End before text field and <code>1</code> in the Occurrence field. This indicates to the system to extract the text available before the first occurrence of <code>specific</code> in the source string.</p>

4. In the **If no match found, return** field, select one of the options:
 - **Source String**: Return the source string.
 - **Empty (null) String**: Return the null string if no match is found.
5. In the **When extracting** field, select one of the following options:

- **Match case:** Matches the case of the text in the source string
- **Do not match case:** Does not match the case of the text in the source string

Note: By default, the **Match case** option is selected for all the new and existing bots.

6. In the **Number of characters to get** field, select one of the options:

- **All:** Extracts all characters from the source string.
- **Only:** Specify the exact number of characters to extract from the source string.
- **Up to:** Specify the maximum number of characters that you want to extract from the source string.

Note: This option enables you to provide a maximum limit of the characters that you want to extract. However, it is not mandatory that the source string contain the number of characters that you enter in this field.

For example, the source string has `Date+8` as its value and you want to extract the characters after the string `Date`. You enter 10 in the **Up to** field, to extract 10 characters from the source string that appears after the string `Date`. When you run the bot, the output is `+8` and it returns all the values after the string `Date`.

Note: The value 10 only depicts the maximum number of characters that you want to extract.

7. In the **Trim the extracted text (remove blank spaces)** check box, select to remove blank spaces from the extracted text.
8. In the **Remove Enter from the extracted text** check box, select to remove carriage returns from the extracted text.
9. In the **Assign the output to variable** list, specify the variable.
10. Click **Save**.

Examples of using Extract text action

The **Extract text** action enables you to extract text from a source string. You can extract text that occurs in the range of 1 to 999999 times in a file before, after, or between two strings.

Before option

This option enables you to extract the entire text followed by the value you have provided in the **Start after text** field. You can also extract the text based on the occurrence of the value you have provided in the field.

For example, `a:123a:123b:123c:` is the source string, you can specify `:` in the **Start after text** field and 2 in the **Occurrence** field to extract the string followed by the second occurrence of `:` in the source string. In this example, the extracted text is `123b:123c:`.

After option

This option enables you to extract the entire text preceding the value you have provided in the **End before text** field. You can also extract the text based on the occurrence of the value you have provided in the field.

Note: You can extract text that occurs more than 1000 times in a file and up to a maximum of 999999 times.

For example, `a:123a:123b:123c:` is the source string, you can specify `:` in the **End before text** field and 3 in the **Occurrence** field to extract the string preceding the third occurrence of `:` in the source string. In this example, the extracted text is `a:123a:123b`.

Before and/or after option

This option enables you to extract the text between the values you have provided in the **Start after text** and the **End before text** fields. You can also apply the **AND** or **OR** logical operator. You can select the **AND** operator to extract text only when both conditions specified for the **Before** and **After** options are satisfied. Otherwise, you can select the **OR** operator to extract text only when either of the conditions specified for the **Before** or the **After** option is satisfied.

For example, `a:123a:123b:123c:` is the source string, you can specify `:` in the **Start after text** and **End before text** fields and 2 in the **Occurrence** fields to extract the string after the second and before the fourth occurrence of `:` in the source string. In this example, the extracted text is `123b:123c`.

Compare action

The **Compare** action in the `String` package enables you to compare two strings.

Settings

- In the **Source string** field, specify the source string.
- In the **Compare to string** field, specify the string that the source has to be compared with.
- In the **When comparing** field, select an option:
 - **Match case:** Matches capitalization.
 - **Do not match case:** Does not match capitalization.
- In the **Assign the output to variable** list, specify the Boolean variable.

Evaluate variable action

Use the **Evaluate variable** action in the `String` package to compare the user-specified string variable with the string variables in the bot. If a match is found, the action returns the value of the matching variable.

Settings

- Enter the string variable that you want to find.
- In the **Assign the value to a variable** field, select a string variable to hold the returned value.

Example

Assume you have a bot where you defined a string variable named `$cityname$`. The value of the variable `$cityname$` is set to `Paris`. You can now build a bot and use the **Evaluate variable** action to compare the variable that you create, with an already existing string variable in the bot. If a match is found, then the action returns the value of the matched variable.

1. Create a variable of type string whose value you want to evaluate and name it `var1`.
2. In the Default value field, enter `$cityname$`.

Note: `$cityname$` is the string variable that you have used in the bot.

3. Enter `$var1$` in the **Variable expression** field.
4. On bot execution, the user specified string variable `$var1$` now searches among the variables defined in the bot for the string variable `$cityname$` and if the match is found then the action returns the output value of the matched variable `$cityname$`, that is, `Paris`.

Using Find action of String package

Use the **Find** action to find a substring within the specified string.

This action also enables you to perform a search based on a regular expression. A regular expression is a sequence of characters that define a search pattern. For example, to find all email addresses in the source string, specify the following as a regular expression: `\b[A-Z0-9._%~]+@[A-Z0-9.-]+\.[A-Z]{2,4}\b`.

Note: To search for strings that contain the dollar sign (\$), you must enter the sign twice. Otherwise, the bot interprets the dollar sign as a regular expression character.

To find a substring from the specified string, follow these steps:

1. In the **Actions** palette, double-click or drag the **Find** action from the **String** package.
2. In the **Source string** field, specify the source string.
3. In the **Find string** field, specify the substring.
4. In the **When finding** field, select one of the options:
 - **Match case:** Matches the case of the text.
 - **Do not match case:** Does not match the case of the text.
5. In the **The "find string" is** field, select one of the options:
 - **A regular expression:** The substring is a regular expression
 - **Not a regular expression:** The substring is not a regular expression.
6. Optional: In the **Start from** field, specify the starting point.

For example, you want to replace Red in the source string with Blue in a paragraph. Red is in 10 instances in the paragraph and you want to replace only the third occurrence. Enter 3 in the **Start from** field to identify the third occurrence.

Note: If the specified substring is not found, then the output will return as **0**.

7. In the **Assign the output to variable** list, specify the number variable.
8. Click **Save**.

Length action

The **Length** action in the String package enables you to retrieve the string length.

Settings

- In the **Source string** field, specify the source string.
- In the **Assign the output to variable** list, specify the number variable.

Lowercase action

The **Lowercase** action in the String package enables you to convert the source string to lowercase.

Settings

- In the **Source string** field, specify the source string.
- In the **Assign the output to variable** list, specify the variable.

Generate random string action

The **Generate random string** action in the String package enables you to generate a string of uppercase and lowercase alphanumeric characters and assign it to a string variable.

Settings

- In the **String length** field, enter the number of characters in the generated string.

Note: The maximum number of characters is 300.

- In the **Enter the destination variable to assign the random string** field, specify the string variable.

Using Replace action

Use the **Replace** action to find a piece of text from the source string and replace it with another text.

A regular expression is a sequence of characters that define a search pattern. For example, to find all email addresses in the source string, specify the following as a regular expression: `\b[A-Z0-9._%~]+@[A-Z0-9.-]+\.[A-Z]{2,4}\b`.

Note:

- The **Replace** action might not replace the Carriage Return and Line Feed (CRLF) characters in a string when you use the Enter variable. To ensure that the characters are replaced, instead of the Enter variable, use the Newline variable.
 - When you use the \$ character in your regular expression pattern, the regular expression field might show an error as \$ is considered as the start of a variable specification. Hence, we recommend you use \$\$ instead.
-

To replace text from the specified string, follow these steps:

1. In the **Actions** palette, double-click or drag the **Replace** action from the **String** package.
 2. In the **Source string** field, specify the source string.
 3. In the **Find string** field, specify the substring.
 4. In the **When finding** field, select one of the options:
 - **Match case**: Matches the case of the text.
 - **Do not match case**: Does not match the case of the text.
 5. In the **The "find string" is** field, select one of the options:
 - **A regular expression**: The substring is a regular expression
 - **Not a regular expression**: The substring is not a regular expression.
 6. Optional: In the **Start from** field, specify the starting position.
The action then starts from the value you specify in this field. For example, if you specify 5 in the **Start from** field for the source string "Big blue ocean", when the bot runs, the action ignores the four preceding characters ("Big", including the space character) and searches for the substring in "blue ocean".
 7. Optional: In the **Count** field, specify the number of times the found string must be replaced.
For example, in the source string "Big blue ocean, blue fish, blue sky", you want to replace the first two instances of "blue" with "green". Enter 2 in the **Count** field, 5 in the **Start from** field, and green in the **Replace with** field. When the bot runs, the action produces the output green ocean, green fish, blue sky.
-

Note: By default, the value in the **Count** field is set to -1, which means that all the instances of the found string will be replaced.

8. In the **Replace with** field, specify the text to replace the string.
9. In the **Assign the output to variable** list, specify the variable that will hold the new string.
10. Click **Save**.

Reverse action

The **Reverse** action in the String package enables you to reverse the source string.

Settings

- In the **Source string** field, specify the source string.
- In the **Assign the output to variable** list, specify the variable.

Using Split action

Use the **Split** action to split the specified string into multiple strings and store the output in a list variable.

To split a string into multiple strings, perform these steps:

1. In the **Actions** palette, double-click or drag the **Split** action from the **String** package.
2. In the **Source string** field, specify the source string.
3. In the **Delimiter** field, specify the character to split the string.
For example, comma (,), semicolon (;), pipe (|), slash (/ \), newline character (\n), or space.
In the delimiter text box, the newline character is not accepted for the Enter key as a line break. In that case, you can either press **F2** and select **Enter - String** from String section or input the `$String:Enter$` variable.
4. In the **Delimiter is** field, select one of the options:
 - **Case sensitive**: The delimiter is case-sensitive.
 - **Not case sensitive**: The delimiter is not case-sensitive.
5. In the **Split into substrings** field, select one of the options:
 - **All possible**: Splits the source string into as many substrings as possible.
For example, if the original string is a,b,c,d, each character becomes a substring.
 - **Only**: Limits the number of substrings.
For example, if the original string is a,b,c,d, and you enter 3, the output is three strings: a, b, and c,d.
6. In the **Assign the output to list variable** field, specify the list variable.
7. Click **Save**.

Example of using Split action

In this example, you will build a bot to read a CSV file, split a specified string into multiple strings.

Prerequisites

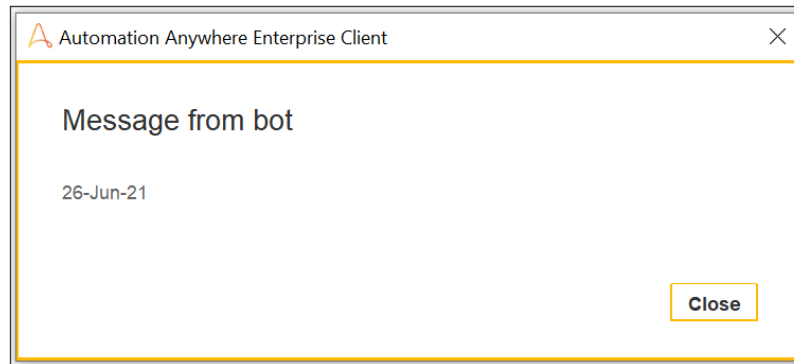

Before you start building the bot, create a file in .CSV format using the data in the following table and save it as **String_datatable.csv**

Name	Location	Joining date
Savio	Bangalore	26-Jun-21
Rene	Bangalore	15-Oct-21

Procedure

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name: `String_split`.
 - d) Click **Create and Edit**.
2. Open and read data from the CSV file.
 - a) Double-click or drag the **Excel advanced > Open** action.
 - b) From the **File** option, in the **Desktop file** field, click **Browse** to select your file.
 - c) Select the **Sheet contains a header** checkbox.
 - d) Open the file in **Read-write** mode.
 - e) In the **Create Excel session** field, select **Local session**.
 - f) Double-click or drag the **Excel advanced > Read row** action.
 - g) From the **Cell option** tab, select **From specific cell** and enter C2 in the **Cell address** field.
 - h) From the **Read option** tab, select **Read visible text in cell** option.
 - i) In the **Session name** field, enter the session that you used to open the file.
 - j) In the **Assign value to the variable** field, click the **Create variable** icon to create a variable.
 - k) On the **Create variable** window, enter `list_outputdata` in the **Name** field.
 - l) Click **Create and select**.
 - m) Double-click or drag the **Excel advanced > Close** action to close the .txt file.
 - n) In the **Session name** field, enter the session name that you used in the **Open** action to open the file.
3. To print the values of the specified row, double-click or drag the **Message box** action. In the **Enter the message to display** field, enter `$list_outputdata[0]$`.

When you run the bot, the bot displays the string in row C2 as **26-**

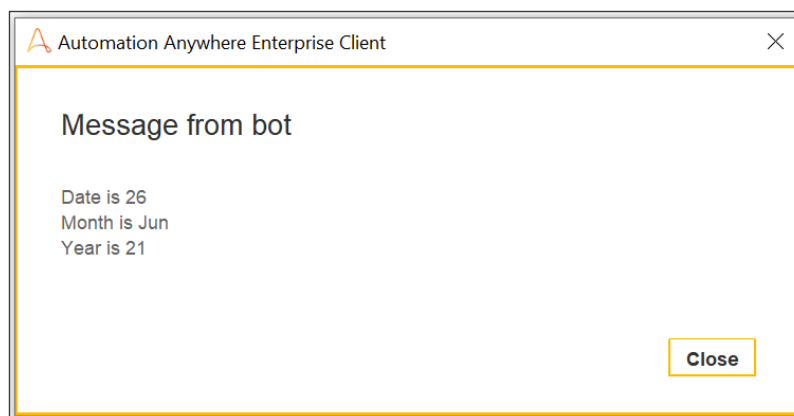

Jun-21.

4. To split the specified string into multiple strings, double-click or drag the **String > Split** action.
 - a) In the **Source string** field, enter `$list_outputdata[0]$`
 - b) In the **Delimiter** field, enter `-`.
 - c) From the **Delimiter is** tab, select **Not case sensitive**.
 - d) From the **Split into substrings** tab, select **All possible**
 - e) In the **Assign value to the variable** field, click the **Create variable** icon to create a variable.
 - f) On the **Create variable** window, enter `substrings_split` in the **Name** field.
 - g) Click **Create and select**.

5. To print the values, double-click or drag the **Message box** action. In the **Enter the message to display** field, enter the following data:

```
Date is $substrings_split[0]$  
Month is $substrings_split[1]$  
Year is $substrings_split[2]$
```
6. Click **Save** and then **Run**.

The bot splits the specified string into multiple substrings and displays the output as follows:

Substring action

The **Substring** action in the String package enables you to extract a substring from a string.

Settings

- In the **Source string** field, specify the source string.
- In the **Start from** field, specify the starting point.
- In the **Length** field, specify the length.
- Select the **Return blank if the range is not found** option to have the output to show a blank value when the value in the **Start from** index field is greater than the source string.
- In the **Assign the output to variable** list, specify the variable.

Example

Before you start building a bot, create a file in .txt format and save it as `extract_substring.txt` in the `C:\Bot testing` folder. Open the `extract_substring.txt` file and enter the text: `Welcome to the Automation 360 platform` and save it.

Create a sample bot and perform the following steps to extract a substring from a source string:

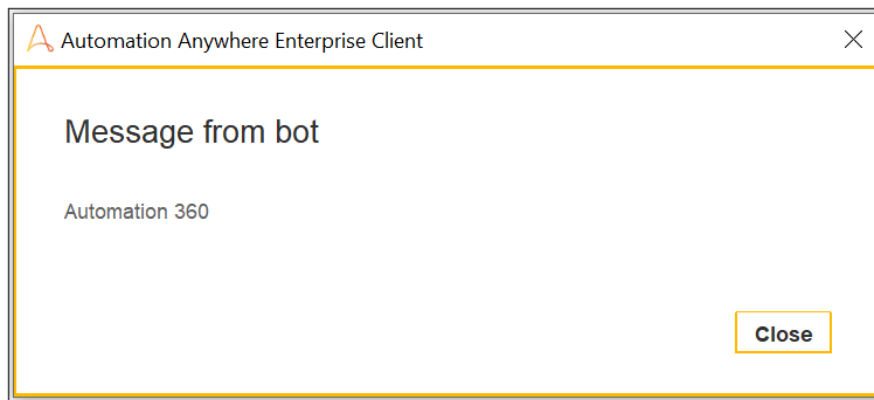

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name: `String_assign`.
 - d) Click **Create and Edit**.
2. Open and read data from the .txt file.
 - a) Double-click or drag the **CSV/TXT > Open** action.

Note: The session name will be set to default.

 - b) In the **File path** field, select the **Desktop file** option and click **Browse** to select your file.
 - c) In the **Delimiter** tab, select the **Comma** check box.
 - d) Double-click or drag the **CSV/TXT > Read** action.
 - e) In the **Assign value to the variable** field, click the **Create variable** icon to create a variable.
 - f) On the **Create variable** window, enter `table_data` in the **Name** field.
 - g) Click **Create and select**.
 - h) Double-click or drag the **CSV/TXT > Close** action to close the .txt file.

- i) In the **Session name** field, enter the session name that you used in the **Open** action to open the file.
3. To extract a substring from the source string, double-click or drag the **String > Substring** action.
 - a) In the **Source string** field, select `$table_data[0][0]`.
 - b) In the **Start from** field, enter 16.
 - c) In the **Length** field, enter 14.
 - d) In the **Assign the output to variable** field, click the **Create variable** icon to create a variable.
 - e) On the **Create variable** window, enter `substring_output` in the **Name** field.
 - f) Click **Create and select**.
4. To print the values, double-click or drag the **Message box** action. In the **Enter the message to display** field, enter `$substring_output`.
5. Click **Save** and then **Run**.

The bot extracts the specific substring from the source string and displays the output as **Automation 360**.

To boolean action

The **To boolean** action in the String package enables you to convert a string to a Boolean.

Settings

- In the **Select string variable** variable field, specify the source string variable.
- In the **Select the boolean variable to store the result** field, specify the Boolean variable.

To locale number action

The **To locale number** action in the String package enables you to convert a string to a locale-formatted number.

Settings

- In the **Source value** field, specify the source string.
- Select any of the following tab to specify locale:
 - **Specify**: Manually specify the two letter ISO codes for the locale you want to use in the **Locale** field.
 - **Device**: Use the default locale configured for the device.
- In the **Save the outcome to a variable** list, specify the variable.

You can also use the action in an expression. For example, `$prompt-assignment.String:toLocaleNumber("en-US")$`.

Example

Create a sample bot and perform the following steps to convert a string to a locale-formatted number:

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name: `String_localenumber`.
 - d) Click **Create and Edit**.
2. To convert a string to a locale-formatted number, from the **Actions** pane, double-click or drag the **String > To locale number** action.
 - a) In the **Source value** field, enter `1,23,345.67`
 - b) Select the **Specify** option and enter `en-US` in the **Locale** field.
 - c) In the **Save the outcome to a variable** field, click the **Create variable** icon to create a variable.
 - d) On the **Create variable** window, enter `Num_output` in the **Name** field.
3. To convert the number to a string, from the **Actions** pane, double-click or drag the **Number > To string** action.
 - a) In the **Enter a number** field, select `Num_output` variable.
 - b) In the **Enter number of digits after decimal (number format)** field, enter `2`.
 - c) In the **Assign the output to variable** field, click the **Create variable** icon to create a variable.

- d) On the **Create variable** window, enter `locale_output` in the **Name** field.
 - e) Click **Create and select**.
4. To print the values, double-click or drag the **Message box** action. In the **Enter the message to display** field, enter `(locale_output)`.
 5. Click **Save** and then **Run**.
- The bot now displays the value as **123345.67**

To number action

The **To number** action in the String package enables you to convert a string to a number.

Settings

This action supports positive, negative, and decimal numbers.

Note: If the string contains commas, remove them by using the **Replace** action to replace each comma with an empty string.

- In the **Enter the string** field, specify the source string.
- In the **Assign the output to variable** field, specify the number variable.

Example

Create a bot to convert a string to a decimal number.

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name: `String_to_number`.
 - d) Click **Create and Edit**.

2. To assign the string to a variable, double-click or drag the **String > Assign** action.
 - a) In the **Select the source string variable(s)/value** field, select `5.78`.
 - b) In the **Select the source string variable(s)/ value (optional)** field, click the **Create variable** icon to create a variable.
 - c) On the **Create variable** window, enter `stringtest` in the **Name** field.
 - d) Click **Create and select**.

3. To convert string to a number, double-click or drag the **String > To number** action.
 - a) In the **Enter the string** field, select `$string_test$` variable.
 - b) In the **Assign the output to variable** field, click the **Create variable** icon to create a variable.
 - c) On the **Create variable** window, enter `numtest` in the **Name** field.
 - d) Click **Create and select**.

4. To print the values, double-click or drag the **Message box** action. In the **Enter the message to display** field, enter `$numtest.Number.toString$`.
5. Click **Save** and then **Run**.

You now observe that the bot truncates the values after the decimal points and displays the output as **5**. Hence, you must again convert this number value to a string value to generate an output that would include the value with the decimal point.

6. To convert the number to a string, from the **Actions** pane, double-click or drag the **Number > To string** action.
 - a) In the **Enter a number** field, select `$numtest$` variable.
 - b) In the **Enter number of digits after decimal (number format)** field, enter `3`.
 - c) In the **Assign the output to variable** field, click the **Create variable** icon to create a variable.
 - d) On the **Create variable** window, enter `numtostring_output` in the **Name** field.
 - e) Click **Create and select**.

7. To print the values, double-click or drag the **Message box** action. In the **Enter the message to display** field, enter `$numtostring_output$`.
8. Click **Save** and then **Run**.

The bot now displays the value as **5.78**.

Trim action

The **Trim** action in the String package enables you to trim blanks, whitespaces, tabs, and line breaks from a string.

Settings

- In the **Source string** field, specify the source string.
- In **Trim from the beginning** and **Trim from the end**, select options.
- In the **Assign the output to variable** field, specify the variable.

Uppercase action

The **Uppercase** action in the String package enables you to convert the source string to uppercase.

Settings

- In the **Source string** field, specify the source string.
- In the **Assign the output to variable** list, specify the variable.

Import string from text file action

The **Import string from text file** action in the String package enables you to import values from a variable in a text file into a string variable.

Settings

- Select the text file from the Control Room, desktop, or a file variable.
- In the **Variable key** field, specify the variable that holds the values to import. This field is not case-sensitive.

When a bot runs this action, it retrieves the values between the = sign and line break.

- In the **Assign the output to variable** list, specify the variable.

Note: If you built a bot using this action from the String package from Build 5322 or earlier, the action will be missing when you open the bot with the default package version. You must reinsert the action and repopulate the fields.

System package

Use the actions in the System package to automate locking, logging off, restarting, and shutting down the computer. Use these actions at the end of a task.

The System package includes the following actions:

Note: If you are on Automation 360 v.22 (Build 10526) or a later version, we recommend that you use the Automation 360 v.22 or a later System package version to run your bots seamlessly.

Action	Description
Lock computer	See Lock computer action on page 2977.
Logoff	See Logoff action on page 2977.
Restart	See Restart action on page 2977.
Shutdown	See Shutdown action on page 2977.
Get environment variable	See Get environment variable action on page 2977.

Related tasks

[Using Log text to file action](#) on page 2677

The **Log text to file** action in the Log To File package enables you to create a log file with data about the events that occur when a Task Bot runs.

Related reference

[Application package](#) on page 2326

Use the Open Program/File action in the Application package to launch an application or a file. This action supports .exe, .bat, script files, or shortcut paths.

[System package updates](#) on page 910

Review the updates in released versions of the System package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Lock computer action

The **Lock computer** action enables you to lock the local machine on which the bot is run.

Logoff action

The **Logoff** action enables you to log off from the current user session of the local machine on which the bot is run.

Restart action

The **Restart** action enables you to restart the local machine on which the bot is run.

Shutdown action

The **Shutdown** action enables you to turn off the local machine on which the bot is run .

Get environment variable action

The **Get environment variable** action enables you to get all the environment variables from the specified local machine and assign it to a variable.

Settings

- (Optional) In the **Environment variable list** tab, click the drop-down menu and select one of the variables.

The following table lists the variable details:

Variable	Description	Example value
ALLUSERSPROFILE	Returns the path to the directory that contains resources and settings used by all system accounts. Note: Use ProgramData for devices that run Windows Vista and later OS.	C:\ProgramData
APPDATA	Returns the file path to the application data directory. This directory contains the settings for applications shared across multiple devices.	C:\Users\ \<user> \AppData \Roaming

Variable	Description	Example value
COMPUTERNAME	Returns the device name without the domain.	AA-NY-FRANKSINATRA
CommonProgramFiles	Returns the file path to the Common Files directory.	C:\Program Files\Common Files
CommonProgramFiles(x86)	Returns the file path to the Common Files directory. Note: This is only available for devices that run 64-bit version.	C:\Program Files (x86)\Common Files
CommonProgramW6432	Returns the file path to the Common Files directory. Note: <ul style="list-style-type: none"> This is only available for devices that run 64-bit version. Only use CommonProgramW6432 for devices that run Windows Vista and later OS 	C:\Program Files\Common Files
ComSpec	Returns the file path to the command processor	C:\Windows\system32\cmd.exe
DriverData	Returns the file path to the Driver Data directory.	C:\Windows\System32\Drivers\DriverData
HOMEDRIVE	Returns the home drive of the device.	C:
HOMEPATH	Returns the homedir of the device without the system drive.	\Users\ <user>< td=""> </user><>
LOCALAPPDATA	Returns the file path to the application data directory. This directory contains the settings for applications shared across multiple devices.	C:\Users\ <user>\appdata\local< td=""> </user>\appdata\local<>
LOGONSERVER	Returns the name of the group or domain to which the device is connected	\\SJCSRVBKP
NUMBER_OF_PROCESSORS	Returns the number of processors in the device.	4

Variable	Description	Example value
OneDrive	Returns the path to the OneDrive folder.	C:\Users \<user> \OneDrive
OS	Returns the device operating system name.	Windows_NT
Path	Returns a semicolon-delimited list of directories that contain executable programs.	C:\Windows \system32;C: \Windows;C: \Windows \System32\Wbem;C: \Windows \System32\WindowsPowerShell \v1.0\
PATHEXT	Returns a semicolon-delimited list of file extensions that the system can execute.	.COM;.EXE;.BAT;.CMD;.VBS;.VBE
PROCESSOR_ARCHITECTURE	Returns the process architecture of the device.	AMD64
ProgramData	Returns the path to the directory that contains resources and settings used by all system accounts. Note: Use ALLUSERSPROFILE for devices that run the Windows XP and earlier OS.	C: \ProgramData
ProgramFiles	Returns the path to the directory that stores installed programs.	C:\Program Files
ProgramFiles(x86)	Returns the path to the directory that stores installed programs. Note: This is only available for devices that run 64-bit version.	C:\Program Files (x86)
ProgramW6432	Returns the path to the directory that stores installed programs.	C:\Program Files
PSModulePath	Returns file paths to the modules that are installed on the disk.	%ProgramFiles % \WindowsPowerShell \Modules;C: \Windows \system32\WindowsPowerShell \v1.0\Modules
PUBLIC	Returns the Public folder path.	C:\Users\Public
SystemDrive	Returns the device system drive.	C:

Variable	Description	Example value
SystemRoot	Returns the system root folder.	C:\Windows
TMP	Returns the path to the directory that stores temporary files.	C:\Users\ \<user> \AppData\Local \Temp
TEMP	Returns the path to the directory that stores temporary files.	C:\Users\ \<user> \AppData\Local \Temp
USERDNSDOMAIN	Returns the DNS domain of the user.	AAI.AASPL- BRD.COM
USERDOMAIN	Returns the domain of the user.	AAI.AASPL- BRD.COM
USERDOMAIN_ROAMINGPROFILE	Returns the domain of the user profile.	AAI
USERNAME	Returns the logged-in user name.	bob.ross
USERPROFILE	Returns the user profile path.	C:\Users \<user>
windir	Returns the Windows directory path.	C:\Windows

- (Optional) Use the **Variable** tab to add a value for the variable.
Click **Insert a value** icon if there is no existing variable.
- Click the **Assign the output to an existing variable** drop-down menu and select an existing variable.
Click the **Create variable** icon for new variable.

Task Bot package

Use the **Run**, **Pause**, and **Stop** actions in the Task Bot package to manage running one or more child bots from a parent bot or with a third-party software using an API.

Build smaller bots that automate a single task and run them from a parent bot. For example, build a `Login` child bot to enter the username and password into a web form and click submit. The `Login` child bot accepts credentials from the parent bot and returns a success message, and then the parent bot can call the subsequent `CreateInvoice` child bot. The `Login` child bot should also contain error handling logic in case the credentials are incorrect.

This practice of building smaller, self-contained bots enables a user to reuse the bot logic in a greater number of tasks, and makes error handling and troubleshooting easier. This also decreases the amount of time spent building and maintaining bots. As a result, an organization is able to rapidly scale their automation initiatives. The `Login` child bot from this example can be reused in any task that involves providing credentials to a login page on a website.

When you run a Task Bot that calls itself repeatedly until you choose to stop it, the bot runs infinitely and, as a result, encounters an error related to stack memory issues. We recommend that you create a parent and a child bot with different names and then run the child bot from the parent bot.

Note:

- CSV/text file and Recorder sessions cannot be shared across bots. You can share Excel sessions across bots by using a session variable. See [Example for sharing an Excel session between bots](#) on page 2985.
- When you use a file type variable in the Run Task, ensure you have set the default value in the variable. Without default value, the bot displays an error on execution.

In addition, running child bots from a parent bot offers greater control over data in the following ways:

- Users can configure the variables in the child bot to control the direction in which information can be exchanged by selecting from the following options:
 - **Use as input:** The variable holds a value that the child bot accepts from a parent bot or third-party software.
 - **Use as output:** The variable holds a value that the child bot passes to the parent bot or third-party software.
 - **Both:** The value can be passed in both directions.
 - **Neither:** The variable is confined to this bot; it cannot be shared across other bots.

See [Create a variable](#) on page 2246

- Other users can reuse child bots without viewing their contents.

The Task Bot package includes the following actions:

Action	Description
Pause	See Pause action on page 2982.
Run	<ul style="list-style-type: none"> • See Using the Run action on page 2982.. • For an example, see Example of using the Run action on page 3095.
Stop	See Stop action on page 2985.

Related reference

[Task Bot package updates](#) on page 911

Review the updates in released versions of the Task Bot package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Pause action

The **Pause** action in the Task Bot package enables you to temporarily pause the running bot.

Settings

Temporarily pauses the running bot. Use the **Pause** action to modify data or to verify the status of a relevant component.

When the bot reaches the **Pause** action during run time, a **Resume** button appears. You must click **Resume** for the bot to continue to the next action.

Using the Run action

The **Run** action from the Task Bot package enables you to run one or more child bots. Configure the action to run the child bots repeatedly or with a delay, and to pass and retrieve values.

The action runs the selected task multiple times for a specified number of times or for a number of hours. The task can be repeated until the user chooses to stop it. You can save the output values to a dictionary variable, where each key in the dictionary is the variable name and corresponding value from the child bot. Or, you can map each dictionary key to a variable to store the corresponding value.

Note: When you create a Task Bot with dependencies, ensure that the both the parent and child bot are in the same workspace (public or private). You cannot call a public bot from a private bot. To do so, you should first either check-out or clone the public bot into the private workspace and then check-in both the bots to the public workspace.

1. In the **Actions** palette, double-click or drag the **Run** action from the **Task Bot** package.
2. In the **Task Bot to run** field, select the child bot:

Option	Description
Current Task Bot	Runs the current bot recursively.

Option	Description
Control Room file	<p>Select a bot that you want to run:</p> <ul style="list-style-type: none"> Click the Browse tab if you want to select a bot from your private workspace. <p>The location of the selected bot in the private repository is also displayed.</p> <ul style="list-style-type: none"> Click the Search tab if you want to search for a bot from the public workspace and your private workspace. <p>Suggestions about the bots available in the public and private workspaces are displayed when you start typing the name of the bot you want to run. The location of the selected bot in the public and the private workspaces is also displayed.</p>
Variable	<p>Select from the following options:</p> <ul style="list-style-type: none"> File: Insert a file variable that contains a bot. Control Room path: Enter an expression beginning with <code>Bots</code> that contains a string variable to specify the bot. For example <code>Bots/\$department\$/PTOReport</code>. <hr/> <p>Note:</p> <ul style="list-style-type: none"> The file path is case-sensitive. The bot must be in the same workspace as the parent bot. <hr/>

3. In the **Input values** fields, enter the values or variables to pass to the child bot:

Note: You can pass a Window type variable from a parent bot to a child bot.

- a) Select an input variable to activate the text field.
- b) Enter a value of the required data type.
The icon on the left-side of the text field indicates the data type.

If you are configuring a bot with many input variables, use the **Quick map** option to automatically map variables that share the same name and data type. If the child bot contains variables for which there are no corresponding variables in the parent bot, the **Quick map** option creates new variables and maps them.

4. Optional: Select the repetition.
See [Repeating a bot](#) on page 2985.
5. Optional: Select the **Delay between repetitions** option and enter the delay time in the **Minutes** and **Seconds** fields.

6. Optional: Select the **Upon error continue with next repetition or action in this bot** option. For alternative error-handling options, use actions from the Error handler package.

[Error handler package](#) on page 2466

7. In the **Save outcome to a variable** field, select either the **Multiple variables** or **Dictionary** option:

Option	Description
Multiple variables	<p>Click Add variable mapping to associate each dictionary key with a variable in the parent bot.</p> <p>Use this option if you do not want to use actions to extract the dictionary values.</p> <p>Use the Multiple Variables option to assign the output of the child bot to multiple variables directly. Using this option, you can set the multiple values returned by the child bot into the dictionary variable of the parent bot. You no longer need to assign the multiple outputs of the child bot to the individual variables of the parent bot using variable assignment commands. You can use the Dictionary package in the parent bot to extract the individual value assigned to the dictionary variable of the parent bot.</p> <p>For example, when you migrate Enterprise 11 bots, many output variables need to be assigned individually after the Run task action, which increases the size of the bot. You can directly set parent bot variables within the Run task action using the multiple variables option.</p>
Dictionary	<p>Insert or create a dictionary variable to hold the output variables and values in key-value pairs.</p> <p>Each key in the dictionary is the variable name and corresponding value from the child bot.</p>

8. Click **Save**.

For an example of using this action:

- [Example of using the Run action](#) on page 3095
- [Example for sharing an Excel session between bots](#) on page 2985

Repeating a bot

Use the repeat option in the **Run** action of the Task Bot package to enable the repeat setting in a bot. You can use this option to repeat a bot after a run failure or to run routine bots.

Options for repeating a bot

Do not repeat	Default. The bot runs once.
Repeat N times	Repeats the bot specified number of times.
Repeat for time unit	Repeats the bot for a time period (hh:mm:ss).
<hr/>	
	Note: Specify up to 99 hours, 59 minutes, or 59 seconds.
<hr/>	
Repeat until stopped by user	Repeats the bot until being stopped manually by clicking the stop button or by pressing the ESC key.
Delay between repetitions	Sets a duration of time to wait before repeating a bot (mm:ss).
Upon error continue with next repetition or action in this bot	The bot is repeated regardless of run failure.
<hr/>	
	Note: Error handling cannot capture the error when this option is enabled.
<hr/>	

Stop action

The **Stop** action in the Task Bot package enables you to stop the running bot.

Settings

For example, use the **Stop** action to terminate the bot if a condition is met, such as if the bot encounters a file larger than 100 MB.

Example for sharing an Excel session between bots

Build two bots to update the employee salaries in a worksheet. In this example, one bot opens an Excel worksheet and passes the session name as a variable to the second bot, which iterates through the worksheet, calculates each employee's new salary, and updates the value in the worksheet.

Create a worksheet with the following data:

Employee ID	Start date	Salary
200	1/12/2020	50000
233	3/15/2018	75000

Employee ID	Start date	Salary
500	6/6/2020	60000
555	7/9/2019	65000

Build the child to iterate through the table of employees and update each salary to reflect the raise.

1. Open a new bot.
 - a) From Automation Anywhere web interface, on the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name `RaiseSalaries`.
 - d) Enter the folder location `\Bots\TaskBotExample`.
To change where your bot is stored, click **Choose** and follow the prompts.
 - e) Click **Create and Edit**.

2. Create the following variables:
 - `sessionVariable`: session type; MS Excel subtype; use as input
 - `sCellAddress`: string type; default value of `C2`
 - `sSalary`: string type
 - `nSalary`: number type

3. Use a **Loop** action to iterate through all the rows in the worksheet.
 - a) Double-click or drag the **Loop** action.
 - b) Select the **For each row in worksheet** iterator.
 - c) Select the **Shared session** tab and insert `$sessionVariable$`.
 - d) Select the **Read cell value** option.
 - e) In the **Assign the current value to this variable** field, create a record variable.

4. Retrieve the employee's salary.
 - a) Drag into the Loop container the **Excel Advanced > Get single cell** action.
 - b) Select the **Shared session** tab and insert `$sessionVariable$`.
 - c) Select the **Specific cell** option and insert `$sCellAddress$`.
 - d) Select the **Read cell value** option.
 - e) In the **Store cell contents to** field, insert `$sSalary$`.

5. Convert the salary value to a number data type.
 - a) Drag into the Loop container the **String > To number** action.
 - b) In the **Enter the string** field, insert `$sSalary$`.
 - c) In the **Assign the output to variable** field, insert `$nSalary$`.

6. Calculate the new salary to be five percent greater than the current salary.

- a) Drag into the Loop container the **Number > Assign** action.
 - b) In the **Select source variable** field, enter `$nSalary$*1.05`.
 - c) In the **Select destination variable** field, insert `$nSalary$`.
7. Update the salary in the worksheet.
- a) Drag into the Loop container the **Excel Advanced > Set cell** action.
 - b) Select the **Shared session** tab and insert `$sessionVariable$`.
 - c) Select the **Specific cell** option and insert `$sCellAddress$`.
 - d) In the **Cell value** field enter `$nSalary.Number.toString$`.

Note: You must convert the value to a string data type before the bot can enter it into the worksheet. Use type casting as an alternative to the **Number > To string** action. [Type conversion](#) on page 2248

8. Move the cursor down by a single cell and assign that cell address to `sCellAddress`.
- a) Drag into the Loop container the **Excel Advanced > Go to cell** action.
 - b) Select the **Shared session** tab and insert `$sessionVariable$`.
 - c) Select the **Active cell** and **One cell below** options.
 - d) Drag into the Loop container the **Excel Advanced > Get cell address** action.
 - e) Select the **Shared session** tab and insert `$sessionVariable$`.
 - f) Select the **Active cell** option.
 - g) In the **Save active cell address** field, insert `$sCellAddress$`.

9. Click **Save** and **Close**.

Build the parent bot.

10. Open a new bot.
- a) Click **Create a bot**.
 - b) Enter the bot name `ExcelParentBot`.
 - c) Enter the folder location `\Bots\TaskBotExample`.
To change where your bot is stored, click **Choose** and follow the prompts.
 - d) Click **Create and Edit**.

11. Create the following variable:

`sessionVariable`: session type; MS Excel subtype

12. Double-click or drag the **Excel Advanced > Open** action.
13. Within the **File > Desktop file** tab, click **Browse** to upload a file:
14. Select the **Sheet contains header** check box.
15. In the **Create Excel session** field, click **Global session** tab and use the **Insert a value** icon to select `sessionVariable`.
16. Select the child bot that you have created.
- a) Double-click or drag the **Task Bot > Run** action.
 - b) In the **Control Room file** tab, click **Choose** to select the `RaiseSalaries` bot.

- c) In the **Input values** section, select the **Global session** option and insert `$sessionVariable$`.

17. Click Save and Run.

The Excel worksheet opens and the value of each cell in the third column increases by five percent.

Terminal Emulator package

The **Terminal Emulator** package contains actions that enable you to connect to and automate tasks on another machine. Use these actions to access and control operations on a remote machine. For example, you can run applications and access files on a different operating system.

The Terminal Emulator enables a machine to connect to and communicate with another machine using a command-line or graphical interface. The Terminal Emulator uses the Telnet or SSH protocol to communicate with other machines.

The Terminal Emulator supports ANSI, TN3270E, TN5250E, and VT100 terminal types.

Important: If you use different versions of the Terminal Emulator package in a parent bot and a child bot, the capability to share a session across bots is currently not supported. To share a session across parent and child bots, ensure that you use the same version of the package in both the parent and child bots.

Before you start

Important: Before you establish a connection to a different terminal type, ensure that you have Visual C++ 2019 Redistributable Package installed on your system. If you are on an Automation 360 version earlier than A2019.14 (Build 5322), you must install Visual C++ 2013 Redistributable Package or Visual C++ 2015 Redistributable Package on your system.

Perform the following actions within the **Terminal Emulator** package as part of using the set of available actions:

1. Establish a connection with a host machine using the **Connect** action.

You must first establish a connection with a host machine to automate any Terminal Emulator related task. When establishing the connection, specify the details of the host machine and associate it with a session name. Use the session name provided in this action in the other actions so that you do not have to provide details of the host machine in those actions again. See [Using Connect action for Terminal Emulator](#) on page 2990.

Important: If you use any other action from this package before establishing the connection, you will encounter an error.

2. Use the Terminal Emulator actions to automate a task. For example, use the **Get field** action to retrieve the value from a particular field.
3. After you have automated all the Terminal Emulator related tasks, terminate the connection to the host machine using the **Disconnect** action.

Actions in the Terminal Emulator package

The **Terminal Emulator** package includes the following actions:

Action	Description
Clear terminal	Clear terminal action on page 2990
Connect	Using Connect action for Terminal Emulator on page 2990
Disconnect	Disconnect action on page 2995
Get all fields	Get all fields action on page 2995
Get field	Get field action on page 2996
Get text	Using Get text action for Terminal Emulator on page 2996
Hide terminal	Hide terminal action on page 2997
Search field	Search field action on page 2997
Send key	Using Send key action on page 2997
Send text	Using Send text action on page 3000
Set key mappings	Using Set key mappings on page 3001
Set cursor position	Set cursor position action on page 3002
Set field	Using Set field action on page 3002
Set session variable	Set session variable action on page 3003
Show terminal	Show terminal action on page 3003
Wait	Using Wait action on page 3003

Related reference

[Terminal Emulator package updates](#) on page 913

Review the updates in released versions of the Terminal Emulator package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Clear terminal action

The Clear terminal action in the Terminal Emulator package enables you to clear the screen of the terminal.

Settings

Specify the **Terminal emulator session name** that you used to establish a connection with the terminal using the **Connect** action.

Using Connect action for Terminal Emulator

Use the **Connect** action to establish a connection with a host machine on which you want to automate a task. You can use this action to establish a connection with the TN3270E, TN5250E, ANSI, VT220, and VT100 terminal types.

This action enables you to specify the details of the host machine and associate it with a session name. Use the session name provided in this action in the other actions, so that you do not have to provide details of the host machine in those actions again.

Important: If you use any other action from this package before establishing the connection, you will encounter an error.

To establish a connection with a host machine, perform the following steps:

1. Double-click or drag the **Connect** action from the **Terminal Emulator** node in the **Actions** palette.
2. Specify a name for the session in the **Terminal emulator session name** field.

Note: Use the different session name to open multiple terminal windows. If you want to use the same session name, you must first close the session of the first terminal window before using the same session name for another terminal window.

3. Specify the **Host name** of the machine you want to connect to:
 - a) Click the **Credential** tab to select an entry from the Credential Vault.
 - b) Click the **Variable** tab to use a variable to specify the host name.
4. Enter a value in the **Port** field to specify the port you want to use to connect to the host.
5. Select one of the following options to specify the terminal type:

Option	Steps
ANSI	<p>Select an option from the Connection type list to specify the type of connection you want to establish:</p> <ul style="list-style-type: none">• Telnet• SSH2 <p>For SSH2 connection type:</p> <ul style="list-style-type: none">• For User authentication:<ul style="list-style-type: none">• User name: Click the Credential tab to select an entry from the Credential Vault. You can also click the String tab to enter a value manually.• For Password: Click the Credential tab to select an entry from the Credential Vault. You can also click the String tab to enter a value manually.• For Key file authentication: Click one of the following options to specify the location of the file:<ul style="list-style-type: none">• Control Room file: Enables you to select a PDF file that is available in a folder.• Desktop profile: Enables you to select a PDF file that is available on your device.• Variable: Enables you to specify the file variable that contains the location of the PDF file.• For User name: Click the Credential tab to select an entry from the Credential Vault. You can also click the String tab to enter a value manually.

Option	Steps
TN3270E	<p>a) Select an option from the Host name security list to specify the security you want to use:</p> <ul style="list-style-type: none"> • NONE • SSL • TLS <p>b) Select the Enable TN3270E support check box if you want to choose a connection method.</p> <p>Select an option from the Connection method list:</p> <ul style="list-style-type: none"> • GENERIC: Enables you to specify the Device name. • SPECIFIC: Enables you to specify the Device name and Resource (LU) Name. <p>c) Select an option from the Terminal model list to specify the terminal workstation you want to connect to.</p> <p>d) Select the check box to enable extended attributes on the TN3270E terminal.</p> <p>e) Select an option from the Code page list to specify the encoding you want to use for the terminal.</p>
TN5250E	<p>a) Select an option from the Host name security list to specify the security you want to use:</p> <ul style="list-style-type: none"> • NONE • SSL • TLS <p>b) Select the Enable TN5250E support check box if you want to specify details about the device and resource.</p> <p>Enter a value in the Device name and Resource (LU) Name fields.</p> <p>c) Select an option from the Terminal model list to specify the terminal workstation you want to connect to.</p> <p>d) Select an option from the Code page list to specify the encoding you want to use for the terminal.</p>

You can also click the String tab to enter a value manually. <p>d) To determine the device attribute response that the terminal sends on request from the host, select the Custom DA string check box and enter the DA (Device Attributes) response of type string.</p>

Option	Steps
Linux	<p>Select an option from the Connection type list to specify the type of connection you want to establish:</p> <ul style="list-style-type: none"> • Telnet • SSH2 <p>For SSH2 connection type:</p> <ul style="list-style-type: none"> • For User authentication: <ul style="list-style-type: none"> • User name: Click the Credential tab to select an entry from the Credential Vault. You can also click the String tab to enter a value manually. • For Password: Click the Credential tab to select an entry from the Credential Vault. You can also click the String tab to enter a value manually. • For Key file authentication: Click one of the following options to specify the location of the file: <ul style="list-style-type: none"> • Control Room file: Enables you to select a PDF file that is available in a folder. • Desktop profile: Enables you to select a PDF file that is available on your device. • Variable: Enables you to specify the file variable that contains the location of the PDF file. • For User name: Click the Credential tab to select an entry from the Credential Vault. You can also click the String tab to enter a value manually.

Note: When you connect with the SSH2 server using public key authentication, the SSH client uses the private key file associated with the public key that has been authorized on the server.

Depending on the software used to generate SSH2 private keys, you can store SSH2 private keys using any of the file formats:

- Java KeyStore (JKS) format: Used by Java applications to store private keys, certificates, and other cryptographic data. The private key is stored in a file with a `.jks` extension.
- OpenSSH format(default format): Used by the OpenSSH suite of tools, including the `ssh-keygen` utility. The private key is stored in a file with no extension, typically named `id_rsa`, `id_dsa`, or `id_ecdsa` (based on the key type).
- OpenSSL format: Used by the OpenSSL library and other software that uses OpenSSL, such as Apache and NGINX. The private key is stored in a file with a `.pem` or `.key` extension.
- PKCS8 key format: Used as a standard format for securely storing private keys using the PKCS#8 standard. The private key is stored in a file with a `.pem` or `.key` extension.
- PuTTY format: Used by the PuTTY SSH client for Windows. The private key is stored in a file with a `.ppk` extension.

6. Select the **Show terminal window** check box to show the terminal window when the bot runs this action.

7. Select the **Set cursor position to the beginning** check box to edit the screen of the Terminal emulator session manually and set the focus to the first editable field.
8. Select the **Wait for the terminal prompt to appear while connected** check box to wait for the terminal prompt to appear on the screen of the terminal after the connection is established.
 - a) Enter the text you want to display when you connect to the terminal in the **Terminal prompt** field.
 - b) Enter a value in the **Wait time out** field to specify the period in (milliseconds) the system must wait before the connection request is timed out.
9. Select any of the following tabs to create a terminal emulator session:
 - **Local session**: Specify a session name that can be used only in the current bot.
 - **Global session**: Specify a session name that can be used across multiple bots such as parent bots, child bots, and other child bots of the parent bots.
 - **Variable**: Specify a session variable that can be used to share that session with other child bots.

Disconnect action

The Disconnect action in the Terminal Emulator package enables you to terminate the connection with the terminal.

Settings

Specify the **Terminal emulator session name** that you used to establish a connection with the terminal using the **Connect** .

Get all fields action

The Get all fields action in the Terminal Emulator package enables you to retrieve the values of all fields and assigns them to a table variable.

Settings

- Specify the **Terminal emulator session name** that you used to establish a connection with the terminal using the **Connect** .
- Select a table variable to store the retrieved data from the **Assign the value to an existing table variable** list. The table stores each field as a row, with the values of each field organized in the following columns:
 - Field index
 - Field name
 - Field value
 - Is Editable (yes/no)
 - Is Hidden (yes/no)

Note: You can use this action with the TN3270E and TN5250E terminal types.

Get field action

The Get field action in the Terminal Emulator package enables you to retrieve the value of a field based on the index or name of the field and assigns it to a string variable.

Settings

- Specify the **Terminal emulator session name** that you used to establish a connection with the terminal using the **Connect** .
- Select the **By index** option to retrieve the value of a field based on its index, or select the **By name** option to retrieve the value of a field based on its name.
- Select a string variable to store the retrieved data from the **Assign the value to an existing variable** list.

Note: You can use this action with the TN3270E and TN5250E terminal types.

Using Get text action for Terminal Emulator

Use the **Get text** action to retrieve text from the terminal and store it in a string variable. This action enables you to retrieve text from the last line, all lines, or a range of lines. You can use this action with the TN3270E, TN5250E, ANSI, and VT100 terminal types.

To retrieve text from the terminal, do the following:

1. Double-click or drag the **Get text** action from the **Terminal Emulator** node in the **Actions** palette.
2. Enter the name of the session that you have used to establish a connection with the terminal using the **Connect** action in the **Terminal emulator session name** field.
3. Select an option from the **Get text** list to specify the lines from which you want to retrieve text:
 - **Last line:** Retrieves text from the last line of the terminal.
 - **All lines:** Retrieves text from all lines of the terminal.

Select from the following options to extract text from a specific area, viewable area, or the entire page displayed on the screen.

- **Viewport:** Retrieves text from the visible area of the Terminal Emulator window.
- **Number of lines from top:** To retrieve text corresponding to a specific number of lines from the top of the screen.
- **Full page capture (with scroll):** Retrieves all the lines on the screen, including the content that needs to be scrolled to access it.

Note: The **Full page capture (with scroll)** and **Number of lines from the top** options are supported only for **ANSI** and **VT Series** terminals. If you connect with other terminal types, regardless of the option selected, the extracted text displays the results similar to how they are displayed for the **Viewport** option.

- **Lines from-to:** Retrieves text from the specified range of lines of the terminal. You must enter values in the **Start row** and **End row** fields to specify the range.

Note: You can specify a value of 1 through 999.

4. Select a string variable from the **Assign the value to an existing variable** list to assign the retrieved text to that variable.
5. In the **Assign value to variable** list, select a string variable.

Hide terminal action

The Hide terminal action in the Terminal Emulator package enables you to hide the terminal screen.

Settings

This action enables you to hide the terminal screen when the **Show terminal window** option from the **Connect** action is selected. It is useful when you do not want to display the terminal screen when a bot is performing certain tasks. Specify the **Terminal emulator session name** that you used to establish a connection with the terminal using the **Connect**.

Search field action

The search field action in the Terminal Emulator package enables you to search for the field based on the text it contains.

Settings

- From the **Terminal emulator session name** field, choose one of the following options:
 - **Local name** to establish a connection with the terminal using the **Connect** action
 - **Shared session** to share the variable from **Set session variable** or from the parent bot
- Specify the text based on which you want to search the field.
- Select an option from **Select field** to specify whether to retrieve the index or name of the field.
- Assign and save the output to a variable.

Note: The search text you enter must be a complete match and is not case-sensitive.

Using Send key action

Use the **Send key** action to send a key to the terminal. You can use these keys to perform various operations on the terminal. You can use this action with the TN3270E, TN5250E, ANSI, and VT100 terminal types.

To send a key to the terminal, do the following:

1. Double-click or drag the **Send key** action from the **Terminal Emulator** node in the **Actions** palette.

2. Enter the name of the session that you have used to establish a connection with the terminal using the **Connect** action in the **Terminal emulator session name** field.
3. Select an option from the **Select key to be send** list to specify the key you want to send.
4. Enter a value in the **Delay after send key command** field to specify the period the system must wait (in milliseconds) after the selected key is sent.
5. Select the **Wait for text or prompt to appear** check box if you want the system to wait for the prompt or certain text to appear on the terminal.
 - a) Select the **Prompt** option if you want the system to wait till the prompt appears on the terminal.
 - b) Select the **Text** option if you want the system to wait till the specific text appears on the terminal.
You must provide the text you want to appear on the terminal in the **Text value to be appear on screen** field.
 - c) Select the **Wait before send key for prompt or text appear** check box if you want the system to wait for the prompt or the specified text to appear on the terminal before sending the selected key.
 - d) Select the **Wait after send key for prompt or text appear** check box if you want the system to wait for the prompt or the specified text to appear on the terminal after sending the selected key.
 - e) Enter a value in the **Time out for prompt or text to appear** field to specify the period (in seconds) the system must wait before the operation times out.
6. In the **Assign value to variable** list, select a string variable.

How send key works in Send text action

Learn how keys work in the **Send Text** action in the Terminal Emulator.

Note: Behavior of the keys that are marked with the asterisk (*) sign in the following tables is defined by the terminal host. The behavior might vary on different terminals.

The following table shows the behavior of the keys in the terminal types TN3270 and TN5250:

Keys	Behavior
KEY_BACKSPACE	Same behavior as the Backspace key on the keyboard.
KEY_BACKTAB	If the cursor is on the first position of a field, it moves to the previous field. Otherwise, it moves to the start of the current field.
KEY_CLEAR	Clears the entire text on the terminal screen.
KEY_ERASEINPUT	Deletes all the text in the field.
KEY_NEXTFIELD	Moves the cursor to the next field on the terminal screen.
KEY_ENTER	Sends Enter key to the terminal host.
KEY_HOME	Moves the cursor to the first editable field on the screen.

Keys	Behavior
KEY_RESET	The reset key only clears the Keyboard lock, such as releasing the terminal if the terminal screen is not working. The screen text and input field values remain the same.
KEY_LEFT	Moves the cursor to the left by one position.
KEY_RIGHT	Moves the cursor to the right by one position.
KEY_UP	Moves the cursor up by one position.
KEY_DOWN	Moves the cursor down by one position.
KEY_PGLEFT	Nothing happens.
KEY_PGRIGHT	Nothing happens.
KEY_PGUP	Page Up key
KEY_PGDOWN	Page Down key
KEY_TABFORWARD	Performs a tab key action on the terminal screen to move the cursor to the next field.
KEY_PF1 *	Same behavior as F1 key on the keyboard.
KEY_PF2 *	Same behavior as F2 key on the keyboard.
KEY_PF3 *	Same behavior as F3 key on the keyboard.
KEY_PF4 *	Same behavior as F4 key on the keyboard.
KEY_PF5 *	Same behavior as F5 key on the keyboard.
KEY_PF6 *	Same behavior as F6 key on the keyboard.
KEY_PF7 *	Same behavior as F7 key on the keyboard.
KEY_PF8 *	Same behavior as F8 key on the keyboard.
KEY_PF9 *	Same behavior as F9 key on the keyboard.
KEY_PF10 *	Same behavior as F10 key on the keyboard.
KEY_PF11 *	Same behavior as F11 key on the keyboard.
KEY_PF12 *	Same behavior as F12 key on the keyboard
KEY_PF13 *	Same behavior as Shift + F1 keys on the keyboard.
KEY_PF14 *	Same behavior as Shift + F2 keys on the keyboard.
KEY_PF15 *	Same behavior as Shift + F3 keys on the keyboard.
KEY_PF16 *	Same behavior as Shift + F4 keys on the keyboard.
KEY_PF17 *	Same behavior as Shift + F5 keys on the keyboard.
KEY_PF18 *	Same behavior as Shift + F6 keys on the keyboard.
KEY_PF19 *	Same behavior as Shift + F7 keys on the keyboard.
KEY_PF20 *	Same behavior as Shift + F8 keys on the keyboard.
KEY_PF21 *	Same behavior as Shift + F9 keys on the keyboard.

Keys	Behavior
KEY_PF22 *	Same behavior as Shift + F10 keys on the keyboard.
KEY_PF23 *	Same behavior as Shift + F11 keys on the keyboard.
KEY_PF24 *	Same behavior as Shift + F12 keys on the keyboard.

Using Send text action

Use the **Send text** action to send text to the terminal. This action also enables you to send predefined keys after the text to perform various operations in the terminal. You can use this action with the TN3270E, TN5250E, ANSI, and VT100 terminal types.

You can use the following keyboard shortcuts to send a key on the terminal window using Simulate keystroke action:

Note: The keyboard shortcuts are supported in TN3270 and TN5250.

Key entry	Command
Shift + Control + A	Select all
Shift + Control + C	Copy
Shift + Control + X	Cut
Shift + Control + V	Paste

To send a text to the terminal, follow these steps.

1. Double-click or drag the **Send text** action from the **Terminal Emulator** node in the **Actions** palette.
2. Enter the name of the session that you have used to establish a connection with the terminal using the **Connect** action in the **Terminal emulator session name** field.
3. Specify the **Text** you want to send to the terminal:
 - a) Click the **Credential** tab to select an entry from the Credential Vault.
 - b) Click the **Variable** tab to use a variable that contains the text you want to send.
4. Select the **Send a key after sending the above text** check box if you want to send a key after sending the text.
 - a) Select the key you want to send from the list.
 - b) Enter a value in the **Delay after send key command** field to specify the period (in milliseconds) the system must wait after sending the selected key.
5. Select the **Wait for text or prompt to appear** check box if you want the system to wait for the prompt or certain text to appear on the terminal.
 - a) Select the **Prompt** option if you want the system to wait till the prompt appears on the terminal.
 - b) Select the **Text** option if you want the system to wait till the specific text appears on the terminal.

You must provide the text you want to appear on the terminal in the **Text value to be appear on screen** field.

- c) Select the **Wait before send key for prompt or text appear** check box if you want the system to wait for the prompt or the specified text to appear on the terminal before sending the selected key.
- d) Select the **Wait after send key for prompt or text appear** check box if you want the system to wait for the prompt or the specified text to appear on the terminal after sending the selected key.
- e) Enter a value in the **Time out for prompt or text to appear** field to specify the period (in seconds) the system must wait before the operation times out.

6. In the **Assign value to variable** list, select a string variable.

Using Set key mappings

You can use the **Set key mappings** action to overwrite the default mapping of keys to perform various operations on the terminal.

The set key mapping is instrumental to developers as it enables them to map from key lists, especially when keys behave differently on different terminals. For example, you can map `KEY_PAGEUP` to `{Page Up}`, `{Roll Down}`, or `\x1b[5~` based on the terminal host you connected with.

1. Enter the name of the session or select an existing variable that you have used to establish a connection with the terminal using the **Connect** action in the **Terminal emulator session name** field.
2. Select the **Add key mapping** button to set a key and map it to a custom string or macro. The **Add key mapping** window opens:
 - a) Select the key to map from the drop-down list.
 - b) Add the custom string or macro to send it to the terminal.
 - c) Click **Add**.
The custom key value is added. The following table provide examples of custom values set for function keys.

Key	Custom string or macro
F1	{F1} or \x1b[11~
F2	\x1b[12~
F3	\x1b[13~
ENTER	{Return}

Note:

- In the automation, if you have set custom key values and used subsequent actions such as **Send key** or **Send text**, the default values of keys are overridden with the new set of values.

- You can set and use the custom key values in a particular session. If you create a new session and want to use the custom key values, you must set the keys and map them to a custom string or macro.

-
3. Click **Save**.

Set cursor position action

The Set cursor position field action in the Terminal Emulator package enables you to set the position of the cursor on the screen of the terminal.

Settings

- Specify the **Terminal emulator session name** that you used to establish a connection with the terminal using the **Connect** .
- Specify the row number in which to set the cursor in the **Set row** field.
- Specify the column number in which to set the cursor in the **Set column** field.

Note: You can enter a value of 1 through 999 to specify the row and column number where the cursor is set.

Using Set field action

Use the **Set field** action to set a value in a particular field in the terminal. This action also enables you to send predefined keys after the value to perform various operations in the terminal. You can use this action with the TN3270E, TN5250E, ANSI, and VT100 terminal types.

To set a value for a field in the terminal, do the following:

1. Double-click or drag the **Set field** action from the **Terminal Emulator** node in the **Actions** palette.
2. Enter the name of the session that you have used to establish a connection with the terminal using the **Connect** action in the **Terminal emulator session name** field.
3. Specify the field for which you want to set a value:
 - a) Select the **By index** option to specify the field based on its index.
The index value starts from zero and ends at 99999. For example, if you want to set the value for the third field, you must specify 2 in this field.
 - b) Select the **By name** option to specify the location of the field.
For example, if you want to set the value for a field in the fifth column of the third row, you must specify R3C5 in the field.
4. Specify the **Plain text value** you want to set in the specified field:
 - a) Click the **Credential** tab to select an entry from the Credential Vault.
 - b) Click the **Variable** tab to use a variable that contains the text you want to send.
5. Select the **Send enter key after setting field** check box if you want to send the enter key after setting the field.

This option performs the operation similar to pressing the Enter key after setting the value in the field.

6. Select the **Send a key after sending the above text** check box if you want to send a key after sending the text.
 - a) Select the key you want to send from the list.
 - b) Enter a value in the **Delay after send key command** field to specify the period (in milliseconds) the system must wait after sending the selected key.

7. In the **Assign value to variable** list, select a string variable.

Set session variable action

The Set session variable action in the Terminal Emulator package enables you to assign the session name to a variable.

Settings

Pass this session variable from the parent bot to a child bot by entering the variable as an input type variable in the child bot.

Show terminal action

The Show terminal action in the Terminal Emulator package enables you to show the terminal screen.

Settings

This action enables you to show the terminal screen when the **Show terminal window** option from the **Connect** action is not selected. It is useful when you want to display the terminal screen when a bot is performing certain tasks. You must specify Specify the **Terminal emulator session name** that you used to establish a connection with the terminal using the **Connect** .

Using Wait action

Use the **Wait** action to introduce a delay till specific conditions are met in the terminal. You can use this action to wait before executing the next action till the specific text appears on the screen, the cursor moves to the specified location, and so on. You can use this action with the TN3270E, TN5250E, ANSI, and VT100 terminal types.

To wait till specific conditions are met in the terminal, do the following:

1. Double-click or drag the **Wait** action from the **Terminal Emulator** node in the **Actions** palette.
2. Enter the name of the session that you have used to establish a connection with the terminal using the **Connect** action in the **Terminal emulator session name** field.
3. Select an option from the **Terminal event** list to specify a condition the system should wait till it is met.

The following table provides information about the options available in the list and the input required for each option:

Option	Input required
Wait till text appears	Waits until the text you specified in the Text field matches with the last line of the screen in the terminal.
Wait till text disappears	Waits until the text you specified in the Text field does not match or disappears on the last line of the screen in the terminal.
Wait till cursor moves to position	Waits till the cursor moves to the position you have specified in the Move to row and Move to column fields. Note: You can enter a value of 1 through 999 to specify the row and column number where the cursor is set.
Wait till cursor moves out of position	Waits till the cursor moves out of the position you have specified in the Move out of row and Move out of column fields. Note: You can enter a value of 1 through 999 to specify the row and column number where the cursor is set.
Wait till screen gets blank	No input required.
Wait till screen contains text	Waits till the text you have specified in the Text field is available on the screen of the terminal.
Wait till terminal prompt appears	No input required.
Wait till terminal ready state	No input required.

4. Enter a value in the **How long you would like to wait?** field to specify the period (in milliseconds) the system must wait before the operation times out.
5. In the **Assign value to variable** list, select a string variable.

Share session between Task Bot logic

Use the **Shared Session** option in the Terminal Emulator package to pass the exact state of an application to the concurrently occurring Task Bot logic.

Shared session enables you to reuse actions between Task Bots that run concurrently, for example, connecting to the same application.

To use shared session, create a hierarchy of Task Bot logic that are connected by the **Shared Session** option. As a result, large Task Bot logic are trimmed by removing repetitive commands for connecting and disconnecting.

1. Create a parent bot such as TE_Share_Main that connects to an application on the Terminal Emulator.
2. Use the **Set session variable** action in the TE_Share_Main to assign the current session to a variable such as \$te_session\$ of Terminal Emulator session type.
3. Create a child bot such as TE_BMIS to perform any actions such as **Get text** and **Set field**.
4. Add a Run Task action in the TE_Share_Main to call the TE_BMIS.
5. To pass a session variable from the TE_Share_Main to TE_BMIS, select \$te_session\$ as an input value in the **Set SessionVariable**.
6. In the TE_BMIS, use **Shared session** tab and insert \$te_session\$ as a session variable to obtain data or perform task.
7. In the main task, add an action to disconnect from the application.

Text file package

Open a text file, read data from that file, and save the data to a string variable by using the **Text file** package. This package supports text files encoded in Shift-JIS, ANSI, UTF-16LE, UTF-16BE, Win 1521, Unicode, and UTF-8 and can extract content up to 64kb from text files.

Actions in the Text file package

The Text file package includes the following actions:

Action	Description
Get text	See Using Get text action of Text file package on page 3005
Read variables	See Read variables action on page 3006

Related reference

Review the updates in released versions of packages such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using Get text action of Text file package

Extract content from a text file and save that content to a string variable by using the **Get text** action.

To extract text from a text file, perform the following steps:

1. In the **Actions** palette, double-click or drag the **Get text** action from the **Text file** package.
2. In the **Source file** field, select an option to specify the location of the text file:
 - **Control Room file** to open a file from the Control Room.

- **Desktop file** to open a file from the device. This field also accepts the file path input as a string variable or global value.
 - **Variable** to open a file by specifying a file variable.
3. In the **Text encoding** field, select an encoding to specify the encoding that is applied on the text file. Data from the text file will be retrieved based on the selected encoding option even if the input file has a different encoding.
- **ANSI**
 - **UTF8**
 - **UTF8 with BOM**
 - **UNICODE**
 - **Win1251**
 - **UTF-16LE**
 - **UTF-16BE**
 - **Shift-JIS**
 - **Detect automatically**: identifies file encoding. This option supports UTF-8 with BOM, ANSI, UTF-16LE, and UTF-16BE file encoding.
4. Select the **Trim leading spaces** and **Trim trailing spaces** check boxes to remove the leading and trailing spaces from the data extracted from the text file.
5. In **Save the outcome to variable** field, select a string variable to hold the output.

Read variables action

You can use the **Read variables** action in the Text file package to read the values of variables from the text file.

Settings

- In the **Source file** field, select an option to specify the location of the text file:
 - **Control Room file**: Opens a file from the Control Room.
 - **Desktop file**: Opens a file from the device. This field also accepts the file path input as a string variable or global value.
 - **Variable**: Opens a file by specifying a file variable.
- In the **Text encoding** field, specify the encoding to apply on the text file. Data from the text file is retrieved based on the selected encoding option even if the input file has a different encoding.
 - **ANSI**
 - **UTF-8**
 - **UTF-8 with BOM**
 - **Unicode**
 - **Windows 1251**
 - **UTF-16LE**
 - **UTF-16BE**
 - **Shift-JIS**

- **Detect automatically:** Identifies the file encoding. This option supports UTF-8 with BOM, ANSI, UTF-16LE, and UTF-16BE file encoding.
- Select the **Trim leading spaces** and **Trim trailing spaces** check boxes to remove the leading and trailing spaces from the data extracted from the text file.
- Select the **Convert dictionary keys to lower case before assignment to variables** to convert all the keys to lower case.

Note: When you select this option, ensure that you enter the key in lower case in the **Mapped variables** table.

- From the **Save the outcome to variable** field, select one of the following options to contain the output:
 - **Multiple variables:** Click **Add variable mapping** to associate each dictionary key with a variable. Use this option to avoid using actions to extract the dictionary values.
 - **Dictionary:** Insert or create a dictionary variable to contain the output variables and values in key-value pairs.

Trigger loop package

The **Trigger loop** package enables you to run a series of actions when a trigger event occurs. You can insert multiple trigger loops within a bot or nest one trigger loop within another trigger loop.

Actions in the Trigger loop package

Action	Description
Trigger loop	<p>Opens the loop to run a series of actions when a trigger event occurs.</p> <hr/> <p>Note: Events within the Trigger loop follow a sequential order and any parallel events that occur during this time are queued.</p> <hr/>
Handle	<p>Specifies the trigger event and runs the actions that are inside the container when that event occurs.</p> <p>Drag the Handle action into the Trigger loop (in Flow view) or below the Trigger loop (in List view).</p>
Break	<p>Terminates the trigger loop for bot to continue with other actions in the trigger event. If there is no Break action after a trigger loop handle, the bot will go back to the start of the trigger loop and wait for the next configured action. So ensure you add the Break action to exit the trigger loop and move on to next action or else the bot will run indefinitely. For example, the Break action in a bot can be used when the user must close or cancel a form.</p> <p>Drag the Break action into the trigger handle container.</p>

Triggers in the Handle action

Triggers	Description	Options
Email Trigger	Triggers that starts the bot when an email is sent or received.	Using Email Trigger in Trigger loop Handle on page 3009
File Trigger	Triggers on a file event.	Using File Trigger in Trigger loop Handle on page 3012
Folder Trigger	Triggers on a folder event.	Using Folder Trigger in Trigger loop Handle on page 3013
Hot key Trigger	Triggers on a key press event.	Using Hot key Trigger in Trigger loop Handle on page 3013
Form Trigger	<p>Trigger on form element events.</p> <p>Using interactive forms on page 3214</p> <hr/> <p>Note: If an active form is terminated using the Close button from the task bar, it will not terminate the associated bot containing Trigger loop and Interactive forms packages.</p> <hr/>	Using Form Trigger in Trigger loop Handle on page 3014
Object Trigger	<p>Trigger for the bot to start when the Select main event takes place on the trigger interface element. (Users click a button)</p> <hr/> <p>Note: Interface triggers for objects are available only for native Windows applications.</p> <hr/>	Using Object Trigger in Trigger loop Handle on page 3014
Microsoft 365 Outlook Email Trigger	Trigger that starts the bot when an email is received by connecting to the Microsoft 365 Outlook server with OAuth2 authentication.	Using Microsoft 365 Outlook trigger in Trigger loop: Handle on page 3015
Process Trigger	Trigger that starts the bot on a process event.	Use Process Trigger in Trigger loop Handle on page 3016
Service Trigger	Trigger that starts the bot when service start, stop, pause, and resume.	Using Service Trigger in Trigger loop Handle on page 3016
ServiceNow New Record Trigger	New record trigger for ServiceNow .	Using ServiceNow New Record Trigger in Trigger loop Handle on page 3017
ServiceNow Updated Record Trigger	Update record trigger for ServiceNow .	Using ServiceNow Updated Record Trigger in Trigger loop Handle on page 3018

Triggers	Description	Options
Window Trigger	Trigger that starts the bot based on window actions.	Using Window Trigger in Trigger loop Handle on page 3019

Related tasks

[Add a form to bot](#) on page 3231

Adding an existing form to a bot enables users to collaborate with bots. Use the necessary action items to create a bot and build a task logic.

Using Email Trigger in Trigger loop Handle

You can use the email trigger to start the bot when an email is sent or received.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **Email** in the **Trigger on** field.
A list of options for the email trigger will appear for you to configure.
2. Choose one of the following server types as the trigger for your incoming emails:

Server type	Steps
Microsoft Outlook	Click Outlook . Microsoft Outlook is set as the email service and the bot is triggered when you receive a new email.

Email server

Click **Email server**.

- a)** Enter the email service **Host** information.

For example, if you are using Office365 as your email service, enter `Outlook.office365.com`.

- b)** Select **IMAP** or **POP3**.

IMAP and POP3 are protocols used to connect to the mail server that enables you to read your emails through an email client. By default **IMAP** is selected.

Note: The POP3 protocol has a known limitation where any new calendar invite can also trigger the bot.

- c)** **Use secure connection (SSL/TLS):**

This option is selected by default. This option enables you to use a secure connection with the mail server.

- d)** Enter the configured port number for your email server in the **Port** field.

- e)** Select one of the following user authentication methods to sign in to the email server:

- **Basic**

- **Credential:** Click **Pick** to select the stored **Username** and **Password**.
- **Variable:** Specify a variable.
- **Insecure string:** Enter the username and password.

- **OAuth 2.0 - Client credentials**

- Specify the unique client and tenant IDs generated when you registered the application in the Microsoft Azure portal.
- Specify the username you want to use to access the mail server.
- Specify the client secret that you generated for your app in the app registration portal.

For **Client ID**, **Tenant ID**, **Username** and **Client Secret**

- **Credential:** Use a value available in the credential

EWS server

Click **EWS server**.

a) From the **Microsoft Exchange Version** drop-down menu, select the version that your organization is using.

- Exchange Server 2013
The Microsoft Exchange Server 2019 is now supported. Therefore, if your organization is using the Exchange Server 2013, 2016 or 2019 versions of the Microsoft Exchange Server, select **Exchange Server 2013**.
- Exchange2010_SP2
- Exchange2010_SP1
- Exchange2010
- Exchange2007_SP1

For example, if you are using Microsoft Exchange Service Pack 2, select **Exchange2010_SP2** as your email service.

b) Enter the domain name, for example, `smtp.office365.com`

c) Select one of the following user authentication methods to sign in to the email server:

- **Basic**
 - **Credential:** Click **Pick** to select the stored **Username** and **Password**.
 - **Variable:** Specify a variable.
 - **Insecure string:** Enter the username and password.
- **OAuth 2.0 - Client credentials**
 - Specify the unique client and tenant IDs generated when you registered the application in the Microsoft Azure portal.
 - Specify the username you want to use to access the mail server.
 - Specify the client secret that you generated for your app in the app registration portal.

For **Client ID**, **Tenant ID**, **Username** and **Client Secret** fields, choose from the following:

3. Specify a time in the **Check every** field for all the server types to set the trigger interval.
The trigger interval for the bot is set to 120 seconds by default. You can also specify the minutes.

Note: The trigger interval that you have configured using the **Check every** drop-down menu does not depend on the number of emails received during the scheduled interval.

4. Specify an email event for the selected server type in the **Select Conditions** fields.
 - **Email from:** Specify the email addresses.
 - **Email subject contains:** Specify that an email contains a condition.
 - **Email without an attachment**
 - **Email with an attachment**
 - **Email in folder:** Specify an email in a folder.

Note: When you select the **Email subject contains** check box, the email trigger is executed depending on the following subject conditions:

- When the subject line is provided within double quotation marks (""), for example, "ABC spreadsheet", the trigger is executed only when the email subject has an exact match for the string provided within quotation marks.
- When multiple subject lines are separated by semicolons, for example, ABC spreadsheet; ABC project logs, the trigger is executed when the email subject matches any of the subject lines mentioned.

-
5. Specify your variable in the **Assigned to** field.
You can use this variable to retrieve various details about the email that triggered the bot, such as sender, recipient, subject, email content, date, action information, email server host, and port data.
You can select from the following:
 - **Multiple variables**
 - **Record**
 6. Click **Save** to save your configuration.
You have configured the email trigger for use with the trigger loop handle.

Using File Trigger in Trigger loop Handle

You can use the file trigger to trigger on file events.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **File** in the **Trigger on** field.
A list of options for the file trigger will appear for you to configure.
2. Select your file in the **File** field.
3. Specify the action in the **Start the bot when the file is** field.
This option allows you to specify when your bot starts based on the modifications to your file. You can choose from when the file is **created**, **deleted**, **renamed**, or **modified**.
4. Optional: Select the **Also start if it already exists** to start an existing bot.

5. Optional: In the **Assigned to** field, specify a variable to assign variable to this file.
6. Click **Save** to save your configuration.
You have configured the file trigger for use with the trigger loop handle.

Using Folder Trigger in Trigger loop Handle

You can use the folder trigger to trigger on folder events.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **Folder** in the **Trigger on** field.
A list of options for the folder trigger will appear for you to configure.
2. Select your folder in the **Folder** field.
3. Specify the action in the **Start the bot when** field.
This option allows you to specify when your bot starts based on the modifications to your folder.
You can choose from when the folder is **created**, **renamed**, or **deleted**. In addition, you can also select a file when it is **created**, **changed**, or **renamed**.
4. Optional: Select the **Monitor all folders under the folder path** option to monitor your folder.
5. Optional: Select the **Also start if it already exists** to start an existing bot.

Note: This additional option will only show for folders.

6. Optional: In the **Assigned to** field, specify a variable to assign variable to this folder.
7. Click **Save** to save your configuration.
You have configured the folder trigger for use with the trigger loop handle.

Using Hot key Trigger in Trigger loop Handle

You can use the Hot key trigger to trigger on key press events.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **Hot key** in the **Trigger on** field.
A list of options for the Hot key trigger will appear for you to configure.
2. Select a modifier and key in the **Hot key** field.
You can specify hot key with a list of available modifiers and keys that you can select.
For modifiers

- **Win**
- **Ctrl**
- **Shift**
- **Alt**
- **AltGr**

For hot keys

- **Letters:** This spans from letters A to Z.
- **Numbers:** This spans from numbers 0 to 9.

- **Special Characters:** This is a variety of special characters.
 - **Controls:** This is a variety of keyboard controls from Esc key to volume controls.
 - **Numpad:** This is a variety of numpad keys.
 - **Function Keys:** This spans from F1 to F12 keys.
 - **Arrows:** This is a variety of directional keys.
 - **Multimedia Keys:** This is a variety of functions for the browser and volume.
3. Click **Save** to save your configuration.
You have configured the hot key trigger for use with the trigger loop handle.

Using Form Trigger in Trigger loop Handle

You can use the form trigger to trigger on form element events.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **Form** in the **Trigger on** field.
A list of options for the form trigger will appear for you to configure.
2. Select a variable in the **Form name** field.
You can create a new variable as well, where you specify the variable name, its use as in input or output, and upload an existing form.
3. Select a element variable in the **Form element** field.
The list should be available for you to select when there is an element in your form.
4. Select an action in the **Select action trigger** field.
 - **Lost focus:** Button is clicked.
 - **Got focus:** Input field is clicked.
 - **Lost focus:** User leaves the input field.
 - **Changed value:** Check box or radio button status is changed.
 - **Value selected:** Check box is selected.
 - **Value unselected:** Check box is deselected.
5. Optional: In the **Assigned to** field, specify a variable to assign variable to this form.
This assigns the value from the specified form element to this variable
6. Click **Save** to save your configuration.
You have configured the form trigger for use with the trigger loop handle.

Using Object Trigger in Trigger loop Handle

You can use the object trigger to start the bot when the Select main event takes place on the trigger interface element.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **Object** in the **Trigger on** field.
A list of options for the object trigger will appear for you to configure.
2. Specify the window details the **Window detail**.
There are three options you can choose.

- **Variable:** Select a window variable.

Note: This is the default option.

- **Application:** Select a preset, this can be your **Currently active**, **Desktop**, and **Taskbar**.
- **Browser:** Select a browser tab.

3. Select **Capture object** to start the capture.

4. Select an event type.

5. Click **Save** to save your configuration.

You have configured the object trigger for use with the trigger loop handle.

Using Microsoft 365 Outlook trigger in Trigger loop: Handle

You can use the email trigger to start a bot when you receive an email after connecting to the Microsoft 365 Outlook server using the OAuth 2.0 authentication.

Ensure that in Automation Workspace, you have used the **Trigger loop** package to add the **Trigger loop** to your bot.

1. In the **Trigger loop**, select **Trigger loop: Handle**.
2. Click the **Trigger on** drop-down menu and select **Microsoft 365 Outlook Trigger > Email**.
3. Click the **Azure Cloud** drop-down menu and select one of the following options:
 - **Azure Global:** For the Microsoft 365 Commercial version (login.microsoftonline.com)
 - **Azure GCC High:** For the Microsoft 365 Government version (login.microsoftonline.us)
4. Use the **Check every** field to specify or set the trigger interval time.
The trigger interval for the bot is set to **120** minutes by default.
(Optional) Click the **Minutes** drop-down menu to change the value to **Seconds**.
5. Click the **Authentication mode** drop-down menu and select **Client Credentials**.
For more information on setting up OAuth 2.0 to use client credentials, see [Set up OAuth 2.0 using client credentials](#) on page 2746.
6. For the **Client ID**, **Tenant ID**, **Username** and **Client Secret** fields, select one of the following tabs:
 - **Credential:** Click **Pick** to select a value from the credential vault.
 - **Variable:** Specify a variable.
 - **Insecure String:** Enter a value or click the **Insert a value** icon to select an existing variable.
7. (Optional) Use the **Select Conditions** field to select any or all of the following options for email events from the selected server type:
 - **Email from:** Enter the email addresses or click the **Insert a value** icon to select an existing variable.
 - **Email subject contains:** Enter a condition for the email subject line.
For example, you can enter 'Sales report' as a condition to trigger a bot when you receive any email that contains the subject line as 'Sales report'. You can also click the **Insert a value** icon to select an existing variable.
 - **Email attachment:** Select one of the following email attachment options:
 - **With attachment**

- **Without attachment**

- **Email in folder:** Enter the filepath of the email folder.

For example, if you want to trigger a bot when you receive an email in Microsoft 365 Outlook folder called 'Sales', enter `inbox/sales`. You can also click the **Insert a value** icon to select an existing variable.

8. Use the **Assigned to (optional)** field to select one of the following tabs:

- **Multiple variables:** Click **Add variable mapping** to associate a key with a variable.
- **Record:** Use the **Assigned to** drop-down menu to assign an existing variable or click the **Create variable** icon to create a variable that you want to assign.

Note: You can use this variable to retrieve various details about the email that triggered the bot, such as sender, recipient, subject, email content, date, action information, email server host, and port data.

9. Click **Save** to save your configuration.

Microsoft 365 Outlook is now configured within the trigger loop handle of a bot.

Use Process Trigger in Trigger loop Handle

You can use the process trigger to trigger on process events.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **Process** in the **Trigger on** field.
A list of options for the process trigger will appear for you to configure.
2. Select your process in the **Process** field.
3. Specify the action in the **Start the bot when the process** field.
This option allows you to specify when your bot starts based on the modifications to your file.
 - **Starts**
 - **Stops**
4. Optional: In the **Assigned to** field, specify a variable to assign variable to this process.
5. Click **Save** to save your configuration.
You have configured the process trigger for use with the trigger loop handle.

Using Service Trigger in Trigger loop Handle

You can use the service trigger to start the bot when service start, stop, pause, or resume.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **Service** in the **Trigger on** field.
A list of options for the service trigger will appear for you to configure.
2. Select your bot in the first field.
3. Specify the action in the **Start the bot when the service** field.

This option allows you to specify when your bot starts based on the modifications to your service.

- **Starts**
- **Stops**
- **Resumes**
- **Pauses**
- **Is running**
- **Has stopped**
- **Is paused**

4. Optional: In the **Assigned to** field, specify a variable to assign variable to this service.

5. Click **Save** to save your configuration.

You have configured the service trigger for use with the trigger loop handle.

Using ServiceNow New Record Trigger in Trigger loop Handle

You can use the ServiceNow new record trigger to monitor a ServiceNow table for new records.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **ServiceNow > New Record Trigger** in the **Trigger on** field.

A list of options for the processServiceNow new record trigger will appear for you to configure.

2. Optional: Enter the API version in the **API version** field.

3. Specify the credential fields for **Client ID**, **Client secret**, **Username**, and **Password** fields.

- **Credential**: Select a credential in the credential vault.
- **Variable**: Specify a variable.
- **Insecure string**: Enter a string.

4. Enter the **Table name** to monitor for new records.

A query is sent, and ServiceNow returns data for this table. When a new record is returned in the data, then this trigger is invoked.

5. Optional: Select an input where the ServiceNow response is stored in the **File names** field.

For **Variable**, specify a variable.

For **List**, the following can be selected:

- **Any**: Specify a value.
- **String**: Specify a value.
- **Number**: Specify a value.
- **Datetime**: Select the date, time, and time zone, or choose a **Variable**.
- **Boolean**: Select a **True** or **False** option, or choose a **Variable**.
- **File**: Specify a value for **Variable**, **Control room file**, or **Desktop file**

6. Optional: Specify the filter in the **Filter by records** field.

For **Query**, specify a query.

For **Number-value pair**, specify a dictionary or variable for **Dictionary** or add an entry for **Entry list**.

7. Specify a time in the **Check every** field to set the trigger interval.

The trigger interval for the bot is set to 120 seconds.

8. Specify your variable in the **Assigned to** field.

You can use this variable to retrieve various details about the email that triggered the bot, such as sender, recipient, subject, email content, date, action information, email server host, and port data.

You can select from the following:

- **Multiple variables**
- **Record**

9. Click **Save** to save your configuration.

You have configured the ServiceNow new record trigger for use with the trigger loop handle.

Using ServiceNow Updated Record Trigger in Trigger loop Handle

You can use the ServiceNow updated record trigger to monitor a ServiceNow table for updated records.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **ServiceNow > Updated Record Trigger** in the **Trigger on** field.

A list of options for the processServiceNow new record trigger will appear for you to configure.

2. Optional: Enter the API version in the **API version** field.
3. Specify the credential fields for **Client ID**, **Client secret**, **Username**, and **Password** fields.

- **Credential**: Select a credential in the credential vault.
- **Variable**: Specify a variable.
- **Insecure string**: Enter a string.

4. Enter the **Table name** to monitor for new records.

A query is sent, and ServiceNow returns data for this table. When a new record is returned in the data, then this trigger is invoked.

5. Optional: Select an input where the ServiceNow response is stored in the **File names** field.

For **Variable**, specify a variable.

For **List**, the following can be selected:

- **Any**: Specify a value.
- **String**: Specify a value.
- **Number**: Specify a value.
- **Datetime**: Select the date, time, and time zone, or choose a **Variable**.
- **Boolean**: Select a **True** or **False** option, or choose a **Variable**.
- **File**: Specify a value for **Variable**, **Control room file**, or **Desktop file**

6. Optional: Specify the filter in the **Filter by records** field.

For **Sys_id**, specify the ID

For **Query**, specify a query.

For **Number-value pair**, specify a dictionary or variable for **Dictionary** or add an entry for **Entry list**.

7. Specify a time in the **Check every** field to set the trigger interval.
The trigger interval for the bot is set to 120 seconds.
8. Specify your variable in the **Assigned to** field.
You can use this variable to retrieve various details about the email that triggered the bot, such as sender, recipient, subject, email content, date, action information, email server host, and port data.
You can select from the following:
 - **Multiple variables**
 - **Record**
9. Click **Save** to save your configuration.
You have configured the ServiceNow new record trigger for use with the trigger loop handle.

Using Window Trigger in Trigger loop Handle

You can use the window trigger to start the bot base on window events.

In Automation Workspace, you added the **Trigger loop Handle** to your bot.

1. In the **Trigger loop Handle**, select **Window** in the **Trigger on** field.
A list of options for the window trigger will appear for you to configure.
2. Select your application or variable in the **Window** field.
3. Specify the action in the **Window action that starts the bot** field.
This option allows you to specify when your bot starts based on the modifications to your window.
 - **Open**
 - **Close**
4. Optional: In the **Assigned to** field, specify a variable to assign variable to this window.
5. Click **Save** to save your configuration.
You have configured the window trigger for use with the trigger loop handle.

V11 Task Bot package

The V11 Task Bot package enables you to run an Enterprise 11 bot from Automation 360 in the Enterprise 11 Control Room.

Actions in the V11 Task Bot package

The package includes the following action:

Action	Description
Run	See Using Run action on page 3020.

Related reference

[V11 Task Bot package updates](#) on page 916

Review the updates in released versions of packagesuch as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Using Run action

Use the **Run** action to run an Enterprise 11 bot from Automation 360 in the Enterprise 11 Control Room.

Ensure that the Enterprise 11 user credential that you want to use to run the Enterprise 11 bot includes the following:

- Access to the Enterprise 11 Bot Runner device on which you want to run the Enterprise 11 bots
- **Run my bots** and **View my scheduled bots** permissions

To use the **Send callback status to A2019** option, ensure the following:

- The IP address of the Automation 360 Bot Runner device on which you want to run the Automation 360 bot is a static IP address
- The IP address is available in the callback URL of the Enterprise 11 Control Room

[Callback URLs for bot deployment](#)

1. Double-click or drag the **Run** action from the **V11 Task Bot** node in the **Actions** palette.
2. Provide the Enterprise 11 Control Room URL in which you want to run the bot.
3. Click the **Credential** tab to use a value from the Credential Vault and the **Variable** to use a credential variable.

Alternatively, click the **Insecure string** tab to manually specify the value you want to use as the **Username** and **Password** to log in the Control Room you have specified.

4. Specify the location of the bot you want to run in the **Task relative path** field.
5. Optional: Specify the device on which you want to run the bot in the **Bot Runner device name** field.

You can specify multiple devices separated by a semicolon. Ensure that the names of the devices you have provided are the same as those on the **My Devices** page of the Enterprise 11 Control Room.

If you do not provide any value in the field, the system runs the bot on any connected devices (device for which the user specified in the Step 3).

6. Select the **Run bot runner session on Control Room** check box to deploy the bot using the remote desktop process.
7. Select the **Wait for task to complete** check box if you want the system to wait for the task to complete before performing the next action in the bot.
 - a) Specify the period you want the system to wait before the bot is timed out in the **Total wait time** field.
 - b) Select the version of the Control Room on which you want to run the bot.

- 11.3.2 or later (includes 11.3.3.x releases):

Click **Advanced settings** to expand and update the polling attributes.

Field	Description
Wait time before start polling the status	Period (in seconds) you want the system to wait before it starts polling the status after the bot is deployed on the device.
Polling interval for non-started execution	Time interval at which you want the system to poll for status for the Enterprise 11 bot you have set to run but has not started execution.
Polling interval for pending execution	Time interval at which you want the system to poll for status for the bot that you have set to run and is pending execution.
Polling interval for paused execution	Time interval at which you want the system to poll for status for the bot that has started execution and is paused.
Polling interval for in-progress execution	Time interval at which you want the system to poll for status for the bot that has started execution and is currently in progress.
Polling interval for unknown execution	Time interval at which you want the system to poll for status for the bot that has started execution and the current status is unknown.

- 11.3.4 or later:
 - Select the **Send callback status to A2019** option to specify a range for the TCP port that you want to use to send the callback status to Automation 360.

Field	Description
From available TCP port	Starting value in the range for the TCP port that you want to use to send the callback status.
To available TCP port	End value in the range for the TCP port that you want to use to send the callback status.

Note: The IP address of the Automation 360 Bot Runner must be reachable from Enterprise 11 Control Room on the range for the TCP port you have provided.

- Select the **Poll status from 11.x Control Room** option. Click **Advanced settings** to update the polling status from the Enterprise 11 Control Room:

Field	Description
Wait time before start polling the status	Period (in seconds) you want the system to wait before it starts polling the status after the bot is deployed on the device.
Polling interval for non-started execution	Time interval at which you want the system to poll for status for the Enterprise 11 bot you have set to run but has not started execution.
Polling interval for pending execution	Time interval at which you want the system to poll for status for the bot that you have set to run and is pending execution.
Polling interval for paused execution	Time interval at which you want the system to poll for status for the bot that has started execution and is paused.
Polling interval for in-progress execution	Time interval at which you want the system to poll for status for the bot that has started execution and is currently in progress.
Polling interval for unknown execution	Time interval at which you want the system to poll for status for the bot that has started execution and the current status is unknown.

8. Select the dictionary variable from the **Input parameters** list that you want to use to pass input parameters for the bot.

The input variables that you want to pass for the bot are contained as keys in the dictionary variable with their corresponding values.

9. Select the dictionary variable that you want to use to store the output from the **Assign the output to** list.

The dictionary variable stores the output parameters of the Enterprise 11 bot as keys.

Additionally, the following keys are added in the dictionary variable by default:

Key	Value
COMMAND	Name of the command that was last executed by the Enterprise 11 bot.
STATUS	Status of the Enterprise 11 bot execution.
START_TIME	Time when execution of the Enterprise 11 bot started.

Key	Value
END_TIME	Time when execution of the Enterprise 11 bot ended.
AUTOMATION_NAME	Name of the automation

10. Click **Save**.

VBScript package

The VBScript package contains actions that enable VBScript functions in a task.

Before you start

1. Verify that the device on which you want to run the VBScript has Windows operating system installed.
2. Open a VBScript file, or input the script you want to run using the **Open** action. You must associate the details of the file or script you want to run with a session name. Use this same session name for other VBScript actions.
3. Use the **Run function** action to execute a function within the script or execute the entire script. You must use the VBScript session name you established in the previous step.
4. After you have executed the script, close the VBScript session.

To review the bot launcher logs, navigate to `C:\ProgramData\AutomationAnywhere\BotRunner\Logs\<current month>\Bot_Launcher-<today's date>.log.zip`. Each zipped folder contains a file with data on the code execution, which is useful for debugging.

Actions in the VBScript package

The VBScript package includes the following actions:

Note: The **Open** action must be the first action to use the VBScript in a task.

Action	Description
Close	See Close action in VBScript on page 3024.
Run function	See Run function action in VBScript on page 3024.
Open	See Open action in VBScript on page 3025.

Related tasks

[Example of using the VBScript package in a resilient bot](#) on page 3107

Build a bot that executes a Microsoft Visual Basic script. Use the Try/Catch package to gracefully end the bot if it fails, making it resilient to crashes. A resilient bot allows scheduled and queued bots to continue even if the current bot encounters an error.

Related reference

[VBScript package updates](#) on page 917

Review the updates in released versions of the VBScript package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Close action in VBScript

This action enables you to close the session in VBScript.

Settings

Closes the session.

Specify the same session name from the **Open** action in VBScript.

Run function action in VBScript

You can run a function within VBScript using the Run function action.

Settings

Runs a function within the VBScript.

- In the VBScript **session** field, specify a session name. Use the same session name from the **Open** action in VBScript.
- Optional: Specify the function name to run and the arguments to pass to the function.

Note: You can pass only a list variable as an argument for the function. You can use the list variable to pass multiple arguments of different data types such as Boolean, datetime, number, and string.

- Optional: If the specified function returns a value, specify the variable to store that value in the **Assign the output to variable** field. The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Note: In VBScript, stand alone scripts do not return a value.

Open action in VBScript

This action enables you to open a VBScript file.

Settings

Opens a VBScript file.

- In the VBScript **session** field, specify a session name. Use this same session name for other VBScript actions.
- In the VBScript , choose one of the following options:
 - In the **Import existing file** option, select an existing VBScript file.

Note: If you are uploading a script from a file on your desktop, the file and any dependencies must be in a standalone folder. When you select a file for upload, all files and folders at the same folder level are uploaded.

- In the **Manual input** option, enter the VBScript.

Wait package

Use the actions in the Wait package to add a condition to wait for an application screen to change, or a separate window to open or close before proceeding to the next action.

Actions in the Wait package

The Wait package includes the following actions:

Action	Description
Wait for condition	See Wait for condition action on page 3026
Wait for screen change	See Using Wait for screen change action on page 3027.
Wait for window	See Using Wait for window action on page 3030.

Related reference

[Wait package updates](#) on page 918

Review the updates in released versions of the Wait package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Wait for condition action

Makes the bot wait until a specific condition is true before executing the next action.

Settings

In the **Wait till** field, specify the condition to meet. For example, the wait condition can be based on whether an application is running, a folder or file exists, a variable matches the specified value, an application window exists, or a machine or server is running.

Note:

- If a bot encounters an internal error that does not appear on the UI, it does not wait for the amount of time that is specified in this action. The bot does not stop and continues to the next line.
- When you create a bot and use the variable option to search the window title and use the condition **Window exists**, or **Window does not exist** the bot will not search for the changed window title. Also, it will not identify the window title if you have changed the variable. You can use the condition **Window with same title does not exist**, or **Window with same title exist** to verify whether a window with the same title exists or changed.

When you use the **Object does not exist** condition to verify whether a specific object exists in a window, and if the object exists, the result of the condition will be false. In this scenario, the bot keeps waiting until the specified condition is true, that is, the bot waits till the object does not exist in a window and then executes the next action.

Note: The value that you enter in the **Keep trying for (seconds)** field when you select Recorder conditions is not the wait time for the specified condition. This time is a timeout to search an object from the window. For example, if you specify a value of 15 seconds in the field, then the Recorder will take a maximum of 15 seconds to send the result to the **Wait for condition** action, that is whether the object exists in a window.

This action offers the same conditions as the If package. See the [If package](#) on page 2619.

Group conditions

Use the **Add group** option to add multiple Boolean conditions or combine more than one conditions with **And** and **Or** options within a group and when you want the bot to check multiple conditions at a time before executing a set of .

You can also add a group within a group.

Using Wait for screen change action

Use the **Wait for screen change** action to wait for the content of a specific screen or the entire window to change before executing the next action.

For example, a Human Resources (HR) personnel automating leave-management tasks wants to log in to the HR portal. After entering the user credentials, this action enables the automation task to wait until the next screen loads.

1. In the **Actions** palette, double-click or drag the **Wait for screen change** action from the Wait package.
2. In the **Screen change relative to** field, choose **Window** or **Screen**.
3. Select an application window:

Option	Steps
<p>Application</p>	<p>From the drop-down list, select the window title from the open applications.</p> <ul style="list-style-type: none"> The Window title field displays the title of the application window you have selected. <p>Insert a wildcard character (*) in the Window title field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has Microsoft in the title, use a wildcard to indicate any string by adding it before or after the value: *Microsoft*. The first searches for the exact window title (Microsoft), and if it does not find a match, it searches for windows with the term Microsoft anywhere in the title.</p> <p>You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either String or a Pattern and then enter the value. By default, the Window title field is case-sensitive.</p> <p>To identify a browser title, you can enable the Case sensitive option to match the letter case, or disable the option to identify a window title where the letter case does not match.</p> <hr/> <p>Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).</p> <hr/> <p>For example, you can enter the String value as ((\w*) -Notepad for all window title names starting with ((\w*) -Notepad, or use Pattern value as ((\w) \s) *document-Notepad for only those window titles that match this pattern.</p> <hr/> <p>Note:</p> <ul style="list-style-type: none"> When you use a regular expression of type String with -title as the input value for a window title in any , the might encounter a run time

input as ^-title, the application with the specific title is open. The asterisk (*) is just a character, not a wild card

Option	Steps
Browser	Select from a list of supported browser tabs. Note: This option supports , Chromium-based , and browsers.
Variable	Use a window variable to specify the application window you want to use.

4. Optional: Select the **Resize window** option to specify the window dimensions. This option delivers a more reliable bot. It resizes the window to the dimensions at which the task was recorded, which enhances the ability of the bot to identify the target object.
- If the window is maximized when you record the task, this option is not selected.
 - If the window is not at the maximum size when you record the task, this option is selected, by default, and the width and height fields are automatically filled with the dimensions of the window.

Note: This option is available only for windows that can be resized. It is not available for the **Desktop** or **Taskbar** options.

5. Click **Capture region**.
The selected window appears.
6. Drag the mouse to draw a rectangle around the region that you want to capture and right-click when done.
The captured area appears in the **Preview** section, followed by the image coordinates **X, Y, Width, and Height**.
7. In the **How long to wait before comparing screens?** field, specify the wait time (in seconds) to begin comparing the window or screen.
When a difference is detected, the comparison stops and the task proceeds to the next action.
8. In the **How long to wait before screen comparing is stopped?** field, specify the wait time (in seconds) for the screen to change.
If the screen does not change within the time you specified, the task proceeds with the next action.
9. Select the **Throw an exception if the screen is not changed** option to show an error message and terminate the bot if the screen does not change.
If the option is deselected and the screen does not change, the task proceeds with the next action.
10. Click **Save**.

Using Wait for window action

Use the **Wait for window** action to wait for the specified window to open or close before executing the next action.

For example, a Human Resources (HR) personnel automating leave-management tasks might require the attendance application to open before they enter the user credentials. This action enables the automation task to wait until the application window opens.

1. In the **Actions** palette, double-click or drag the **Wait for window** action from the Wait package.
2. In the **Wait for window** field, select the option you want the automation to wait for:
 - **Wait for window to open**
 - **Wait for window to close**
3. Select an application window:

Option	Steps
<p>Application</p>	<p>From the drop-down list, select the window title from the open applications.</p> <ul style="list-style-type: none"> The Window title field displays the title of the application window you have selected. <p>Insert a wildcard character (*) in the Window title field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has Microsoft in the title, use a wildcard to indicate any string by adding it before or after the value: *Microsoft*. The first searches for the exact window title (Microsoft), and if it does not find a match, it searches for windows with the term Microsoft anywhere in the title.</p> <p>You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either String or a Pattern and then enter the value. By default, the Window title field is case-sensitive.</p> <p>To identify a browser title, you can enable the Case sensitive option to match the letter case, or disable the option to identify a window title where the letter case does not match.</p> <hr/> <p>Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).</p> <hr/> <p>For example, you can enter the String value as ((\w*)-Notepad for all window title names starting with ((\w*)-Notepad, or use Pattern value as ((\w)\s)*document-Notepad for only those window titles that match this pattern.</p> <hr/> <p>Note:</p> <ul style="list-style-type: none"> When you use a regular expression of type String with -title as the input value for a window title in any , the might encounter a run time

input as ^-title, the application with the specific title is open. The asterisk (*) is just a character, not a wild card

Option	Steps
Browser	Select from a list of supported browser tabs. Note: This option supports , Chromium-based , and browsers.
Variable	Use a window variable to specify the application window you want to use.

4. In the **How long you would like to wait for this condition to be true?** field, specify the wait time (in seconds) for the window to open or close.
If the window does not open or close within the time you specify, the task proceeds to execute the next set of actions.
5. Select the **Throw an exception if wait for window is unsuccessful** option to show an error message and terminate the bot if the window does not open or close within the specified amount of time.
If the option is deselected and the window does not open or close within the specified amount of time, the task proceeds with the next action.
6. Click **Save**.

Workday package

Workday is a leading provider of enterprise cloud applications that helps organizations manage various HR, finance, and business processes, including payroll, and more. The Automation 360 Workday package uses the Workday Web Services (set of SOAP APIs) to read and write data in and out of Workday.

The Workday package has a deep API-level integration with Workday that allows you to build automations and eliminates the need to program. It is aimed at automating Workday processes like reporting, data upload/download, or triggering work flows. To start interacting with Workday, use the authenticate action from the Workday package to authenticate from Automation 360. After you authenticate, you can retrieve reports, launch EIB (Enterprise Interface Builder), and get integration status using various actions in the Automation Anywhere Control Room. The following diagram provides an overview of the actions performed between Automation 360 and Workday:

The following video shows how Workday can be used along with ServiceNow to automate a use case where HR creates the open positions in Workday by launching an Enterprise Interface Builder (EIB) from Automation 360:

[Workday package updates](#) on page 920

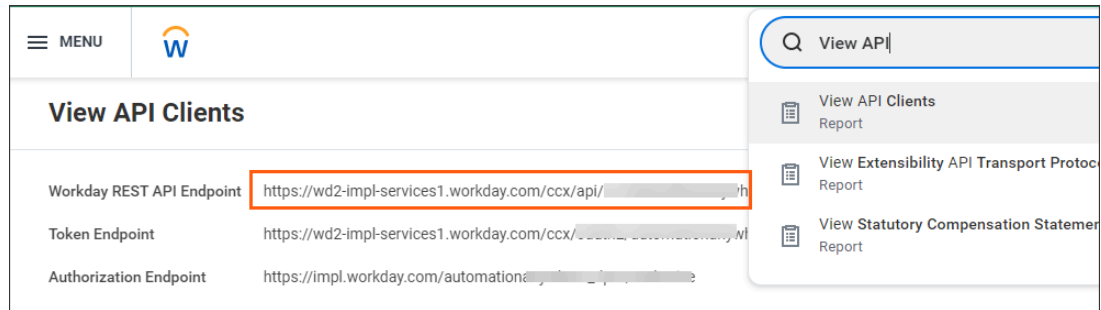

Review the updates in released versions of the Workday package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Workday Authentication action

Workday Authentication action is the first command action that you need to call to get authenticated with your Workday instance.

- To authenticate to Workday, you need to know your Environment base URL (domain), Tenant ID, Username, and Password.
- Log in to the Workday as an admin. For more information on logging in to a Workday instance, see [Workday Login](#).

- To find the base URL (domain) and tenant of your Workday environment, search for View API Clients. You will be able to derive the base URL from the Workday REST API Endpoint field. The format is `https://{domain}.workday.com/ccx/api/v1/{tenant}`.
- The base URL is `https://{domain}.workday.com/`. For example, if the Workday REST API Endpoint is `https://wd2-impl-services1.workday.com/ccx/api/v1/yourtenant_abc`, your base URL is `https://wd2-impl-services1.workday.com`

- The tenant is derived from the Workday REST API Endpoint field as well. For example, if the Workday REST API Endpoint is `https://wd2-impl-services1.workday.com/ccx/api/v1/yourtenant_abc`, your tenant is `yourtenant_abc`
- Create a new .
 - Log in to your instance of the .
 - On the left panel, click **Automation**.
 - Click **Create new > Bot**.
 - In the **Create Task Bot** window, enter the name.
 - Accept the default folder location: `\Bots\`
To change the default storage location, click **Choose** and follow the prompts.
 - Click **Create and edit**.
 - From the Actions pane, select **Workday > Authentication** and place it under the **Start** of the bot flow.
 - In the **Environment** field, enter the **base URL** copied from Workday.
 - In the **Tenant** field, paste the **tenant** copied from Workday.
 - Enter the Workday Username. Select one of the following options to specify the **Username**:
 - Credential**: Enables you to use a value available in the Credential Vault that contains information about the Username/Password. For more information on creating a credential, see [Set up lockers and credentials in Credential Vault](#) on page 1797.
 - Variable**: Enables you to use a credential variable that contains information about the Username/Password. For more information on creating a variable, see [Credentials and credential variables in the Bot editor](#) on page 2254.
 - Insecure string**: Enables you to manually enter the Username/Password for the Workday Authentication.

- d) Enter the Workday Password. Select one of the following options to specify the **Password**:
- **Credential**: Enables you to use a value available in the Credential Vault that contains information about the Username/Password. For more information on creating a credential, see [Set up lockers and credentials in Credential Vault](#) on page 1797.
 - **Variable**: Enables you to use a credential variable that contains information about the Username/Password. For more information on creating a variable, see [Credentials and credential variables in the Bot editor](#) on page 2254.
 - **Insecure string**: Enables you to manually enter the Username/Password for the Workday Authentication.
- e) Enter Default as the session name or create a session of type **Workday Session**.

The screenshot displays the Automation Anywhere Bot Editor interface. On the left, the 'Test' workflow is visible, with the 'Workday: Authentication' step highlighted. The right-hand pane shows the configuration for this step. The configuration includes the following fields:

- Environment**: `https://wd2-impl-services1.workday.com/` (labeled 'a')
- Tenant**: `auton` (labeled 'b')
- Username**: `Credential` (labeled 'c')
- Password**: `Credential` (labeled 'd')
- Create Workday session**: `Local session` (labeled 'e')
- Local session name**: `Default`

Workday Launch EIB action

With the Workday Launch EIB(Enterprise Interface Builder) action, you can invoke an inbound or an outbound EIB using the IntegrationSystemID or WorkdayID. An EIB is a tool to get data out of Workday (Outbound EIB) or get data into Workday (Inbound EIB)

Ensure that you are authenticated before initiating any Workday action. For more details, see [Workday Authentication action](#). You have the option to launch Inbound or Outbound EIB. Below are the prerequisites for each of these options:

- For Inbound Workday EIBs - Use to load data into your Workday system by downloading EIB template as a file attachment or file transfer from the Control Room. For example, sending an employee record file with the employee's details to Workday creates a new record entry.
 - Log in to Workday as an admin. For more information on logging in to a Workday instance, see [Workday Login](#).
 - Open the EIB you want to launch.

- To get the Integration System ID or WID of the EIB, navigate to **Actions > Integration IDs > View IDs**.

The screenshot shows the 'View Integration System' page for 'Demo_Inbound_EIB'. The 'Actions' menu is open, and the 'View IDs' option is highlighted with a yellow box. The page displays basic details, system ID, comment, and configuration tabs.

Retrieval	File Name	File Type
Retrieval Method		Web Service Spread Template
Attach File at Launch		

The **Integration IDs** page appears with the Workday ID (WID) and Integration System ID.

- Copy either the Workday ID (WID) or Integration System ID.
 - For Outbound Workday EIBs - Use to export data from custom reports. You can use Outbound EIBs for simpler integrations. For example, when one data source is used (typically a report) and the transformation is simple enough to be done with a single custom transformation (XSLT) or Custom Report Transformation. For example, extracting employee salary information from Workday in order to send it to a 3rd party payroll system.
- In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Workday > Launch EIB**, and place it in the canvas.

- a) From the **Type of ID** drop-down select either the Workday ID (WID) or Integration System ID.
 - b) In the **ID** field, paste either the Workday ID (WID) or Integration System ID copied from Workday.
 - c) Select the **Type of integration**. Automation 360 supports launching both **Inbound** and **Outbound** integrations.
 - d) For the **Inbound** integration, you need to provide the integration template. For more information, see [Workday Launch EIB](#). The **Outbound** integration does not require a template.
 - e) Enter Default as the session name, or create a session of type **Workday Session**.
 - f) The Launch EIB action returns the Integration event ID. You can save it as a variable defined in **Integration event ID (optional)**.
 - g) The Launch EIB action also returns Details of the integration. You can save it as a variable defined in **Details (optional)**.
2. Verify that you can run the bot and launch an EIB. The following video will launch an EIB in Workday from Automation Anywhere Control Room. The video shows how the Workday status changes from Processing to Completed which confirms that the EIB has been successfully launched.

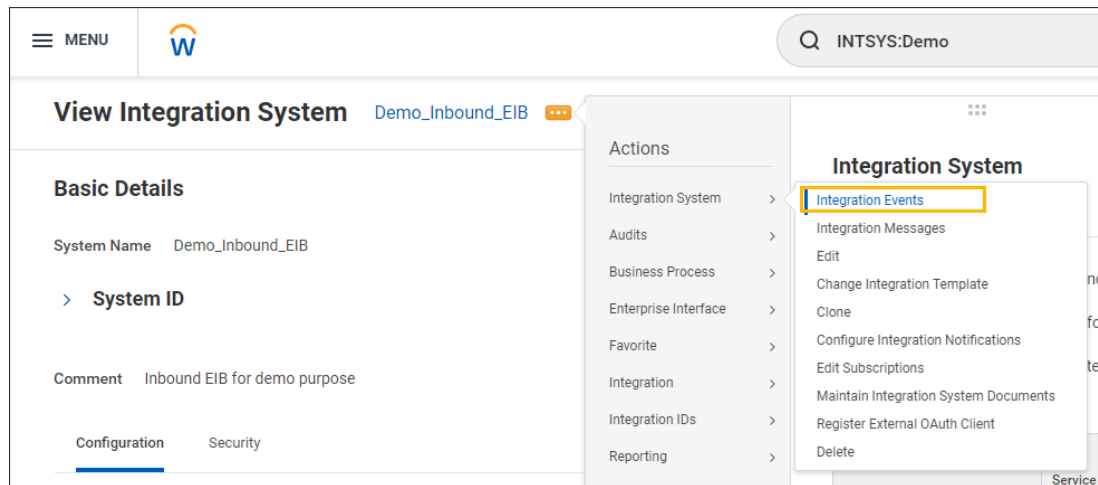

Tip: Use the Integration Event ID in [Workday Get Integration Event](#) action on page 3038 to get the current status of the integration.

Workday Get Integration Event action

You can use the **Get Integration Event** to monitor the progress of an EIB or other integrations in a Workday instance.

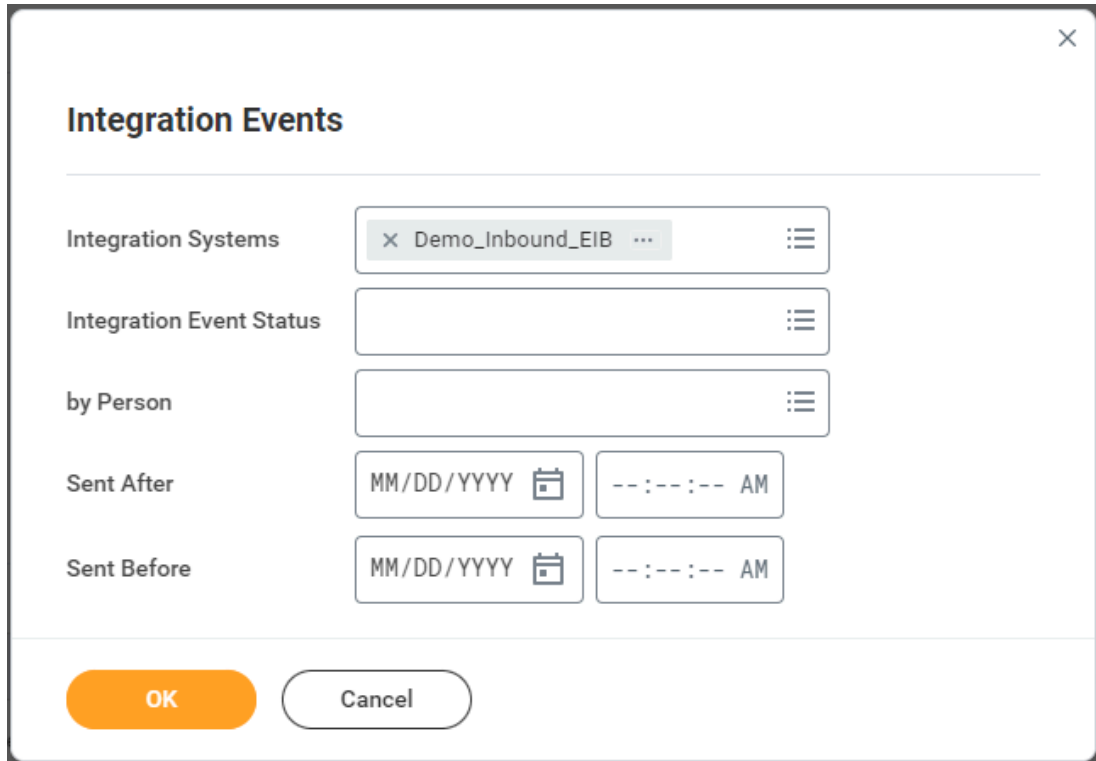

Ensure that you are authenticated before initiating any Workday action. For more details, see [Workday Authentication action](#). Below are the prerequisites for the **Get Integration event**:

- Log in to the Workday as an admin. For more information on logging in to a Workday instance, see [Workday Login](#).
- Open the EIB that contains the event you want to monitor.
- To review the Background Process Instance ID or WID of an EIB event:
 1. Navigate to **Actions > Integration System > Integration Events**.

The **Integration Events** screen appears.

2. Click **OK** to show all the integration events. You can also filter the results based on **Integration Event Status**, **by Person**, or by **Sent After/Sent Before** date and time.

The image shows a dialog box titled "Integration Events" with a close button (X) in the top right corner. The dialog contains several configuration fields:

- Integration Systems:** A dropdown menu with "Demo_Inbound_EIB" selected and a menu icon to its right.
- Integration Event Status:** An empty dropdown menu with a menu icon to its right.
- by Person:** An empty dropdown menu with a menu icon to its right.
- Sent After:** Two input fields. The first is a date field with the placeholder "MM/DD/YYYY" and a calendar icon. The second is a time field with the placeholder "--:--:-- AM".
- Sent Before:** Two input fields. The first is a date field with the placeholder "MM/DD/YYYY" and a calendar icon. The second is a time field with the placeholder "--:--:-- AM".

At the bottom of the dialog, there are two buttons: "OK" (orange) and "Cancel" (white with a grey border).

3. Select the EIB event you want to monitor. Navigate to **Actions > Integration IDs > View IDs**.

The screenshot shows the 'Integration Events' page in Automation Anywhere. The page title is 'Integration Events' and it shows 12 items. The selected integration system is 'Demo_Inbound_EIB'. The table below shows the details of the selected event:

Workday Integration Cloud Platform (ESB) Process IDs	Event Type	Integration Event	Integrati
bb55539d3ae1100170848a36794a0000	Integration Event	Demo_Inbound_EIB - 01/25/2023, 1:22:35.265 PM (Completed)	Demo_In

The context menu for the selected event includes the following actions:

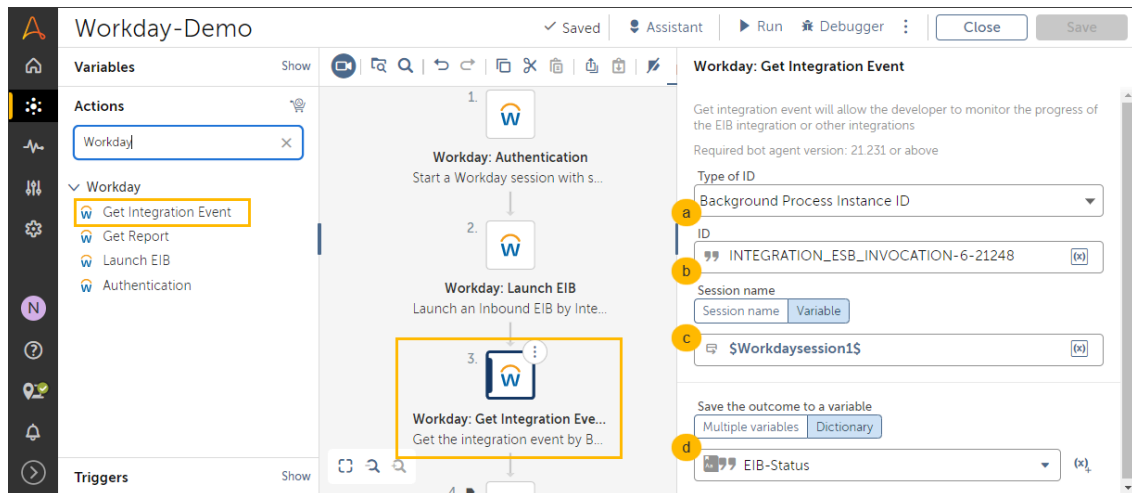

- Audits
- Background Process
- Favorite
- Integration IDs
- Integration System
- Reporting
- View IDs (highlighted)
- Edit Reference ID
- Maintain Reference IDs

The 'Background Process' modal window shows the following details:

- Created Date and Time:** 01/25/2023 04:22 PM
- Process:** Data Load
- Request:** Integration ESB Invocation
- Status:** Completed

The **Integration IDs** page appears with the Workday ID (WID) and Background Process Instance ID.

1. Copy either the Workday ID (WID) or Background Process Instance ID.
2. In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Workday > Get Integration Event**, and place it in the canvas.

- a) From the **Type of ID** drop-down, select either the Workday ID (WID) or Background Process Instance ID.
- b) In the **ID** field, paste either the Workday ID (WID) or Background Process Instance ID copied from Workday.
- c) Enter Default as the session name, or create a session of type **Workday Session**.
- d) Save the outcome to a variable. For example, you can store all the lines of the report in a Dictionary (EIB-Status).

Workday get report action

Use the Workday - Get Report action to retrieve a report using the Report URL. Workday Reports-as-a-Service (RaaS) is a feature that makes reports available as web services. While you are creating these reports in Workday, you must configure them as Advanced type reports to be web-service enabled.

Ensure that you are authenticated before initiating any Workday action. For more details, see [Workday Authentication action](#). Below are the prerequisites for the **Get Report event**:

- Log in to the Workday as an admin. For more information on logging in to a Workday instance, see [Workday Login](#).
- To find the report URL, click the horizontal three dots and navigate to **Actions > Web Service > View URLs**.

The **View URLs Web Service** page appears.

- Right-click **Workday XML** and select **Copy URL**.

1. In the Automation Anywhere Control Room, navigate to the **Actions** pane, select **Workday > Get Report**, and place it in the canvas.

- a) Paste the **Report URL** copied from Workday. The copied report URL is the report you want to get from Workday in Automation 360.
- b) Select the **Report Format**. Automation 360 supports **Simple Xml** and **Workday Xml** formats. **Workday Xml** contains more data elements (for example, WID (Workday ID)) than the **Simple Xml**.
- c) Enter Default as the session name.

- d) Save the outcome to a variable. For example, you can store all the lines of the report in a list (listReportData)
2. To verify that you can run the bot in Debug mode, set a breakpoint action next to **Get Report**. In the previous example, there is a Message box action. Open the listReportData variable to view the results.

Note: The output is retrieved as a list of type . To read an individual record (row) in this list, you need to loop through all the dictionary items using the action and read or extract the records (rows) individually. For example, the output of get multiple records is saved in the variable list_of_records_any. If the variable contains five records, then each record is passed to the Loop action to be processed one at a

time.

Window package

Use the Window package to automate tasks relating to the window.

Window is a data type available for storing application window titles. It is the only data type that can be used in all the actions of the **Window** package. Create a variable of data type **Window** and select or assign a window title.

Note: When you create a Window type variable, note that selecting **Browser** as default value supports only Google Chrome tabs whereas selecting **Application** as default value supports any application window.

Use this variable in any number of actions within the automation task. If the application window title changes, then change the value assigned to the variable. The new application title is reflected in all the actions where the variable is used.

Actions in the Window package

The Window package includes the following actions:

Action	Description
Activate	See Activate action in Window on page 3045
Assign	See Assign action in Window on page 3046

Action	Description
Close	See Close action in Window on page 3047
Close all	See Close all action in Window on page 3048
Get active window title	See Get active window title action in Window on page 3048
Maximize	See Maximize action in Window on page 3048
Minimize	See Minimize action in Window on page 3049
Resize	See Resize action in Window on page 3050
Restore	See Restore action in Window on page 3051
Set title	See Set title action in Window on page 3052

[Window package updates](#) on page 919

Review the updates in released versions of packagesuch as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Activate action in Window

The **Activate** action in the Window package enables you to activate a window.

Settings

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.
 - Application:** Select from a list of windows, including browser windows, that are currently open on the Bot Creator device.
 - Browser:** Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- Variable:** Select an existing window variable to specify the title of the application window title.

- In the **Window title** field, specify the title.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `(\w*) -Notepad` for all window title names starting with `(\w*) -Notepad`, or use **Pattern** value as `(\w)\s*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

Assign action in Window

The **Assign** action in the Window package enables you to assign a source window variable's value to a designated window.

Settings

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.
 - **Application:** Select from a list of windows, including browser windows, that are currently open on the device.
 - **Browser:** Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- **Variable:** Select an existing window variable to specify the title of the application window title.
- In the **Select the destination window variable/value** field, specify the variable.

Note: The regular expression (regex) is currently not supported.

Close action in Window

The **Close** action in the Window package enables you to close the application window.

Settings

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.
 - **Application**: Select from a list of windows, including browser windows, that are currently open on the device.
 - **Browser**: Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- **Variable**: Select an existing window variable to specify the title of the application window title.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*)-Notepad)` for all window title names starting with `((\w*)-Notepad)`, or use **Pattern** value as `((\w)\s)*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

Note:

- When multiple Excel windows are opened, the bot closes all the open Microsoft Excel windows even when a specific Excel window name is selected to close.
 - When you select **Currently active** as the window title, to close any active windows, and then run the bot, the **Shut Down Windows** pop-up is no longer activated, even if there are no active windows on the machine.
-

Close all action in Window

The **Close all** action in the Window package enables you to close all the windows.

Settings

In the **Add window** field, you can provide the title of the application windows that you do not want to close.

You can also search the window titles by using (*) as a wildcard character. Specify one or more (*) wildcards at the start, middle, or end of the title. For example, to perform an operation on any window that has Microsoft in the title, use a wildcard to indicate any string by adding it before or after the value: *Microsoft*. The bot first searches for the exact window title (Microsoft), and if it does not find a match, it searches for windows with the term Microsoft anywhere in the title.

Note: To keep the Bot editor window open, ensure that you add it in the **Add window** field. For example, enter *Control Room | Automation Anywhere* in the window title to keep it open.

Get active window title action in Window

The **Get active window title** action in the Window package enables you to retrieve the title of the active window.

Settings

In the **Assign the window title to variable** field, specify the variable.

The shows a descriptive default variable name. If you create several output variables, subsequent variable names are appended with a -1, -2, -3, and so on to avoid duplication.

Note: The regular expression (regex) is currently not supported.

Maximize action in Window

The **Maximize** action in the Window package enables you to maximize a window.

Settings

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.

- **Application:** Select from a list of windows, including browser windows, that are currently open on the device.
- **Browser:** Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- **Variable:** Select an existing window variable to specify the title of the application window title.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*)-Notepad` for all window title names starting with `((\w*)-Notepad`, or use **Pattern** value as `((\w)\s)*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

Minimize action in Window

The **Minimize** action in the Window package enables you to minimize a window.

Settings

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.

- **Application:** Select from a list of windows, including browser windows, that are currently open on the device.
- **Browser:** Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- **Variable:** Select an existing window variable to specify the title of the application window title.

Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.

You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*)-Notepad` for all window title names starting with `((\w*)-Notepad`, or use **Pattern** value as `((\w)\s)*document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

Resize action in Window

The **Resize** action in the Window package enables you to resize a window.

Settings

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.

- **Application:** Select from a list of windows, including browser windows, that are currently open on the device.
- **Browser:** Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- **Variable:** Select an existing window variable to specify the title of the application window title.
- Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.
- You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*) -Notepad` for all window title names starting with `((\w*) -Notepad`, or use **Pattern** value as `((\w) \s) *document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

-
- In the **Left**, **Top**, **Width**, and **Height** fields, specify values for resizing the window.

Restore action in Window

The **Restore** action in the Window package enables you to restore a window.

Settings

- In the **Window** field, select an option: Choose from the **Application**, **Browser**, or **Variable** tab.

- **Application:** Select from a list of windows, including browser windows, that are currently open on the device.
- **Browser:** Select from a list of supported browser tabs.

Note: This option supports , Chromium-based , and browsers.

- **Variable:** Select an existing window variable to specify the title of the application window title.
- Insert a wildcard character (*) in the **Window title** field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has `Microsoft` in the title, use a wildcard to indicate any string by adding it before or after the value: `*Microsoft*`. The first searches for the exact window title (`Microsoft`), and if it does not find a match, it searches for windows with the term `Microsoft` anywhere in the title.
- You can use a regular expression (regex) to identify a window title. Select the regular expression condition as either **String** or a **Pattern** and then enter the value. By default, the **Window title** field is case-sensitive.

To identify a browser title, you can enable the **Case sensitive** option to match the letter case, or disable the option to identify a window title where the letter case does not match.

Note: Ensure that the minimum version installed on your system is the version that was released with v.26. If you have a version released with v.25 or earlier, then by default, the window title will be identified only with matching letter case (case-sensitive).

For example, you can enter the **String** value as `((\w*) -Notepad` for all window title names starting with `((\w*) -Notepad`, or use **Pattern** value as `((\w) \s) *document-Notepad` for only those window titles that match this pattern.

Note:

- When you use a regular expression of type **String** with `-title` as the input value for a window title in any , the might encounter a run time error. To prevent the run time error, ensure that when you add the string input as `*-title`, the application with the specific title is open. The asterisk (*) is just a character, not a wild card character.
- When you use a regular expression of type **Pattern** with `-title` as the input value for a window title in any , the might encounter a run time error because the input value `*-title` is incorrect.

Ensure that you use valid regex patterns.

Set title action in Window

The **Set title** action in the Window package assign a new window title to a window variable.

Settings

- In the **Window** field, click one of the following tabs:
 - **Browser**

- Click the **Choose a browser tab** drop-down menu to select any of the active browsers on your system. Google Chrome, Chromium-based Microsoft Edge, and Internet Explorer browsers are supported.

(Optional) Click the **Refresh windows** icon to update the list.

- In the **Browser title** field, click one of the following tabs:
 - **String**: Enter a wildcard character (*) in the window title field to search for window titles that can change. You can specify one or more wildcards (*) at the start, middle, or end of the value. For example, to perform an operation on any window that has Microsoft in the title, use a wildcard to indicate any string by adding it before or after the value: *Microsoft*. The bot first searches for the exact window title (Microsoft), and if it does not find a match, it searches for windows with the term Microsoft anywhere in the title.
 - **Regex**: You can use a regular expression (regex) to identify a window title. Select the regular expression **Type** as either **String** or **Pattern** and then enter the value. By default, the Window title field is case-sensitive.

For example, you can enter the **String** value as `((\w*)-Notepad` for all window title names starting with `((\w*)-Notepad`, or use **Pattern** value as `((\w)\s)*document-Notepad` for only those window titles that match this pattern.

- The **Case sensitive** option is enabled by default and is used to match the letter case. Optionally, you can clear the check box to identify a window title where the letter case does not match.

Note: Ensure that the minimum Bot Agent version installed on your system is the version that was released with Automation 360Automation 360 v.26. If you have any of the older Bot Agent versions, the window title will be identified only with matching letter case (case-sensitive) by default.

- The **Link to the web page** field displays the address of the website you have selected through the browser.
- The **Browser application** field displays the name of the browser you have selected.

- **Application**

Click the **Choose an application window** drop-down menu to select an application that is currently active on your Bot Creator device.

(Optional) Click the **Refresh windows** icon to update the list.

- **Variable**

Select an existing application window or browser tab to specify the title.

- In the **Window title is** field, select one of the following options for new title:
 - **Not a regular expression**: If the sub-string is not a regular expression.
 - **A regular expression**: If the sub-string is a regular expression.
- In the **New window title** field, enter the new title that you want to assign.

(Optional) Click the **Insert a value** icon to select an existing variable for the new title.

Workload package

The Workload package enables you to insert work items in a queue for workload automation. It also enables data chaining between multiple queues. You can orchestrate multiple bots, and enable optimal device utilization through the queueing mechanism of workload management.

For example, a business process of Employee Salary Processing:

- A payroll queue can process the employee salaries, and a payroll bot can add work items to a finance queue.
- The finance queue in turn can release the funds to employees and a finance bot in turn adds works items in a HR queue to email employees on the salary processing completion.

You must have the Queue **Owner** or **Participant** privileges to view the list of queues in the Workload package.

Actions in the Workload package

The Workload package includes the following action:

Note: If you built a bot using actions from the Workload package from Build 5322 or earlier, the action will be missing when you open the bot with the default package version. You must reinsert the action and repopulate the fields.

Action	Description
Insert work item	Allows you to insert a work item from an existing queue to another queue as part of a bot execution.

Related concepts

[Workload management](#) on page 1931

The workload management module enables users to upload Microsoft Excel and CSV files to the Control Room so that it feeds the records from the files into the bot deployments.

Related tasks

[Attach work item template to bot](#) on page 2224

Attach a work item template to a bot to use the bot in workload automation.

[Use Work Item variables](#) on page 2253

You can use the Work Item variables to pass the Work Item attributes or values to the Task Bot from the Control Room when you run the bot with the option **Run bot with queue**.

Using Insert work item action

The **Insert work item** action provides you the flexibility to insert a work item to another queue as part of a bot execution.

- You must have the Queue **Owner** or **Participant** privileges to view the list of queues in the Workload package.

- Do not attach the bot with a work item template as the bot fails when it is deployed on a Bot Runner.
- The maximum number of characters you can insert in a work item value is 1000.

Considerations when using the **Insert work item** action:

- Run the bot using one of the following options:
 - Run bot now
 - Schedule bot
 - Run with triggers
- Use the **Insert work item** to manage complex workflows by configuring a bot to add work items from multiple queues.

For example, use a bot to read a list of invoices from a .csv file and add the invoices due for payment to another bot that manages information of payments due on specific dates. The automation can be used in the scenarios where work items are part of a different system (Database, Excel) and the bot reads them and adds them to a queue or where one queue adds work items to another queue as part of data chaining.

1. In the **Automation** page, **Create** a bot or **Edit** an existing bot.
2. In the **Actions** palette, double-click or drag the **Insert Work Item** action from the Workload package.
3. In the **Workload: Insert work item** window, add parameters such as the **Queue** and work item values:
 - a) Click **Browse** to select a queue name from the list of queues to insert as a work item.
 - b) Click **Confirm** to add the queue.
 - c) Start entering work item values in the work item fields.

Note: These parameters are populated based on the work item template associated with the selected queue.

You can also assign a variable value to these parameters by pressing the F2 key and selecting a variable name from the list.

Tip: Use UTC format (YYYY-mm-dd 00:00:00) for **Date** data type.

4. Click **Save**.
The action is added to the bot.
5. Add more data using the **Insert Work Item** action.
After the required data is added, **Save** the bot and **Check in** the bot to the **Public** folder for further processing and deployment.

Related concepts

[Create workload queues](#) on page 1932

A queue is one of the main building blocks of Workload Management. A queue holds data known as Work Items for further processing. The system distributes these Work Items to individual unattended Bot Runners in a device pool for processing.

Related tasks

[Attach work item template to bot](#) on page 2224

Attach a work item template to a bot to use the bot in workload automation.

[Use Work Item variables](#) on page 2253

You can use the Work Item variables to pass the Work Item attributes or values to the Task Bot from the Control Room when you run the bot with the option **Run bot with queue**.

[Insert Work Items](#) on page 1939

Add Work Items from a CSV file to the queue after you define the structure.

XML package

Extensible Markup Language (XML) is a markup language designed to store and transport data. Use the actions in the XML package to automate the processing of XML data generated from web services and cloud computing applications.

An XML document is structured as an ordered and labeled tree. Each node of the tree is an XML element and is written with an opening and closing tag. In the following example, custname and custid are nodes:

```
<customer>
<custname>XYZ Corp</custname>
<custid>A001</custid>
</customer>
```

XPath is a query language that uses path expressions to select nodes or node-sets in an XML document. XPath includes built-in functions for manipulation of string, numeric, Boolean, date and time, and so on.

Before you start

Perform the following actions within the XML package.

1. Start the XML session using the **Start XML Session** action. Use this session name for all corresponding actions.
2. Use the different actions available in the XML package to automate XML-related tasks.
3. Save the session using the **Save XML Session** action to assign the data to a file or String-type variable.
4. End the session using the **End XML Session** action to complete a task.

Actions in the XML package

The XML includes the following actions:

Action	Description
Delete node	See Delete node action in XML on page 3057.
End session	See End session action in XML on page 3057.
Execute XPath function	See Execute XPath function action in XML on page 3058.

Action	Description
Get multiple nodes	See Get multiple nodes action in XML on page 3058.
Get single node	See Get single node action in XML on page 3059.
Insert node	See Using Insert node action on page 3060.
Save session data	See Save session data action in XML on page 3061.
Start session	See Start session action in XML on page 3061.
Update node	See Update node action in XML on page 3062.
Validate XML document	See Validate XML document action in XML on page 3062.

Related reference

[XML package updates](#) on page 921

Review the updates in released versions of the XML package such as new and enhanced features as well as fixes and limitations. The page also lists the release dates of each version, and the compatible Control Room and Bot Agent versions.

Delete node action in XML

The **Delete node** action in the XML package enables you to delete a specific node from XML file.

Settings

- Enter the **session name** or select an existing variable used in the **Start XML session** action.
- Enter the **XPath expression** for the node to be deleted.
- Enter the **attribute** (optional).

End session action in XML

The **End session** action in the XML package enables you to close an XML session.

Settings

Enter the **session name** or select an existing variable used in the **Start XML session** action .

Note: The **End session** action clears out session-related data from memory. To save the modified data, use the **Save session data** action.

Execute XPath function action in XML

The **Execute XPath function** action in the XML package enables you to execute XPath function and store the results in a variable.

Settings

- Enter the **session name** or select an existing variable used in the **Start XML session** action.
- Enter the **XPath expression** or select an existing variable.
- Assign a **String-type variable** to the output.

For more information on how to use some of the actions (including Execute XPath function), see this example topic [Example for using actions in XML package](#) on page 3063.

Get multiple nodes action in XML

The **Get multiple nodes** action in the XML package enables you to retrieve the value of multiple nodes.

Settings

- Enter the **session name** or select an existing variable used in the **Start XML session** action.
- Enter the **XPath expression** to retrieve multiple nodes or select an existing variable.
- In the Get each node field, select if you require the **Text value**, **XPath expression**, or **Specific attribute name of each node**.
 - Text value retrieves the exact value of the specific node element.
 - XPath expression refers to the path of the selected node in an XML document.
 - Specific attribute defines a property or the type of the element in a particular node. For example, `lang` is an attribute of the `Locale` element in a `Cust_Details` node. The output for `lang` attribute is displayed as `es`.

Example of how to retrieve the value of multiple nodes

You can create an XML file on your desktop. This example uses a sample XML with the following structure:

```
<Customer>
<Cust_Details>
  <custid city="Leon">A001</ custid>
  <custname>XYZ Corp</custname>
  <custzipcode>15639</custzipcode>
  <country>Mexico</country>
  <Locale lang="es"> Spanish</Locale>
</Cust_Details>
</Customer>
```

To retrieve the value of multiple nodes from a customer details:

1. Create and name the bot: XML_Bot.
2. Start an XML session by using the **XML > Start session** action.
 - a) In the **Session name** field, enter Default.
 - b) In the **Data Source** field, choose **File** and select the **Desktop file** option. Click **Browse** to locate your XML file, for example: D:\userdefined path\xml sample.xml.
3. Double-click or drag the **Get multiple nodes** action to retrieve the value of multiple nodes.
 - a) In the **Session name** field, enter Default.
 - b) In the XPath Expression field enter //Customer/Cust_Details/custid.
 - c) In the **Get each node** field, select from the following options and print the output in the message box.
 - **Text value**
 - **XPath expression**
 - **Specific attribute name of each node**, If you select this option then enter the attribute city in the text box.
 - d) In the **Assign the output to variable (optional)** field, select TableXMLNodes.
4. Double-click or drag the **Message box** to print the values and enter \$TableXMLNodes [0] [0]\$ in the **Enter the message to display** field.
5. Click **Save** and then click **Run**.

The values retrieved from each node are as follows:

- **Text value:** A001
- **XPath expression:** /Customer/Cust_Details/custid
- **Specific attribute name of each node:** Leon

Get single node action in XML

The **Get single node** action in the XML package enables you to retrieve the value of a single node.

Settings

- Enter the **session name** or select an existing variable used in the **Start XML session** action.
- Enter the **XPath expression**, and **attribute** (optional) to retrieve a node.

Get single node retrieves the first value from the XML document based on the provided XPath expression and the attribute. For example,

```
<Customer>
<Cust_Details>
  <custid>A001</ custid>
  <custname>XYZ Corp</custname>
  <custzipcode>15639</custzipcode>
  <country>Mexico</country>
```

```
<Locale lang="es"> Spanish</Locale>
</Cust_Details>
</Customer>
```

- XPath expression with attribute: The attribute value of the XPath expression element is displayed. For example, if the XPath expression is entered as `Customer//Cust_Details//Locale` with the attribute as `lang`, the output is displayed as `es`.
 - XPath expression without attribute: The value of the XPath expression element is displayed. For example, if the XPath expression is entered as `Customer//Cust_Details//Locale` without any attribute, `Spanish` is displayed as an output.
- Assign the output to a **String-type variable**.

Using Insert node action

Use this action to insert a node in an existing XML file and assign it to a value. Optionally, assign a name space and attributes to the node.

Note: When you use the Insert node action, the attributes are alphabetically sorted and displayed in the XML output.

To insert a node, do the following:

1. Enter the session name.
Use the name of the session that you have used in the **Start XML session** action.
2. Specify an **XPath expression** to indicate where to insert the new node.
3. Enter a node name.
4. Enter a value for the node.
5. If the node name exists, select from the following options:
 - **Insert it anyways**
 - **Skip it**
 - **Overwrite it**
6. Specify the location to insert the node from the following options:
 - **Beginning of the child nodes**
 - **End of the child nodes**
 - **Before specific child note**
 - **After specific child node**

If **Before Specific child node** or **After Specific child node** is selected, specify the child node name before or after which the node must be inserted.

7. Optional: Enter the default name space to be mapped to the node.
8. Enter the attributes using a Dictionary-type variable.
Create a new variable of type **Dictionary** or use one that already exists.
9. Optional: Enter the attribute name space using a Dictionary-type variable
Create a new Dictionary-type variable or use one that already exists.
10. Click **Save**.

Save session data action in XML

The **Save session data** action in the XML package enables you to save the XML session data to a file or variable of type String.

Settings

- Enter the **session name** or select an existing variable used in the **Start XML session** action.
- To save the session data to a file, select the **Write XML data** option and specify a **file path**.
- Select **Overwrite** to replace the existing file if a file with the same name exists in the location you have specified.
- Select the **Use Prettyprint** check box to format your code with proper indentation as per Prettyprint.

Note: By default, it uses a 2-space indentation and does not add XML document declaration explicitly.

Use Prettyprint feature works effectively when:

- The source XML document supports the linearization of a tree structure.
- You select the **Remove text nodes that contain only white space** check box in the **Start session** action.

Note:

- If the source document is already formatted, you do not have to select the **Use Prettyprint** check box.
- When you migrate bots from Enterprise 11 to Automation 360 that are using the **Save session data** action, the **Use Prettyprint** check box is selected by default.

-
- Assign the output to a **String-type variable**.

Note: The session data will be saved if you select the **Write XML data** option.

Start session action in XML

The **Start session** action in the XML package enables you to create a new XML session based on an XML file or specified text.

Settings

- Start the XML session.
- Enter the **session name** or select an existing variable used in the **Start XML session** action. Use this **session name** for all corresponding actions.
- In the Data Source field, select either **File** or **Text**:
 - File: Select from the **Control Room file**, **Desktop file**, or an existing **Variable** of File type.
 - Text: Specify the text name or select an existing variable.

- Select the **Remove text nodes that contain only white space** check box to remove the blank text nodes when you parse the XML document.

Note: When you migrate bots from Enterprise 11 to Automation 360 that are using the **Start session** action, the **Remove text nodes that contain only white space** check box is selected by default.

- Save the XML session.

Update node action in XML

The **Update node** action in the XML package enables you to update the value of a node.

Note: When you use the Update node action, the attributes are alphabetically sorted and displayed in the XML output.

Settings

- Type the **session name** or select an existing variable used in the **Start XML session** action.
- Enter the **XPath expression** for the node to be updated.
- Enter a **New value** for the node.
- Select the **Updates attribute (s)** option to create a new **Dictionary** or to add an existing **Variable** of Dictionary-type.

Validate XML document action in XML

The tags and document structure are defined when the XML document is created. Use the **Validate XML document** action in the XML package to validate an XML document.

Settings

- Enter the **session name** or select an existing variable used in the **Start XML session** action.
- Select the validation type from the following options:
 - **XML schema files (.xsd)**
 - **List:** Specify the schema XSD file path you want to validate in the **Value** field. Click **Add** to add multiple XML schema files (.xsd).
 - **Variables:** Create a new variable of type **List** with subtype **String** and enter the XSD file path in the **Default value field (optional)** or use an existing variable.
 - **Internal Document Type Definitions (DTDs)**
 - **Well formed**
- Assign the output to a variable using **Assign the output (Valid or Invalid) to variable**

Example for using actions in XML package

Using the XML package, create a bot that reads and writes data from an XML file to an Excel sheet.

The sample XML used in this tutorial has the following structure:

```
<movies>
  <movie genre="" year="">
    <name></name>
    <description></description>
    <director></director>
    <writers>
      <writer type=""></writer>
      <writer type=""></writer>
    </writers>
    <rating>R</rating>
  </movie>
</movies>
```

Before you begin, [download a sample XML file](#).

The tutorial is intended to demonstrate the following actions:

- Use an XPath expression to get a node set with specific value and iterate through the items in the node set, for example, movies with specific rating in this tutorial.
- Use an XPath function to iterate through the child node sets.
- Concatenate variables to build a string.
- Write data to an Excel sheet.

Ensure the following:

- You know how to create bots.
- You are familiar with the Control Room user interface.

1. Create a bot and name it XMLDataReader.
2. Add a step to group all tasks for opening an Excel sheet.
 - a) Add the **Step > Step** action after the **Start** flow in the Bot editor.

Note: To add an action, search for the action in the **Actions** pane and drag it to the bot flow in the Bot editor.

 - b) In **Title**, enter `Open an Excel Sheet` and save the action.
3. To create and open an Excel sheet, use **Excel advanced > Create workbook**.
 - a) Add the **Excel advanced > Create workbook** action within the **Step** action.
 - b) In **File path**, enter `C:\movies\movies.xlsx`, and save the action. If the `movies` folder does not exist in the specified path, create a `movies` folder in the path.
4. To select the first cell on the Excel sheet, use the **Excel advanced > Go to cell** action.
 - a) Add the **Excel advanced > Go to cell** action after the **Excel advanced: Create workbook** action.
 - b) Click **Specific cell** if it is not already selected, and enter `A1`.

- c) Save the action.

5. Create another step to group all the tasks for retrieving XML data.
 - a) Add the **Step > Step** action after the first **Step** action.
 - b) In **Title**, enter `Get XML Data` and save the action.

6. Start an XML session.
 - a) Add the **XML > Start session** action within the **Get XML Data** step.
 - b) Under **File**, select **Desktop**, browse and select the sample XML file that you downloaded.
 - c) Save the changes.

7. To get all movie nodes with rating R, use the **Get multiple nodes** action.
 - a) Add the **XML > Get multiple nodes** action after the **Start session** action.
 - b) In **XPath Expression**, enter `//movie[rating/text()='R']`, and save the action. The selected node set is stored in a system variable and is available to the **For each Node in a XML dataset** iterator now.
 - c) To ensure that the action retrieves the entire node set instead of just the text nodes, click **Xpath expression**.

8. Use the **Loop** action to iterate through the selected node set that the **Get multiple nodes** action retrieves.
 - a) Add **Loop > Loop** after the **XML: Get multiple nodes** action.
 - b) Under **Iterator**, select **XML > For each Node in a XML dataset** as the iterator.
 - c) In **Assign the current row to this variable**, click **(x)** and create a variable with the default name, for example, XMLNode. Each item in the node set is now available through the variable.
 - d) Save the action.

9. To get the movie name from the iterated node, use the **Get single node** action.
 - a) Add the **XML > Get single node** action within the **Loop: Loop** action.
 - b) In **XPath expression**, enter `$XMLNode$/name`.
 - c) In **Assign the output to variable**, create a variable and name it `sMovieName`.
 - d) Save the action.

10. To write the movie name from the XMLNode variable, use the **Set cell** action.
 - a) Add the **Excel advanced > Set cell** action after the **Get single node** action.
 - b) Click **Active cell**, enter `$sMovieName$` in **Cell value**, and save the action.

11. To select a new cell within the Excel sheet, use the **Go to cell** action.
 - a) Add the **Go to cell** action after the **Set cell** action after the **Excel advanced: Set cell** action.

- b) Click **Active cell**, select **One cell to the right**, and then save the action.
12. To get the director name from the iterated node, use the **Get single node** action.
- Add the **XML > Get single node** action after the **Excel advanced: Go to cell** action.
 - In **XPath expression**, enter `$XMLNode$/director`.
 - In **Assign the output to variable**, create a variable with the following name: `sDirector`
 - Save the action.
13. To write the director name from the XMLNode variable, use the **Set cell** action.
- Add the **Excel advanced > Set cell** action after the **XML: Get single node** action.
 - Click **Active cell**, enter `$$$sDirector$` in **Cell value**, and save the action.
14. To select a new cell within the Excel sheet, use the **Go to cell** action.
- Add the **Go to cell** action after the **Excel advanced: Set cell** action.
 - Click **Active cell**, select **One cell to the right**, and then save the action.
15. Because the `<writers>` node can contain multiple `<writer>` nodes, get each writer name, concatenate the names, and write them to a single cell instead of writing values to multiple cells. To do so, add the **Loop** action within the current **Loop** action.
- To get the number of the `<writer>` nodes within the `<writers>` node, add the **XML > Execute XPath function** after the **Excel advanced: Set cell** action. In **XPath expression**, enter `count ($XMLNode$/writers/writer)`. In **Assign the output to variable**, create a variable named `sWriterCount`.
You will use the `<writer>` node count to loop through all the `<writer>` nodes.
 - Add the **Loop > Loop** action after the **XML: Execute XPath function** action.
-
- Important:** The second **Loop** action must be added within the main **Loop** action.
-
- Under **Iterator**, select **For n times** as the iterator.
 - In **Times**, enter the following: `$$$sWriterCount$.String:toNumber$`
-
- Note:** `sWriterCount` contains a string value. To convert string to number, you can use the `$(variable name).String:toNumber$` format, for example, `$$$sWriterCount$.String:toNumber$`.
-
- In **Assign the current value to variable (optional)**, create a variable named `Counter`.
 - Save the action.
16. To concatenate the values from all writer nodes, create a string variable.
- In the **Variables** pane, click the plus icon.
The **Create variable** window opens.
 - In **Type**, select **String**.
 - In **Name**, enter `sWriters`.

d) Click **Create**.

17. To get the value from the iterated <writer> node, use the **Get single node** action.

a) Add the **XML > Get single node** action within the second **Loop** action.

b) In **XPath expression**, enter `$XMLNode$/writers/writer[$Counter.Number:toString$]`.

Using the Counter variable, you can access a node at a specific index. Note that because the Counter variable contains a numeric value, the `.Number:toString$` expression is added to the Counter variable to convert it to a string.

c) In **Assign the output to variable**, create a variable and name it `sWriter`.

d) Save the action.

18. To assign values from the writer nodes, use the **String > Assign** action.

a) Add **String > Assign** action after the **XML: Get single node** within the second loop.

b) In **Select the source string variable(s)/ value (optional)**, enter `$sWriters$, $sWriter$`.

c) In **Select the destination string variable**, select `sWriters`.

d) Save the action.

After the inner loop is complete, the `sWriters` variable will contain all the writer names.

19. To write the writer names to a new cell, use the **Excel advanced > Set cell** action within the main loop.

a) Add the **Excel advanced > Set cell** action after the inner **Loop** action within the first **Loop** action.

b) Click **Active cell**.

c) Enter `$sWriters$` in **Cell value**.

d) Save the action.

The data retrieved from one <movie> node is written to a row. To write the data from the next <movie> node, you must select the next row in the Excel sheet.

20. To move the cursor to the next row, use the **Excel advanced > Go to cell** action.

a) Add the **Go to cell** action after the **Set cell** action.

b) Click **Active cell**, select **Beginning of the row**, and then save the action.

c) Add the **Go to cell** action again. Click **Active cell**, select **One cell below**, and then save the action.

21. Before the next node in the retrieved <movie> node set is iterated, you must reset the `sWriters` variable. To reset the `sWriters` variable, perform the following steps:

a) Add the **String > Assign** action after the **Excel advanced: Go to cell** within the main loop.

b) Leave **Select the source string variable(s)/ value (optional)** blank.

- c) In **Select the destination string variable**, select sWriters.
 - d) Save the action.

- 22. Create a new step.
 - a) Add the **Step > Step** action after the second **Step** action.
 - b) In **Title**, enter `Close the file`.

- 23. To close the Excel sheet, use **Excel advanced Close** action.
 - a) Add **Excel advanced > Close** within the **Close the file** step.
 - b) Save the changes.

- 24. Run the bot.

Get started building bots

Use the following three examples to become familiar with building bots using in the cloud-based Bot editor. These examples demonstrate using actions and the Universal Recorder to automate tasks in applications and browsers.

[Build a Go be Great bot](#) on page 3068

Build a basic bot using a **Message Box** action and a variable. Follow these steps to create your first bot that prints the message, `Go be great!`, the Automation Anywhere version of `Hello World!`

[Build a basic bot that uses a desktop application](#) on page 3069

Build a bot that uses a conditional statement to verify that the calculator is open, then uses the calculator to multiply two numbers. This example uses actions from the Application, If, Simulate keystrokes, Message Box, and Window packages.

[Example of extracting data from a web table](#) on page 3071

Build a bot to open a browser window to the Wikipedia website, extract the data from a table, and write it to a CSV file on your desktop. This example uses actions from the Browser, Data Table, Recorder, and Window packages.

For more examples, see [Examples of building bots](#) on page 3072.

More resources

- To learn more, search for the Hello Automation 360 Bot: Getting Started with Building Bots course in [Automation Anywhere University: RPA Training and Certification \(A-People login required\)](#).

- You can also visit the [Learn section of the developer portal](#) for more guidance. Find learning journeys and videos for both new and experienced developers on how to build your first bots.

Build a Go be Great bot

Build a basic bot using a **Message Box** action and a variable. Follow these steps to create your first bot that prints the message, `Go be great!`, the Automation Anywhere version of `Hello World!`

To build a bot you must already have done the following:

- [Install Bot Agent and register device](#) on page 1288
- [Set user device credentials](#) on page 1295

If you have already completed the steps in [Create your first bot](#) on page 1429, skip to Step 6.

1. Create a new bot:
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Bot**.
 - c) In the **Create Task Bot** window, enter the bot name.
 - d) Accept the default folder location: `\Bots\`
To change the default bot storage location, click **Choose** and follow the prompts.
 - e) Click **Create and edit**.
2. Insert a **Message box** action.
 - a) Click **Actions**.
 - b) Search for the Message Box package.
Click in the **Actions** search box and enter `message`. Click the arrow to expand the Message Box options.
 - c) Double-click or drag the **Message box** action to the Bot editor (open space to the right).
3. In the dialog box on the right, specify the conditions for the **Message box** action.
 - a) In the **Enter the message box window title** field, enter `My first bot!`.
 - b) In the **Enter the message to display** field, enter `Go be great!`.
 - c) Accept the defaults in the **Scrollbar after lines** field and **Close message box after** check box.

4. Click **Save**.

Your bot is now ready to run.

You can view the time spent to create a bot by navigating to **Automation > Home > My metrics**. The **Active Task Bots** table displays the time taken to create every bot. When a bot is edited, the table shows the total time spent on the bot.

For example, if you spend 10 minutes on creating and saving a bot, the **Active Task Bots** table displays the time spent as 10 minutes. If you spend 5 more minutes on editing the same bot, the **Active Task Bots** table displays the total time spent as 15 minutes.

Similarly, the **Average time spent to create a Task Bot** field on the **My Metrics** page displays the average time spent across all users on all bots.

For example, if user 1 spends 120 minutes on **Bot A**, user 2 spends 2 minutes on **Bot B**, and user 3 spends 4 minutes on **Bot C**, the average time is calculated as $(120+2+4)/3 = 42$ minutes.

5. Test your bot.

Click **Run** at the top right.

The bot displays a Message box with the text `Go be great!`.

In the following steps, you configure a variable and insert it in the Message box.

6. Create a variable.

- a) Click **Variables** from the accordion menu on the left panel.
- b) Click **Create variable** (the + sign).
- c) Enter `vHelloWorld` in the name field.
- d) Select the **Use as output** option.
- e) Enter `Say Go be Great! with a variable` in the **Default value** field.
- f) Click **Create**.

7. Assign the `vHelloWorld` variable to the **Enter the message to display** field.

- a) Click the **Message box** action in the Bot editor.
- b) In the dialog box, delete the text from the **Enter the message to display** field.
- c) Either press the F2 key or click the **Insert variable** icon.
The **Insert variable** icon is located on the right-side of the text field.
- d) Select `vHelloWorld` from the drop-down list.
- e) Click **Yes, insert**.

8. Click **Save**.

9. Click **Run**.

The bot displays a Message box with the text `Say Go be Great! with a variable`.

After you successfully run your bot, go to [Build a basic bot that uses a desktop application](#) on page 3069.

Build a basic bot that uses a desktop application

Build a bot that uses a conditional statement to verify that the calculator is open, then uses the calculator to multiply two numbers. This example uses actions from the Application, If, Simulate keystrokes, Message Box, and Window packages.

To build a bot you must already have done the following:

- [Install Bot Agent and register device](#) on page 1288
- [Set user device credentials](#) on page 1295

1. Open a new bot.

- a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.

- b) Click **Create new > Bot**.
 - c) Enter a bot name and click **Create and edit**.
2. Insert an conditional sequence that verifies that the calculator is open and activates the window.
- a) Double-click or drag the **If** action.
 - b) Select **Window exists** from the **Condition** drop-down list.
 - c) Select the **Application** tab and click the refresh icon to display all open applications.
 - d) Select **Calculator** from the **Window** drop-down list.
The Calculator window is saved to the variable `window-1`.
 - e) Drag the **Message box** action into the **If** container.
 - f) In the **Enter the message to display** field, enter `The calculator is running`.
 - g) Drag the **Window > Activate** action into the **If** container below the **Message box** action.
 - h) In the **Window** field, insert the `window-1` variable.
3. Insert an alternative sequence that opens the calculator.
- a) Double-click the **If > Else** action.
 - b) Drag the **Message box** action into the **Else** container.
 - c) In the **Enter the message to display** field, enter `The calculator is not running`.
 - d) Drag the **Application > Open program/file** action into the **If** container below the **Message box** action.
 - e) In the **Location of the program/file** field, enter `C:\Windows\System32\calc.exe`.
4. Insert the **Simulate keystrokes** action to perform the calculation.
- a) Drag the **Simulate keystrokes** action below the **If** and **Else** containers.
 - b) In the **Window** field, insert the `window-1` variable.
 - c) In the **Keystrokes** field, enter `5*5=`.
 - d) In the **Delay** field, enter 500.
5. Click **Save** to save the bot.
6. Run the bot.
When the bot runs, the `The calculator is not running` message appears, then the Calculator window opens, and the calculation is performed.
7. Run the bot again.
When the bot runs, the `The calculator is running` message appears, then the Calculator window activates, and the calculation is performed.

If the bot does not input all of the numbers into the calculator, try increasing the keystrokes delay.

Example of extracting data from a web table

Build a bot to open a browser window to the Wikipedia website, extract the data from a table, and write it to a CSV file on your desktop. This example uses actions from the Browser, Data Table, Recorder, and Window packages.

To extract data from a table, do the following steps:

1. Create a new bot:
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Bot**.
 - c) In the **Create Task Bot** window, enter the bot name.
 - d) Accept the default folder location: `\Bots\`
To change the default bot storage location, click **Choose** and follow the prompts.
 - e) Click **Create and edit**.

For information about bot naming conventions, see [Create your first bot](#) on page 1429.

2. Open a browser window to the web page from which you will extract the table.
 - a) Double-click or drag the **Browser > Open** action.
 - b) Select your preferred browser.
 - c) In the `Link to open` field, enter `https://en.wikipedia.org/wiki/Table_(information)`.
 - d) Click **Save**.
 - e) Click **Run**.
The bot opens the window.
3. Specify the table.
 - a) Double-click or drag the **Recorder > Capture** action.
 - b) From the far-right panel, in the **Window** options, select the **Browser** tab and then select the **Table (information) - Wikipedia** window from the drop-down list.
If the window title does not appear in the list, click **Refresh**.
 - c) Click **Capture object**.
The **Table (information) - Wikipedia** window activates.
 - d) Hover over the Age table below the Basic description heading.
An orange box appears, surrounding the table.
 - e) Click the table.
The **Object Processing** message box appears.
 - f) Return to the Control Room.
 - g) In the Object properties table, verify the Control Type is TABLE.
If it is not, click **Recapture object**.
 - h) From the Action to take on object drop-down list, select **Get table**.
 - i) In the **Save the outcome to a variable** field, create the `Tabledata` variable.

The **Table (information) - Wikipedia** window is saved as the variable \$Browser1\$.

4. Specify the file where to save the data.
 - a) Double-click or drag the **Data Table > Write to file** action.
 - b) From the **Data table name** list, select Table1data.
 - c) In the **Enter file name** field, select your file.
For example, C:\Users\\Desktop\WikipediaTable.csv.
 - d) Select to overwrite the existing file.
5. Close the **Table (information) - Wikipedia** window.
 - a) Double-click or drag the **Browser > Close** action.
 - b) Select the **Variable** tab and insert \$Browser1\$.
6. Click **Save**.
7. Click **Run**.

The bot creates a CSV file on the desktop with data on seven indexes, their values, and net change.

Examples of building bots

Use these example tasks to become familiar with the features and learn to build bots in Automation 360.

Common automation tasks and examples

This document lists common automation tasks and examples for the tasks.

Spreadsheet operations

Task	Subtasks/approaches	Example
Read data from spreadsheets	If the spreadsheet is large, you can connect to it as a database.	Connect to an Excel spreadsheet as database
	Read individual rows.	Example of transferring data from CSV file to Excel worksheet on page 3083
	Read data from an Excel spreadsheet and store it in a data table variable.	Example of reading data from a spreadsheet on page 3092
	Read data from spreadsheets and write to a database.	Example of migrating data from Excel to a database on page 3088

Task	Subtasks/approaches	Example
Write to spreadsheets	Create a new spreadsheet and write data to it.	Example of reading data from a spreadsheet on page 3092
Merge spreadsheets	Merge two spreadsheets	Run TaskBot to merge Excel sheets on page 3087

SAP operations

Task	Subtasks/approaches	Examples
Call SAP BAPI functions	Get structure.	Example of using Get structure command from SAP BAPI package on page 3101 Example of using Run standard workflow from SAP BAPI package on page 3105
	Write data to SAP using SAP BAPI.	Example of writing data to SAP using SAP BAPI package on page 3103

Variables, control flow, and logic operations

Task	Subtasks/approaches	Examples
Variables	Pass values between bots.	Example of passing a value between bots on page 3076
	Use file variables.	Example of using a file variable on page 3137
	Use dictionary variables.	Create dictionary type variables on page 3141
Conditions	Use String condition.	Example of using a conditional statement on page 3078

Custom scripts integration in bots

Tasks	Subtasks/approaches	Example
Use custom Python scripts.	Invoke Python function in bots.	Build a hello world with a Python function

Tasks	Subtasks/approaches	Example
		Example of using Python script to join a list on page 3079
Use custom VBScript.	Invoke a VBScript function.	Example of using the VBScript package in a resilient bot on page 3107

Example of entering data into a web form from a spreadsheet

Build a bot that reads multiple rows of data from an XLSX sheet and enters it into a web form. Use actions from the Excel advanced, Loop, and Recorder packages to build the bot.

Before you start building the bot, you can create the following data sets on your desktop in `.xlsx` format as below.

Employee name	Age	Claim amount	Claim date	Claim type
Mike	30	469	22/3/2022	Medical
Sarah	34	766	28/3/2022	Dental
Chris	41	428	13/05/2022	Medical
Samantha	45	1000	09/05/2022	Medical

To read values from an Excel file and input them into a web form, do the following:

1. Create a new bot:
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Bot**.
 - c) In the **Create Task Bot** window, enter the bot name.
 - d) Accept the default folder location: `\Bots\`
To change the default bot storage location, click **Choose** and follow the prompts.
 - e) Click **Create and edit**.
2. Open the Excel file.
 - a) Double-click or drag the **Excel advanced > Open** action.
 - b) Enter a session name.
 - c) Select the Excel file.
 - d) Mark the **Sheet contains a header** option.

By marking the **Sheet contains a header** option, you enable the bot to search for the column by the header name during run time.

3. Launch the website.
 - a) Double-click or drag the **Browser > Open** action.

- b) Enter the website URL which consists the webform to update the data.
4. Retrieve the worksheet values and store them in a Table variable.
 - a) Double-click or drag the **Excel advanced > Get multiple cells** action.
 - b) Enter the same session name you used in the **Excel advanced > Open** action.
 - c) Select **All rows** from the drop-down list.
 - d) Create a Table variable using the icon to the right of the **Assign to variable** drop-down list.
 5. Instruct the bot to process the data row by row.
 - a) Double-click or drag the **Loop** action.
 - b) Select the **For each row in table** iterator.
 - c) Select the same Table variable that you used in **Get multiple cells**.
 - d) Create a Record variable using the icon to the right of the **Assign to variable** drop-down list.

The Record variable holds all of the values for one row. With each iteration of the Loop, the bot retrieves the values of the next row and stores them in the Record variable, overwriting the values from the previous row.

6. Map the first column header to the web form textbox.
 - a) Double-click or drag the **Recorder > Capture** action.
 - b) Select the same window you opened with the **Open** action.
 - c) Click **Capture object**.
 - d) Hover over the textbox until a red outline appears.
 - e) Click the textbox.
 - f) Return to the Control Room.
 - g) Verify that the **Control Type** value is TEXTBOX.
 - h) Select **Set text** from the **Action** drop-down list.
 - i) In the **Keystrokes** field, insert the same Record variable that you used in the Loop.
 - j) Select the **By name** option and copy-paste the first column header into the field.
7. Repeat the sub-steps in step 5 to map the other columns, with the following differences:
 - a) Instead of searching for the browser window title, insert the Window variable generated by the Recorder.
 - b) When inserting the Record variable in the **Keystrokes** field, copy-paste the subsequent column header into the "By name" field.
8. Capture the Submit button.
 - a) Double-click or drag the **Recorder > Capture** action.
 - b) Insert the Window variable generated by the Recorder.
 - c) Click **Capture object**.
 - d) Verify that the **Control Type** value is BUTTON.

- e) Select the **Click** action.

9. Click **Save**.

Related reference

[Excel advanced package](#) on page 2479

The Excel advanced package contains actions that enable you to automate many of the repetitive tasks when working with Microsoft Excel spreadsheets.

[Loop package](#) on page 2679

Use the Loop package to run a sequence of actions repeatedly for a specific number of times or until a specific condition is met.

[Recorder package](#) on page 2798

Recorder package captures a series of tasks in a process and then automates them. You can automate your business applications (for example, desktop, Web, SAP, and Java applications) using the Recorder to capture actions performed on application objects such as a text box, button, table, radio button, combo box, and list view.

Example of passing a value between bots

Learn how to pass a value from one Task Bot to another by using a dictionary variable.

Build a parent Task Bot and a child Task Bot that do the following:

- The parent bot prompts the user to enter a song title and passes it to the child bot.
- The child bot takes the input string and returns a new string to the parent bot.
- The parent bot receives the string that the child bot passes as a dictionary.

1. Build a child bot.

- a) From the Control Room interface, select **Bots > My bots**.
- b) Click **Create New > Bot**.
- c) Enter the name for the bot as `GetSongDetails`.
- d) Click **Create and Edit**.

2. Create a variable named `sMySong`.

- a) In the **Variables** panel, click the Create variable button.
- b) In **Type**, select **String** if it is not already selected.
- c) In **Name**, enter `sMySong`.
- d) Select the **Use as input** and **Use as output** check boxes.
- e) Click **Create**.

3. To build a return string, use the **String > Assign** action.

- a) From the **Actions** panel, find the **String > Assign** action, and add it to the child bot flow.
- b) In **Select the source string variable(s)/ value**, enter `I love ${sMySong} too!`.
During runtime, `${sMySong}` in the output string will be replaced with the value that the parent bot passes to the child bot.
- c) In **Select the destination string variable**, select `sMySong` to store the new string.

- d) Click **Save**.
4. Build the parent bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create New > Bot**.
 - c) Enter the name for the bot as `FavoriteSong-Parent`
 - d) Click **Create and Edit**.
5. Create a variable named `sMySong`.
6. Use the **Prompt > For value** action to capture a song title.
 - a) From the **Actions** panel, find and add the **Prompt > for value** action to the parent bot flow.
 - b) In the **Prompt window caption** field, enter `Favorite Song`.
 - c) In the **Prompt message** field, enter `Type the title of your favorite song.`
 - d) In the **Assign the value to a variable** field, enter `sMySong`.
 - e) Click **Save**.
7. Use the **Task Bot > Run** action to call the child bot:
 - a) From the **Actions** panel, find and add the **Task Bot > Run** action to the parent bot flow.
 - b) In **Task Bot to run**, select **Control Room** and then click **Choose**.
 - c) Click **Browse** and navigate to the folder that contains the child bot and select `GetSongDetails`.
 - d) In **Input values**, select **Set sMySong** and then enter `$sMySong$` in the variable field.
 - e) In **Save the outcome to a variable (option)**, select **Dictionary** and then create a variable named `dOutput`.
 - f) Click **Save**.
8. Use the **Message box** action to display the string that the child bot returns.
 - a) From the **Actions** panel, find and add the **Message box > Message box** action to the parent bot flow.
 - b) In **Enter the message box window title**, enter `Automation Anywhere Enterprise Client`.
 - c) In **Enter the message to display**, enter `$dOutput {sMySong} $`.
The name of the output variable that the child bot uses is used as the key for retrieving the value from the dictionary variable.
 - d) Click **Save**.
9. Test the bot.
 - a) Click **Run** to run the bot.
After bot is deployed, the **Favorite Song** input box opens.
 - b) In the **Favorite Song** input box, enter a song title.

- c) Click OK.
A message box should display the string that the child bot returns. If no value returns, then review the procedure to assign the incoming value to a dictionary key and a variable.

Related reference

[Dictionary package](#) on page 2406

The **Dictionary** package contains actions that enable you to do various operations on dictionary-type values.

Example of using a conditional statement

In this example, you build a bot that prints a message based on whether a cell has a value or is empty. Use the actions from the Excel basic or Excel advanced, If, and Message Box packages.

Before building this bot, save an empty Excel worksheet to the desktop.

Because this bot does not create a new Excel worksheet, you can use either the Excel basic or Excel advanced packages.

Note: All of the actions must be from the same package.

1. Open a new bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create new > Bot**.
 - c) Enter a bot name and click **Create and edit**.
2. Use the **Open** action from the Excel basic or the Excel advanced package to open the Excel sheet.
 - a) Double-click or drag the **Open** action.
 - b) Enter a session name.
 - c) Click **Browse** to provide the file path to the empty Excel worksheet on the desktop.
3. Use the **Get single cell** action to assign the value of a cell to a string variable.
 - a) Double-click or drag the **Get single cell** action from the same package that you used for the **Open** action.
 - b) Provide the session name that you used in the **Open** action.
 - c) Select the **Active cell** option.
 - d) In the **Store cell contents to** field, create the variable `Output`.
4. Use the **If** action to configure the conditional statement.
 - a) Double-click or drag the **If** action.
 - b) Select **String** from the **Condition** drop-down list.
 - c) In the **Source value** field, insert the variable `Output`.
 - d) Select **Equals to** as the **Operator**.

- e) Leave the **Target value** field empty.
5. Insert a Message box into the **If** container.
 - a) Drag the **Message box** action.
 - b) In the **Enter the message to display** field, enter `Cell is empty`.
6. Use the **Else** and **Message box** actions to configure the alternative sequence of actions.
 - a) Drag the **Else** action next to the **If** action.
 - b) Drag the **Message box** action into the **Else** container.
 - c) In the **Enter the message to display** field, enter `Cell is not empty`.
7. Click **Save**.
8. Run the bot.

As the bot runs, the message box appears with the message `Cell is empty`.
9. Enter a value into the cell located at A1 in the Excel sheet and save the sheet.
10. Run the bot.

As the bot runs, the message box appears with the message `Cell is not empty`.

Related reference

[Excel advanced package](#) on page 2479

The Excel advanced package contains actions that enable you to automate many of the repetitive tasks when working with Microsoft Excel spreadsheets.

[If package](#) on page 2619

Use the actions in the **If** package to control the sequence of execution based on one or more conditions of a task.

[Message box package](#) on page 2691

Use the **Message box** action from the **Message box** package to insert a message box that shows a message when the task runs. For example, you can insert a **Message Box** action to follow a web form so that the action displays the message: `Web Form Filled and Complete`.

Example of using Python script to join a list

Build a bot that uses a Python function to print the message `Go Be Great!`, the Automation Anywhere version of `Hello World`. In this example, the bot combines a list of string values and prints them to a message box.

To run Python script from Automation 360, you must already have the latest version of Python 3.x installed on your device.

1. Create a new bot:
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Bot**.
 - c) In the **Create Task Bot** window, enter the bot name.
 - d) Accept the default folder location: `\Bots\`

To change the default bot storage location, click **Choose** and follow the prompts.

- e) Click **Create and edit**.
2. Create a variable to hold the list values:
 - a) Click the **Create variable** icon.
 - b) Enter `lArgument` in the **Name** field.

Recommendation: Prefix the variable name with a lowercase character to indicate the variable data type.

[Variable naming](#) on page 2241

 - c) Select the **List** type and **String** subtype.
 - d) In the **Default value** field, enter the following values:
 1. **Value at 0:** Go
 2. **Value at 1:** Be
 3. **Value at 2:** Great
 4. **Value at 3:** !
 - e) Click **Create**.
3. Provide the script with a **Python Script > Open** action:
 - a) Double-click or drag the **Python Script > Open**.
 - b) Select the **Manual input** option.
 - c) Copy and paste the following text into the **Enter script here** field.

```
def data ( str ):  
    x = " ".join( str )  
    return x
```

4. Use a **Python Script > Execute function** action to tell the bot to run the script:
 - a) Double-click or drag **Python Script > Execute function**.
 - b) Enter `data` in the **Enter name of function to be executed** field.
 - c) Select the **lArgument** variable from the **Arguments to the function** drop-down list.
 - d) Create the variable `sOutput` for the **Assign the output to variable** field.
 5. Insert a **Message box** action to hold the Python function output:
 - a) Double-click or drag the **Message box > Message box** action.
 - b) In the **Enter the message to display** field, select and insert the variable `sOutput`.
 - c) Select the **Close message box after** option. Retain the default value of 5 seconds in the field.
 6. Close the script execution session with a **Python Script > Close** action:
 - a) Double-click or drag **Python Script > Close**.
-

b) Click **Save**.

7. Click the **Run** icon.

The bot generates a message box with the text Go Be Great!. After 5 seconds, the message box disappears.

To review the bot launcher logs, navigate to C:\ProgramData\AutomationAnywhere\BotRunner\Logs\\Bot_Launcher-<today's date>.log.zip. Each zipped folder contains a file with data on the code execution, which is useful for debugging.

Related reference

[Python Script package](#) on page 2789

The Python Script package contains actions that enable Python Script functions in a task.

[Message box package](#) on page 2691

Use the **Message box** action from the **Message box** package to insert a message box that shows a message when the task runs. For example, you can insert a **Message Box** action to follow a web form so that the action displays the message: Web Form Filled and Complete.

Example of using the DLL package

Build a very simple DLL that will generate a message. Create a bot to run the DLL.

This topic shows how to create a DLL package. If you do not have Microsoft Visual Studio, download the free Community version from [Microsoft Visual Studio Community IDE](#).

Create the DLL package.

- 1.** In Microsoft Visual Studio, create a new class library that will generate a file type .dll by using C#.
 - a)** Navigate to **File > New > Project**.
 - b)** Search for d11 in the **Search for templates** field.
 - c)** Select the C# library option.
 - d)** Configure your project as follows:
 - Project name: DemoDLL
 - Location: [Any]
 - Solution Name: DemoDLL
 - e)** Click **Create**.
 - f)** Copy the following code and replace the contents of class1.cs by pasting:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Threading.Tasks;

namespace DemoDLL
{
    public class CallMe
    {
        public string ImHere()
    }
}
```

```
        {  
            String Reply = "You are now inside the DemoDLL,  
ImHere function!";  
            return Reply;  
        }  
    }  
}
```

- g)** In **Solution Explorer**, right-click **Class1.cs** and rename it to "CallMe.cs".
- h)** Navigate to **File > Save All**.
- i)** Navigate to **Build > Build Solution**.
The output window confirms that the DLL package was successfully created and displays the path to your new DemoDLL.dll package in the **Output** window. Note the package location, as you will need it later to enter into the bot.

Create a bot to execute the DLL package.

- 2.** Create a bot.
 - a)** On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b)** Click **Create New > Bot**.
 - c)** Provide a name for the bot: MyDLLbot
 - d)** Enter the folder location: Bots\TaskBotExample
 - e)** Click **Create and Edit**.
- 3.** Create a variable: sReturnedString: string type.
[Create a variable](#) on page 2246
- 4.** Use a **DLL > Open** action to load your DLL package.
 - a)** From the Actions pane, double-click or drag the **DLL > Open** action.
 - b)** In the **DLL:Open, Filepath** field, select file type **Desktop file** and click **Browse** to find your DLL package. Click **Open**.
 - c)** Click **Save**.
- 5.** Use a **DLL > Run function** action to execute your DLL package.
 - a)** Double-click or drag the **DLL > Run function** action to the last line of the bot.
 - b)** Click **Get DLL Details**.
 - c)** Select **Desktop file** type and then click **Browse**. Locate your DLL package and click **Open**.
 - d)** Click **Next**.
 - e)** Expand the DemoDLL namespace and select the **CallMe** function. Select method **ImHere** and click **Apply**.
 - f)** In the **Assign the value to a variable** field, select sReturnedString.
- 6.** Use a **Message box** action to report what was returned from the DLL bot:
 - a)** Double-click or drag the **Message box** action to the last line of the bot.

- b) In the **Enter the message to display** field, type: From the DLL: "\$sReturnedString\$".
7. Click **Save**.
 8. Use the **DLL > Close** action to end the DLL session.
 - a) Double-click or drag the **DLL > Close** action to the last line of the bot.
 9. Click **Save**.
 10. Click the **List** tab to view your code in text-only mode.
Your code should look like this:

```
Start
DLL:Open "C:\myFolder\source\repos\DemoDLL\DemoDLL\bin\Debug
\DemoDLL.dll for session "Default"
DLL:Run function "ImHere" and store output in variable
  $sReturnedString$ and session "Default"
MessageBox "From the DLL: "$sReturnedString$".
DLL:Close session "Default"
End
```

11. Run your bot.
The DLL package returns a message to the bot: **From the DLL: "You are now inside the DemoDLL, ImHere function!"**.

A dynamic-link library (DLL) file contains a shared library of functions that can be used by Windows programs. The **DLL** package uses a .dll file as reference and calls functions from the bot.

Example of transferring data from CSV file to Excel worksheet

Build a bot that reads data from a CSV file and updates the data in an Excel worksheet, using actions from the CSV/TXT, Excel advanced, IF/ELSE, and Loop packages.

Before you start building the bot, create the following data sets on your desktop in the specified file formats:

Data set 1: ProductInventory.xlsx

Item number	Name	Count	Category	Unit price	Taxable
A0001	Milk	15	Grocery	3	N
A0002	Eggs	6	Grocery	4	N
A0003	Flower	3	Garden	10	Y
A0004	Table	1	Home	50	Y
A0005	Towel	4	Home	10	Y
A0006	Dog Food	16	Pet	22	N

Item number	Name	Count	Category	Unit price	Taxable
A0007	Paint	43	Home	12	Y

Data set 2: NewProductNames.csv

Item number	Name
A0005	Hand Towel
A0002	Chicken Eggs
A0003	Sunflower
A0004	Coffee Table
A0006	Dog Food - Small Dogs
A0007	Paint - Dark Blue
A0001	2% Milk

In this example, you will build a bot to update the product inventory in an Excel worksheet with new product names from a CSV file. The Excel worksheet has old product names and the CSV file has new product names. You will relate the data in the Excel worksheet and the CSV file with item number and update the Excel worksheet with the new item name corresponding to the item number. Use actions from the CSV/TXT, Excel advanced, IF/ELSE, and Loop packages

1. Create a new bot:
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Bot**.
 - c) In the **Create Task Bot** window, enter the bot name.
 - d) Accept the default folder location: \Bots\
To change the default bot storage location, click **Choose** and follow the prompts.
 - e) Click **Create and edit**.
2. Open the NewProductNames.csv file that you just created.
 - a) Double-click or drag the **CSV/TXT > Open** action.
 - b) In the **Session name** field, enter `session 1`.
 - c) Provide the file path to NewProductNames.csv.
 - d) Select the **Contains header** option.
3. Open the ProductInventory.xlsx file that you just created.
 - a) Double-click or drag the **Excel advanced > Open** action.
 - b) In the **Session name** field, enter `session 2`.
 - c) Provide the file path to ProductInventory.xlsx.
 - d) Choose to open the file in **Read-write** mode.
 - e) Select the **Contains header** option.

4. Use the **Go to cell** action to indicate the first cell in which to update the product names.
 - a) Double-click or drag the **Excel advanced > Go to cell** action.
 - b) In the **Session name** field, enter `session 2`.
 - c) Select the **Specific cell** option and enter B2.

5. Use a **Loop** action to retrieve the cell values in each row from `ProductInventory.xlsx`.
 - a) Double-click or drag the **Loop** action.
 - b) Select the **Excel Advanced > For each row in worksheet** iterator.
 - c) In the **Session name** field, enter `session 2`.
 - d) In the **Loop through** field, select **All rows**.
 - e) In the **Assign current value to this variable** field, create a `rInventory` variable.

6. Use a **Loop** action to retrieve the cell values in each row from `NewProductNames.csv`.
 - a) Drag the **Loop** action into the **For each row in worksheet Loop** container.
 - b) Select the **For each row in CSV/TXT** iterator.
 - c) In the **Session name** field, enter `session 1`.
 - d) In the **Assign current value to this variable** field, create a `rNewProduct` variable.

7. Use an **If** action to compare the item number from `ProductInventory.xlsx` to the item number from `NewProductNames.csv` to ensure they are the same before moving on to the next action.
 - a) Double-click or drag the **If** action into the **For each row in csv/txt Loop** container.
 - b) Select the **String** condition.
 - c) In the **Source value** field, input `rInventory[0]`.
 - d) Select the **Equals to (=)** operator.
 - e) In the **Target value** field, input `rNewProduct[0]`.

8. Use the **Set cell** and **Go to cell** actions to update the product name and move to the cell below.
 - a) Double-click or drag the **Excel Advanced > Set cell** action.
 - b) In the **Session name** field, enter `session 2`.
 - c) Select the **Active cell** option.
 - d) In the **Cell value** field, input `rNewProduct{Name}`
 - e) Double-click or drag the **Excel Advanced > Go to cell** action.
 - f) In the **Session name** field, enter `session 2`.
 - g) From the **Active cell** drop-down list, select **One cell below**.

9. Insert an alternative to the **If** action: if the item numbers are not the same, the bot continues to the next row in `NewProductNames.csv`.
 - a) Drag the **If > Else** action.
 - b) Drag the **Loop > Continue** action.

10. Close the files.
 - a) Double-click or drag the **Excel advanced > Close** action.
 - b) In the **Session name** field, enter `session 2`.
 - c) Select the **Save changes** option.
 - d) Double-click or drag the **CSV/TXT > Close** action.
 - e) In the **Session name** field, enter `session 1`.

11. Click **Save**.

12. Run the bot.

The bot updates the `ProductInventory.xlsx` file to look like the following table:

Data set 3: ProductInventory.xlsx

Item number	Name	Count	Category	Unit price	Taxable
A0001	2% Milk	15	Grocery	3	N
A0002	Chicken Eggs	6	Grocery	4	N
A0003	Sunflower	3	Garden	10	Y
A0004	Coffee Table	1	Home	50	Y
A0005	Hand Towel	4	Home	10	Y
A0006	Dog Food - Small Dogs	16	Pet	22	N
A0007	Paint - Dark Blue	43	Home	12	Y

[CSV/TXT package](#) on page 2362

The **CSV/TXT** package contains actions that enable you to open a CSV or text file, read data from that file, and assign the data to a Table variable. This package supports files encoded in ANSI, Unicode, UTF-8, or Windows-1251, and can process up to one million records.

[Excel advanced package](#) on page 2479

The Excel advanced package contains actions that enable you to automate many of the repetitive tasks when working with Microsoft Excel spreadsheets.

[If package](#) on page 2619

Use the actions in the **If** package to control the sequence of execution based on one or more conditions of a task.

[Loop package](#) on page 2679

Use the Loop package to run a sequence of actions repeatedly for a specific number of times or until a specific condition is met.

Run TaskBot to merge Excel sheets

Download and run sample Task Bot from the Bot Store to merge two spreadsheets.

Complete these requirements for using the example :

- Microsoft Excel must reside on the Bot Runner device
- Automation 360 Build 4088 or later
- Excel Advanced package version 2.0.0-20200422-000103 or later
- Two spreadsheets as input: Both sheets must have common data within column A, such as a product or customer number

You can manually create the spreadsheets with columns similar to the following tables 1 and 2. Sheet 1 has columns to append to sheet 2 where a common value resides in column A. The bot expects the file locations and names to be `c:\bot_test\Spreadsheet1.xlsx` and `c:\bot_test\Spreadsheet2.xlsx`.

Table 1

Item Number	Name	Count	Category	Unit Price	Taxable	Backorder	Perishable	Locale
A0001	Milk	15	Grocery	3	N	Y	Y	US
A0005	Towel	4	Home	10	Y	N	N	US
A0006	Dog Food	16	Pet	22	N	N	N	US
A0007	Paint	43	Home	12	Y	N	N	IN

Table 2

Item Number	Name	Brand	Popular	Unit Price	TTS
A0001	Milk	Wholesome Foods	Y	3	1
A0002	Eggs	Dairy Love	Y	4	1
A0003	Flower	Spring Me Up!	N	10	3
A0004	Table	Woods Are Us	N	50	10
A0005	Towel	Claire Dane	N	10	6
A0006	Dog Food	Purina	Y	22	3
A0007	Paint	Color the World	N	12	2

1. Get the [Merge Excel Sheets Example](#) bot from the Bot Store.

The bot is automatically loaded to your Automation 360 On-Premises or Cloud environment.

You will receive an email with instructions for installing the bot in Automation 360 from the Bot Store.

2. Follow the instructions carefully. If you do not have the Bot Developer role assigned, contact your administrator to add the role.
3. If your spreadsheets are not located at `c:\bot_test\Spreadsheet1.xlsx` and `c:\bot_test\Spreadsheet2.xlsx`, update lines 5 and 9 of the bot with your desktop file location.
4. Run the Task Bot.
5. Update the Task Bot with any changes that reflect your use case, and make it your own. You can also use the bot as a template for future Excel Advanced Task Bots by copying and saving it with a new name.

[Excel advanced package](#) on page 2479

The Excel advanced package contains actions that enable you to automate many of the repetitive tasks when working with Microsoft Excel spreadsheets.

Example of migrating data from Excel to a database

In this example, you build a bot to transfer values from an Excel spreadsheet to a database using actions from the Database, Excel advanced, and Loop packages.

Before you start building your bot, create the following:

- Create an Excel spreadsheet with the following values and save it (For example: Test_migration_db.xlsx)

John	Williams	jwilliams@cmail.com
Sam	Li	sam.li@xyz.org
Carl	Miller	carl@carlmillerllc.com

The screenshot shows an Excel spreadsheet with the following data:

	A	B	C	D	E	F
1	John	Williams	jwilliams@cmail.com			
2	Sam	Li	sam.li@xyz.com			
3	Carl	Miller	carl@carlmillerllc.com			

- Create an Access database table named CustomerT with the following columns: (create a database similar to the image below and save it - for example: save it as Test_Migration_db.accdb)
 - FirstName

- LastName
- Email

ID	FirstName	LastName	Email	Click to Add
(New)				

To migrate values from a spreadsheet to a table in a database, perform the following steps:

1. Create a new bot:
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Bot**.
 - c) In the **Create Task Bot** window, enter the bot name.
 - d) Accept the default folder location: \Bots\
To change the default bot storage location, click **Choose** and follow the prompts.
 - e) Click **Create and edit**.
2. Open the spreadsheet:
 - a) Double-click or drag the **Excel advanced > Open** action .
 - b) Click **Browse** to provide the file path.

Excel advanced: Open

Opens an excel spreadsheet. This action works with xlsx, xls, csv, xlsx, xlsb, xml, txt, ods, htm, htm, mhtml, mhtml, sik and pdf files.

Required bot agent version: 21.112 or above

File path
Control Room file Desktop file Variable
C:\Temp\Test_migration_db.xlsx [x] Browse...

e.g. C:\Working\Excel1.xlsx

Sheet contains a header

Specific sheet name
e.g. Sheet1 or SHEET1

Open in
 Read-only mode
 Read-write mode

- c) Select the option to open the file in **Read-write**.
3. Connect to the database:
 - a) Double-click or drag the **Database > Connect** action.
 - b) Select the **User defined** connection mode.

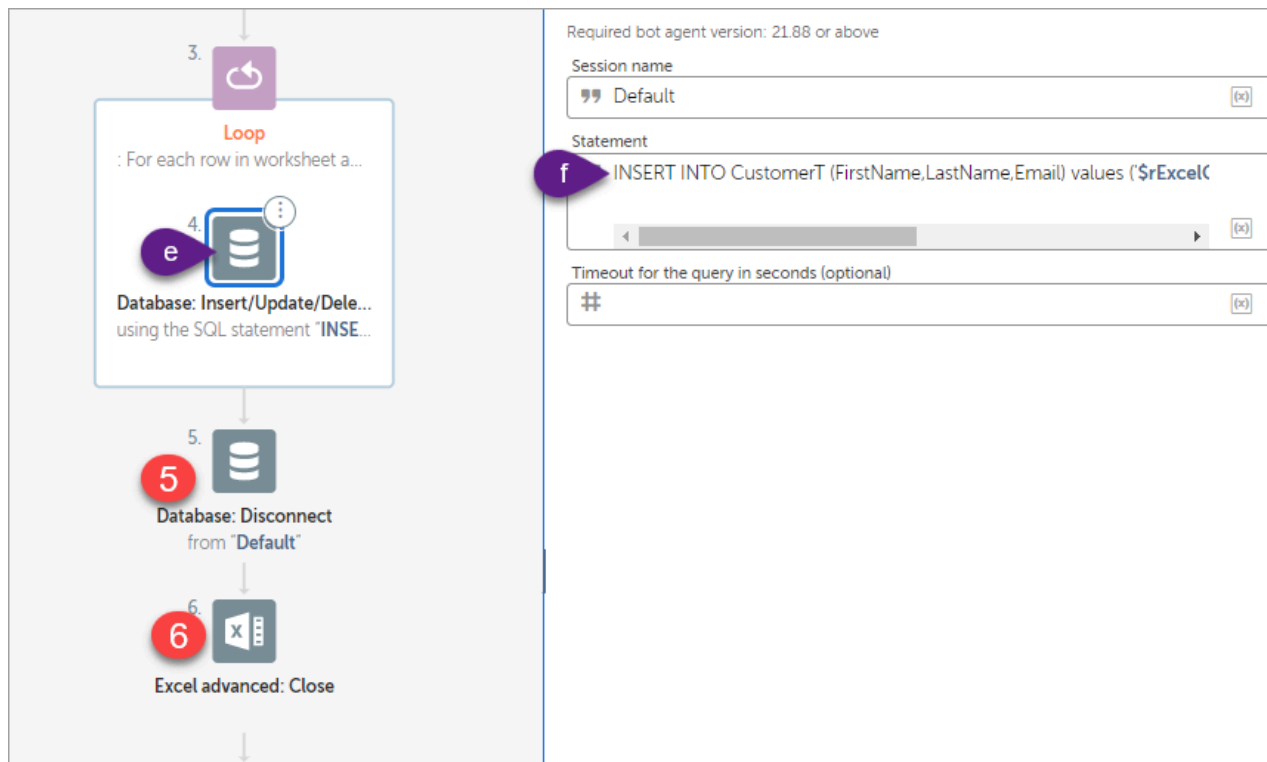

- c) Select the **Microsoft Access** database type.
 - d) Click **Browse** to provide the file path.
4. Insert the Excel values into the database, row by row:
- a) Double-click or drag the **Loop** action.
 - b) Select the **Excel advanced > For each row in worksheet** iterator.
 - c) Select **All rows** from the **Loop through** drop-down.

- d) In the Assign the current value to this variable, create the record variable `rExcelCurrentRow`.
- e) Drag the **Database > Insert/Update/Delete** action into the Loop container.

f) Enter the following SQL statement:

```
INSERT INTO customer
(
  firstname,
  lastname,
  email
)
VALUES
(
  '$rExcelCurrentRow[0]$',
  '$rExcelCurrentRow[1]$',
  '$rExcelCurrentRow[2]$$'
);
```

5. Disconnect from the database. Drag the **Database > Disconnect** action below the Loop container.
6. Close the spreadsheet. Double-click or drag **Excel advanced > Close Spreadsheet** action.
7. Click **Save**.

[Database package](#) on page 2379

Databases support internal operations of an enterprise by storing a variety of data, such as sales transactions, product catalogs, inventories, and customer profiles. Use the Database package to connect to a database, begin a transaction, and manipulate the stored data by retrieving, inserting, updating, deleting, and exporting it to a CSV file.

[Excel advanced package](#) on page 2479

The Excel advanced package contains actions that enable you to automate many of the repetitive tasks when working with Microsoft Excel spreadsheets.

[Loop package](#) on page 2679

Use the Loop package to run a sequence of actions repeatedly for a specific number of times or until a specific condition is met.

Example of reading data from a spreadsheet

Build a bot that reads data from one Excel worksheet and writes it to another worksheet.

To use the Excel advanced package, Microsoft Excel must be installed on the device where you run the sample bot.

Suppose an Order Processing team receives order data in a spreadsheet as part of the Order Fulfillment process. The team automates the process of creating a priority shipping list from the spreadsheet and sharing it with the Picking department. The sample bot in this tutorial performs the following tasks:

- Reads spreadsheet data that contains a list of orders using the Excel advanced package.
- Creates a new spreadsheet containing a list of orders that need to be shipped as a priority.

For this tutorial, you can download and use a sample Excel file from [here](#).

1. Create a new bot.
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Task Bot**.
 - c) In the **Create Task Bot** window, enter `Priority List` in **Name**.
 - d) Click **Create and edit**.
2. To read data from the spreadsheet that contains the list of orders, open the Excel sheet.
 - a) From the **Actions** panel, find and add the **Excel advanced > Open** action to the Bot editor.
 - b) Click **File** and select the sample Excel file you downloaded.
 - c) Select **Sheet contains a header**.
 - d) Select **Specific sheet name** and enter `order_list`.
 - e) In **Create Excel session**, click **Local session**, and enter `orderlist` as the session name.
3. For the list of priority orders, create a new spreadsheet.
 - a) From the **Actions** panel, find and add the **Excel advanced > Create workbook** action to the Bot editor.
 - b) In **File path**, specify a file path for the new file. For example, `C:\\bots\\priority-orders.xlsx`.
 - c) In **Sheet name**, enter `priority orders`.
 - d) In **Create Excel session**, select **Local session** and enter `prioritylist` as the session name.
 - e) Save the changes.
4. Copy the header from the source spreadsheet to the new spreadsheet.
 - a) From the **Actions** panel, find and add the **Excel advanced > Get multiple cells** action to the Bot editor.

- b) In **Select range of cells to be returned**, select **Specific rows**, and then enter 1 in both the **From row** and **to row** fields.
 - c) In **Session name**, enter `orderlist`.
 - d) To store the copied values to a variable, create and assign a variable named `HeaderData` in **Assign value to the variable**. The values are stored in a data table variable.
 - e) Save the changes.
5. Write the copied header to the new sheet.
 - a) Find and add the **Excel advanced > Write from data table** action to the Bot editor.
 - b) In **Enter data table variable**, select **HeaderData**.
 - c) Click **Specific worksheet** and enter `priority orders`.
 - d) In **Specify the first cell**, enter `A1`.
 - e) In **Session name**, enter `prioritylist`.
 - f) Save the changes.
6. Before you write the data to the new spreadsheet, make sure that the A2 cell is selected on the new worksheet. To do so:
 - a) From the **Actions** panel, find and add the **Excel advanced > Go to cell** action to the Bot editor.
 - b) In **Specific cell**, enter `A2`.
 - c) In **Session name**, enter `prioritylist`.
 - d) Save the changes.
7. Loop through the list of orders in the source spreadsheet.
 - a) From the **Actions** panel, find and add the **Loop** action to the Bot editor.
 - b) From **Iterator**, select **For each row in worksheet** for Excel advanced.
 - c) In **Loop through**, select **All rows**.
 - d) In **Session name**, enter `orderlist`.
 - e) In **Assign the current value to this variable**, select **Record**, and then create a variable named `order-record`.
 - f) Save changes.
8. Select the records where ShippingType equals Priority.
 - a) a. From the **Actions** panel, find and add the **If** action within the **Loop** action.
 - b) In **Condition**, select **String** condition.
 - c) In **Source value**, enter `$order_record[4]$` to select the fifth column in the current record.
 - d) In **Operator**, select **Equal to(=)**.
 - e) In **Target value**, enter `Priority`.
 - f) Save the changes.

9. If a matching record is found, write the record to the new spreadsheet. You can achieve this by using the Set cell action as many times as the number of columns in the source data. However, this example uses the Loop action to achieve the same result.
 - a) From the **Actions** panel, find and add the **Loop** action within the **If** action.
 - b) From **Iterator**, select **For each value in record**.
 - c) In **Record variable**, select **order-record**.
 - d) In **Assign the current value to this variable**, select create a variable named **RecordValue**.
 - e) Save changes.
 - f) On the **Variables** panel, create a variable with the following details:
 - In **Name**, enter RecordValueCounter
 - In **Type**, select **Number**.
 - In **Default value**, enter 0.
 - g) From the **Actions** panel, find and add the **Excel advanced > Set cell** action.
 - h) Make sure **Active cell** is selected.
 - i) In **Cell value**, enter `$order-record[$recordValueCounter$]$`.
 - j) In **Session name**, enter `prioritylist`.
 - k) To move the cursor to the next cell in the row, find and add the **Excel advanced > Go to cell** action, and then select **One cell to the right** in **Active cell**.
 - l) In **Session name**, enter `prioritylist`.
 - m) To increment the recordValueCounter variable, find and add the **Number > Increment** action. Select **recordValueCounter** in both **Enter number** and **Assign the output value to a variable** fields. In **Enter increment** value, enter 1.
 - n) Save the changes.
10. Reset the recordValueCounter variable to zero.
 - a) Find and add the **Number > Decrement** action after the inner loop but within the **If** action.
 - b) Select **recordValueCounter** in both **Enter number** and **Assign the output value to a variable** fields.
 - c) In **Enter increment value**, enter 7.
 - d) Save the changes.
11. Move the cursor to the next row before the next iteration.
 - a) Find and add the **Excel advanced > Go to cell** action within the first **Loop** action (after the **Decrement** action).
 - b) Click **Active cell** and select **Beginning of the row**.
 - c) In **Session name**, enter `prioritylist`.
 - d) Find and add the **Excel advanced > Go to cell** action.
 - e) Click **Active cell** and select **One cell below**.
 - f) In **Session name**, enter `prioritylist`.

g) Save the changes.

12. Run the bot.

Example of using the Run action

The **Run** action from the Task Bot package enables you to run and pass values to one or more child bots. In this example, you use the **Run** action to pass two values from a parent bot to the child bot; the child bot adds the values and passes the sum back to the parent bot.

This example demonstrates the following:

Modularization

Modularization separates a Task Bot into several bots, where each bot is built with all the actions necessary to perform one specific function of the greater task.

In this example, you build a single child bot to add the values. You can build several child bots, with each performing a different mathematical operation, and edit the parent bot to call whichever one you want to use.

Reusability

Reusability enables the user to build a bot once, and then use that bot to automate many processes.

The child bot contains only the actions necessary to add the values and print them to a Message Box. Also, the bot adds two variables instead of hard-coded values. As a result, this bot can be reused for any task that involves an addition operation.

Data control

Because the child bot accepts and returns values only through the use of variables, it does not hold data. This minimizes the chance of data leakage.

To run a Task Bot from the current task, perform these steps:

Build the child bot.

- 1.** Open a new bot.
 - a)** On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b)** Click **Create a bot**.
 - c)** Enter the bot name `AddChildBot`.
 - d)** Enter the folder location `Bots\TaskBotExample`.
To change where your bot is stored, click **Choose** and follow the prompts.
 - e)** Click **Create and Edit**.
- 2.** Create the following variables:

- v1: number type; use as input
- v2: number type; use as input
- nSum: number type
- sSum: string type; use as output

[Create a variable](#) on page 2246

3. Use a **Number > Assign** action to perform the mathematical operation.
 - a) Double-click or drag the **Number > Assign** action.
 - b) In the **Select the source string variable/ value** field, enter the following expression: $\$v1\$ + \$v2\$$
 - c) Select nSum from the **Select destination number variable** list.
4. Use the **Number > To string** action to convert the value so it can be printed to a Message Box.
 - a) Double-click or drag the **Number > To string** action.
 - b) In the **Enter a number** field, enter the following expression: $\$nSum\$$
 - c) Select sSum from the **Assign output to variable** list.
5. Click **Save**.
6. Click **Close**.

Build the parent bot.

7. Open a new bot.
 - a) On the left panel, click **Automation**
A list of available bots and forms is displayed.
 - b) Click **Create a bot**.
 - c) Enter the bot name MathBot.
 - d) Enter the folder location `\Bots\TaskBotExample`.
To change where your bot is stored, click **Choose** and follow the prompts.
 - e) Click **Create and Edit**.
8. Create a Dictionary variable of Any subtype named dSums to accept the values passed from the child bot.
Use the Any subtype to enable the parent bot to accept String, Number, or Boolean type values.
9. Insert a **Task Bot > Run** action to specify the values for the mathematical operation and the output variable to hold the sum.
 - a) Double-click or drag the **Task Bot > Run** action.
 - b) Click **Browse** to navigate to `Bots\TaskBotExample\AddChildBot`.
 - c) Enter the following values in the **Input values** fields:
 - v1: 12
 - v2: 54
 - d) Select dSums from the **Assign output to variable** list.

Note: Use a Dictionary variable to hold the output of the **Run** action in order to make the parent bot more versatile. This way a parent bot can handle different child bots regardless of whether they return a single value or several values.

10. Use a Message Box to retrieve and print the sum.

The variable `sSum` retrieved from the child bot is a key in the Dictionary variable `dSums`.

Note: You must know the variable names from the child bot to extract them from the parent bot. The interface does not automatically import the variable names to the parent bot.

- a) Double-click or drag the **Message box** action.
- b) Enter `$dSums { sSum } $` in the **Message to display** field.

11. Click **Save**.

12. Click **Run**.

The bot runs and the Message Box appears containing the sum 66.

Related reference

[Task Bot package](#) on page 2980

Use the **Run**, **Pause**, and **Stop** actions in the Task Bot package to manage running one or more child bots from a parent bot or with a third-party software using an API.

[Message box package](#) on page 2691

Use the **Message box** action from the **Message box** package to insert a message box that shows a message when the task runs. For example, you can insert a **Message Box** action to follow a web form so that the action displays the message: `Web Form Filled and Complete`.

Example of using the SOAP web service action

Use the **SOAP web service** action to pass two numeric values and return the sum from an online calculator application.

To make a SOAP web services call, perform the following steps:

1. Double-click or drag the **SOAP web services** action.
2. Select a connection method:
 - To connect using a URI, enter the URI, for example, `http://www.dneonline.com/calculator.asmx?WSDL`.
 - To connect using a file, select a file from the Control Room or the Desktop, or insert a variable.
3. Optional: Enter the SOAP endpoint in the **Address location** field.

If you specify the address location, the bot uses it during execution; otherwise, the bot uses the address location from the WSDL file.

Note: If you are creating the SOAP URI manually and not using the **Build SOAP request** option, go to step 6 on page 3098.

4. Click **Build SOAP request**.

The **SOAP request** window appears, displaying the services and ports, with details about their operations and parameter.

5. In the **SOAP request** window, expand the service for which you want to view the list of ports. Click the required port to display the list of available operations. Select the required operation and click **Apply** to retrieve the operation details from the SOAP request.

If you use the **Build SOAP request** option, **Services, Port, Operation, and Operation parameters** fields are automatically populated with details based on the operation you selected. Go to step 10 on page 3098.

6. In the **Service** field, enter the service name.

This field identifies the collection of ports supported by the web service. It holds the @service name value for a SOAP web service call, for example, Calculator.

7. Optional: In the **Port** field, enter the endpoint to connect with.

If you do not specify a port, the bot will use the first port mentioned in the WSDL file based on the service selected. However, if that port is not supported by the SOAP web service, bot execution will fail.

This field holds the @binding name value for a SOAP web service call, for example, CalculatorSoap.

8. Select the **SOAP version** of the endpoint that you specified in the **Port** field.

Choose either **1.1** or **1.2**.

9. In the **Operation** field, enter the name of the service function for the endpoint that you specified in the **Port** field.

The bot execution fails if either of the following is true:

- The port mentioned in the port field does not have any operations.
- The operation mentioned in the SOAP request for the port is unavailable.

This field holds the @operation name value for a SOAP web service call, for example, Add.

10. Select **Operation parameters** or **Raw data parameters** to provide the parameter details.

Note: If you have selected **Build SOAP request**, the parameter details table in the **Operation** tab is automatically populated with the parameters of the selected operation. Provide values for these parameters. You can also add, edit, or delete the parameters for a particular operation.

- If you select **Operation parameters**, enter the name and value of each parameter. For example, enter the following values:

- a) intA in the first **Name** field
- b) 10 in the first **Value** field
- c) intB in the second **Name** field
- d) 20 in the second **Value** field

- If you choose **Raw data parameters**, select **Parameters** or **Credential parameters**.

11. **Parameters:** You can use the credential values from the credential locker without exposing the credentials (username or password) in plain text in the raw data. To do so, you must first map the credential in the credential mapper and use the reference name in the raw data within curly braces.

For example, in the raw data, you provided the password in plain text to authenticate to the server.

```
<aut:AuthHeader>
<aut>Password> abc@123</aut>Password>
</aut:AuthHeader>
```

To use the password from the credential locker, perform the following steps:

a) Click Add substitution.

Enter the reference name, for example, `pwd`, in the **Name in XML** field. Select **Credential** to use a value available in the credential vault, **Variable** to use a credential variable, or **Insecure string** to manually specify the value you want to use.

For more information about credential vaults and how to use them, see [Credentials and lockers in the Credential Vault](#) on page 1796.

b) Click Add

c) Specify the reference in the raw data within curly braces, as follows:

```
<aut:AuthHeader>
<aut>Password>{{pwd}}</aut>Password>
</aut:AuthHeader>
```

The reference name `pwd` specified in raw data will substitute the corresponding value stored in the credential vault.

Ensure that you enter the reference name in the same format as specified in **Add substitution**. For example, if you have entered `password` as reference name in the raw data, when you run the bot, the bot will encounter an error.

- 12. Credential parameters:** If you want to enter raw data parameters as credential. You can choose **Credential** to use a value available in the Credential Vault or select **Variable** to use a credential variable or **Insecure string** to manually specify the value you want to use.
- 13. Select No Authentication or Basic** from the **Authentication Mode** list.
 - If you select **No Authentication**, proceed to the next step.
 - If you select **Basic**, enter your credentials.
- 14. Optional:** Provide a Client certificate by selecting a file from the Control Room or your desktop, or insert a variable.
- 15. Optional:** Provide custom headers.
- 16. Optional:** Provide a file to save the XML output.
- 17. Select Complete response or Selected response** to narrow the scope of the response.
 - If you select **Complete response**, proceed to the next step.
 - If you select **Selected response**, perform the following steps if you are creating the Xpath expression manually and not using the **Build Xpath** option.
 - a) Provide the XPath expression.** For example:

```
/*[local-name()='Envelope' and namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/']/*[local-name()='Body' and namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/']/*[local-name()='AddResponse' and namespace-uri()='http://
```

```
tempuri.org/']/*[local-name()='AddResult' and namespace-uri()='http://tempuri.org/']
```

- b) Select a section of the XML output: **Values**, **Inner XML**, or **Outer XML**.
- c) If you select the option **Values**, choose return content as: **String delimited by** or **List of strings**.

- If you select **String delimited by**, choose a delimiter option: **Pipe**, **Semicolon**, or **Custom**.

If you select **Custom**, enter variables or characters in the **Custom Delimiter** (optional) field.

Note: The special character dollar sign (\$) as delimiter is not supported.

- Select **List of strings** to return the output of the soap response as list of strings.

Note: You can only specify a list type of variable with data type as strings.

18. Click **Build Xpath**.

The Output preview window appears.

19. Select the appropriate node from the response body. The XML path is automatically created. Click **Apply**.

If you use the **Build Xpath** option, **XPath expression** and **Value** fields are automatically populated with details based on the operation you selected.

20. Optional: To set a time-out value when you send a SOAP request and receive a response, in the **Wait for action to complete** field, specify the wait time (in milliseconds).

By default, the wait time is 60000 milliseconds.

21. Configure the P12 certificate:

- To get the SSL certification file, select one of the following options: **Control Room file**, **Desktop file**, or **Variable**
- Configure the Keystore properties:
 - **Keystore file (Optional):** To provide the keystore file in .p12 format, select one of the following options: **Control Room file**, **Desktop file**, or **Variable**. The keystore file includes the client's private key and certificate.
 - **Keystore password (Optional):** To provide the password for the keystore file, select one of the following options: **Credential**, **Variable**, or **Insecure string**. The password is used to access the keystore file.

22. Select a variable to store the XML output.

For example, prompt-assignment

23. Verify the output of the **SOAP web service** action by inserting a **Message box** action with the variable prompt-assignment in the body message.

When you run the bot, the message box should show 30.

[SOAP Web Service package](#) on page 2955

Use the **SOAP web service** action from the SOAP Web Service package to access and exchange information between two systems in XML format.

Example of using Get structure command from SAP BAPI package

Using the SAP BAPI package, build a bot that inputs a structure to get data.

Download the SAP Java connector and DLL from the SAP website.

In this tutorial, you will build a bot that invokes BAPI_FLIGHT_GETLIST from the SAP demo Flight Data application. When executed, the bot calls the BAPI function by inputting an airline ID and destination details, gets a list of flights, and writes the response data to a CSV file.

You will use the following import parameters to limit your search:

- AIRLINE: Use the parameter to pass the airline ID.
- DESTINATION_FROM: Use the parameter to get the structure and pass the city name and airport ID.

The tutorial is intended to demonstrate how to perform the following actions:

- Get the structure of an import parameter.
 - Set the values for the fields in the retrieved structure.
 - Get response data in a table based on the input data.
1. Create a Task Bot named `SAP-BAPI-FlightListReport`.
 - a) Log in to Control Room.
 - b) On the left pane, click **Automation**.
 - c) Click the **Create a bot** icon.
 - d) In the **Name** field, enter `SAP-BAPI-FlightListReport`, and click **Create & Edit**.
 2. To connect the bot to your SAP system, from the **Actions** panel, find **SAP BAPI > Connect** action and add it to the bot.
 - a) In **JCo: SAP Java Connector package**, specify the path to the Java connector `.jar` file.
 - b) In **JCo DLL dependency**, specify the path to the DLL file.
 - c) Choose **Custom Application Server** as **Connection Type**.
 - d) In **Application server host name**, specify the host name of the SAP application server.

Note: As a best practice, use the `<code>` to specify sensitive information such as host name, user name, and password.

 - e) In **System number**, enter the instance number.
 - f) In **SAP instance system ID**, enter the system ID.
 - g) In **Client number**, enter the client number.
 - h) In **Logon language code**, enter **EN** or the language specific to your system.
 - i) In **Router string**, enter the SAP router string.
 - j) In **Username**, enter your SAP user name.

- k) In **Password**, enter your password.
 - l) Run the to test the connection.
If the specified connection properties are correct, the bot is executed successfully.
- 3. To create a function, add the **SAP BAPI > Create function** action.
 - a) In **Function alias name**, enter `getFlightListByAirline`.
 - b) In **BAPI name**, enter `BAPI_FLIGHT_GETLIST`.
- 4. To filter the data by an airline name, add the **SAP BAPI > Set field value** action.
 - a) In **Function alias name**, enter `getFlightListByAirline`.
 - b) Click the **Function** tab.
 - c) In **Field name**, enter `AIRLINE` as the input parameter name.
 - d) In **Field value**, enter `AZ`.
- 5. To limit the selection by the airport and the destination city, get the structure of the `DESTINATION_FROM` import parameter first, and then set values for the fields in the retrieved structure. To do this, add the **SAP BAPI > Get structure** action.
 - a) In **Function alias name**, enter `getFlightListByAirline`.
 - b) In **Structure name**, enter `DESTINATION_FROM`.
 - c) To assign the retrieved structure to an alias, click the **Alias** tab in **Destination**, and enter `destinationFrom` in **Create structure alias**.
You can now use the alias to set values for the fields in the retrieved structure.
- 6. To set a value for the `AIRPORT ID` field in the `DESTINATION_FROM` parameter, add the **SAP BAPI > Set field value** action.
 - a) In **Function alias name**, enter `getFlightListByAirline`.
 - b) In **Source**, click the **Structure** tab.
 - c) In **Structure alias**, enter `destinationFrom`.
 - d) In **Field name**, enter `AIRPORTID`.
 - e) In **Field value**, enter `FCO`.
- 7. To set a value for the `CITY` field in the `DESTINATION_FROM` parameter, add the **SAP BAPI > Set field value** action.
 - a) In **Function alias name**, enter `getFlightListByAirline`.
 - b) In **Source**, click the **Structure** tab.
 - c) In **Structure alias**, enter `destinationFrom`.
 - d) In **Field name**, enter `CITY`.
 - e) In **Field value**, enter `ROME`.
- 8. To execute `BAPI_FLIGHT_GETLIST`, add the **SAP BAPI > Run function** action.
 - a) In **Function alias name**, enter `getFlightListByAirline`.
- 9. To get the filtered data from the `FLIGHT_LIST` table, add the **SAP BAPI > Get table** action.

- a) In **Function alias name**, enter `getFlightListByAirline`.
 - b) In **Table name**, click the `FLIGHT_LIST` tab.
 - c) In **Destination**, click **Variable** to store the retrieved table data in memory.
 - d) In **Save the outcome to a variable**, create a variable named `tblFlightList` by clicking **(x)**.
10. To write the data from the retrieved table to a CSV file, add the **Data Table > Write to file** action.
- a) In **Data table**, select `tblFlightList`.
 - b) In **Enter file name**, specify the path to the CSV file to which you want to write the data.
 - c) Select **Create folders/files if it doesn't exist**.
 - d) Click **Overwrite existing file**.
11. Save and then run the bot.

Example of writing data to SAP using SAP BAPI package

Using the SAP BAPI package, build a bot that writes data to the SAP database.

Download the SAP Java connector and DLL from the SAP website.

In this tutorial, you will build a bot that invokes `BAPI_FLFCUST_CREATEFROMDATA` from the SAP demo Flight Data application. You will use the `CUSTOMER_DATA` import parameter to pass the customer data to the BAPI. When executed, the bot creates a new customer record in SAP database and displays the customer number returned by the BAPI.

The tutorial demonstrates how to perform the following actions:

- Use the Get structure command to set values for the import parameters.
 - Create a new record in an SAP table.
 - Receive a response from a BAPI.
1. Create a bot named `SAP-BAPI-CreateNewFlightCustomer`.
 - a) Log in to the Control Room.
 - b) On the left pane, click **Automation**.
 - c) Click the **Create a bot** icon.
 - d) In the **Name** field, enter `SAP-BAPI-CreateNewFlightCustomer`, and click **Create & Edit**.
 2. To connect the bot to your SAP system, from the **Actions** panel, find **SAP BAPI > Connect** action and add it to the bot.
 - a) In **JCo: SAP Java Connector package**, specify the path to the Java connector `.jar` file.
 - b) In **JCo DLL dependency**, specify the path to the DLL file.
 - c) Choose **Custom Application Server** as **Connection Type**.
 - d) In **Application server host name**, specify the host name of the SAP application server.

Note: As a best practice, use the `*****` to specify sensitive information such as host name, user name, and password.

- e) In **System number**, enter the instance number.
 - f) In **SAP instance system ID**, enter the system ID.
 - g) In **Client number**, enter the client number.
 - h) In **Logon language code**, enter **EN** or the language specific to your system.
 - i) In **Router string**, enter the SAP router string.
 - j) In **Username**, enter your SAP user name.
 - k) In **Password**, enter your password.
 - l) Run the `testConnection` to test the connection.
If the specified connection properties are correct, the bot is executed successfully.
3. To create a function, add the **SAP BAPI > Create function** action.
- a) In **Function alias name**, enter `createNewFlightCustomer`.
 - b) In **BAPI name**, enter `BAPI_FLCUST_CREATEFROMDATA`.
4. Because the `CUSTOMER_DATA` parameter is of the type structure, get the structure of the import parameter and assign it to an alias. To do this, add the **SAP BAPI > Get structure** action.
- a) In **Function alias name**, enter `createNewFlightCustomer`.
 - b) In **Structure name**, enter `CUSTOMER_DATA`.
 - c) To store the retrieved structure as an alias, click the **Alias** tab in **Destination**.
 - d) In **Create structure alias**, enter `CustomerData`.
You will use the alias to set values for the import field within the retrieved structure.
5. To set the value for the `CUSTNAME` field, add the **SAP BAPI > Set field value** action.
- a) In **Function alias name**, enter `createNewFlightCustomer`.
 - b) In **Source**, click the **Structure** tab.
 - c) In **Structure alias**, enter `CustomerData`.
 - d) In **Field name**, enter `CUSTNAME`.
 - e) In **Field value**, enter `John Doe`.
6. Repeat Step 5 to add and configure the **Set field value** action for each of the following fields:

Field name	Field value
STREET	testStreet
POSTCODE	101001
CITY	testCity
COUNTR	US
COUNTR	00000000

Field name	Field value
EMAIL	test@example.com
CUSTTYPE	P

7. To execute BAPI_FLICUST_CREATEFROMDATA, add the **SAP BAPI > Run function** action.
 - a) In **Function alias name**, enter createNewFlightCustomer.

Note: If you want BAPI_FLICUST_CREATEFROMDATA to write the data to SAP database, you must select the **End sequence** and the **Commit transaction** options. If you select the **End sequence** option, ensure that you select the **Begin sequence** option in the **Create function** action.

The sample bot created with the help of this tutorial is intended to demonstrate how the Create() BAPIs work when the SAP BAPI package is used. It is not intended to modify the database.

-
- The BAPI assigns and returns a customer number after a new customer record is created.
8. To get the number into a variable, add the **SAP BAPI > Get field value** action.
 - a) In **Function alias name**, enter createNewFlightCustomer.
 - b) In **Source**, click the **Function** tab.
 - c) In **Field name**, enter CUSTOMERNUMBER
 - d) In **Save the outcome to a variable**, create a variable named strCustomerNumber by clicking **(x)** and select the variable.
 9. To display the customer number, add the **Message Box** action.
 - a) In **Enter the message to display**, select the strCustomerNumber variable.
 10. Save and run the bot.

Example of using Run standard workflow from SAP BAPI package

Using the Run standard workflow action from the SAP BAPI package, build a bot that retrieves data from SAP systems.

Download the SAP Java connector and DLL from the SAP website.

In this tutorial, you will build a bot that uses the Run standard workflow action. The Run standard workflow action provides a user interface that enables you to select BAPIs and configure the parameters for the selected BAPI.

By using this single SAP BAPI package action, you will perform the following actions:

- Select a BAPI (BAPI_FLIGHT_CHECKAVAILABILITY) from a list of function modules available in the connected SAP system.
- Set values for the import and export parameters of the selected BAPI.
- Assign retrieved structure or tables to dictionary or table variables.

When executed, the bot gets flight availability data based on the input data, and writes it to a CSV file.

1. Create a bot named `SAP-BAPI-CheckFlightAvailability`.
 - a) Log in to the Control Room.
 - b) On the left pane, click **Automation**.
 - c) Click the **Create a bot** icon.
 - d) In the **Name** field, enter `SAP-BAPI-CheckFlightAvailability`, and click **Create & Edit**.

2. To connect the bot to your SAP system, from the **Actions** panel, find **SAP BAPI > Connect** action and add it to the bot.
 - a) In **JCo: SAP Java Connector package**, specify the path to the Java connector `.jar` file.
 - b) In **JCo DLL dependency**, specify the path to the DLL file.
 - c) Choose **Custom Application Server** as **Connection Type**.
 - d) In **Application server host name**, specify the host name of the SAP application server.

Note: As a best practice, use the `*****` to specify sensitive information such as host name, user name, and password.

- e) In **System number**, enter the instance number.
 - f) In **SAP instance system ID**, enter the system ID.
 - g) In **Client number**, enter the client number.
 - h) In **Logon language code**, enter **EN** or the language specific to your system.
 - i) In **Router string**, enter the SAP router string.
 - j) In **Username**, enter your SAP user name.
 - k) In **Password**, enter your password.
 - l) Run the bot to test the connection.
If the specified connection properties are correct, the bot is executed successfully.
3. From the **Actions** panel, find **SAP BAPI > Run standard workflow** action after the **Connect** action.
 4. Select a BAPI.
 - a) Click the **Select workflow** option.
 - b) In the **Standard BAPI Selector** window, from **Select Standard BAPI**, expand **SAP Modules**.
 - c) Find and expand **Flight with connection data (SAP training)**.
 - d) In **Flight with connection data (SAP training)**, expand **General > Create**, select **BAPI_FLIGHT_CHECKAVAILABILITY**, and then click **Select**.

 5. Specify values for the fields in the import parameter. Do the following in **Import to BAPI**:
 - a) Click the vertical ellipsis option for the **AIRLINEID** field, and select **Edit**.
 - b) In **Value**, enter `DL` and click **Apply**.
 - c) Click the vertical ellipsis option for the **CONNECTIONID** field, and select **Edit**.

- d) In **Value**, enter 1699 and click **Apply**.
- e) Click the vertical ellipsis option for the **FLIGHTDATE** field, and select **Edit**.
- f) In **Value**, enter 20170418 and click **Apply**.
The Java connector for SAP systems takes the date values in the yyyyymmdd format.

BAPI_FLIGHT_CHECKAVAILABILITY returns data in the AVAILABILITY export parameter, which is of the type structure.

6. In **Export to BAPI**, perform the following steps:
 - a) Click the ellipsis option for the **AVAILABILITY** field.
 - b) On the **Availability** window, select the **Field name** check box to select all fields within the structure, and then click **Apply**.
7. Store the data that the BAPI exports to a variable.
 - a) In **Save exported structures and scalars**, create a variable by clicking **(x)** and name it ReturnStructure.
8. In **Save exported structures and scalars**, create a variable by clicking **(x)** and name it ReturnStructure.
9. Save the **Run standard workflow** action.
10. Convert the exported data to a table.
 - a) From the **Actions** panel, find **Dictionary > Get** action, and add it after the **Run standard workflow** action.
 - b) Click inside **Dictionary variable** and select ReturnStructure.
 - c) In **Key**, enter AVAILABILITY.
 - d) In **Assign the output to variable**, create a variable by clicking **(x)** and name it Availability.
11. To write the data from the retrieved table to a CSV file, add the **Data Table > Write to file** action.
 - a) In **Data table**, select Availability.
 - b) In **Enter file name**, specify the path to the CSV file, to which you want to write the data.
 - c) Select **Create folders/files if it doesn't exist**.
 - d) Click **Overwrite existing file**.
12. Save and run the bot.

Example of using the VBScript package in a resilient bot

Build a bot that executes a Microsoft Visual Basic script. Use the Try/Catch package to gracefully end the bot if it fails, making it resilient to crashes. A resilient bot allows scheduled and queued bots to continue even if the current bot encounters an error.

In this bot, you ask the user to provide a number. The bot passes the number to a Microsoft Visual Basic script to multiply by pi and return the value. The bot then reports the result to the user. You can use the **VBScript** action to either import an external script or type it directly into your bot.

In this example, you manually type the script. You also add resiliency to the bot by adding error handling.

1. Create a bot:
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create New > Bot**.
 - c) Provide a name for the bot: `MultiplyPi`
 - d) Enter the folder location: `Bots\TaskBotExample`
 - e) Click **Create and Edit**.

2. Create a variable: `nPromptAnswer`:
 - Type: **Number**
 - Name: `nPromptAnswer`

[Create a variable](#) on page 2246

3. Create a variable: `lNumbersForPi`:
 - Type: **List**
 - Subtype: **Number**
 - Name: `lNumbersForPi`

4. Click **Save**.

5. Use the **Prompt > For value** action to ask the user for a number.
 - a) Click the **Show** link on the Actions pane.
 - b) Double-click or drag the **Prompt For value** action to add it to the bot.
 - c) In the **Prompt window caption** field, type: `Any Number`
 - d) In the **Prompt message** field, type: `Enter any number to multiply by pi.`
 - e) In the **Assign the value to a variable** field, select **prompt-assignment**.

6. Click **Save**.

7. Use the **Error handler > Try** action to gracefully end the bot if there was an error, such as the user not entering a number.
 - a) Double-click or drag the **Error handler > Try** action.
 - b) Drag the **Prompt > For value** action under the **Error handler > Try** action.

8. Click **Save**.

9. Convert the **prompt-assignment** (string) to a number value.
 - a) Double-click or drag the **String > To number** action, adding it as the last line before the **Error handler: Catch** action.
 - b) In the **Enter the string** field, press F2 to open the list of your variables, and select **prompt-assignment**.
 - c) Click **Yes, insert**.
 - d) In the **Assign the output to variable** field, select `nPromptAnswer`.

10. Click **Save**.
11. Copy the number value to the first item in the list of numbers to pass to VBScript.
 - a) Double-click or drag the **List > Add item** action, adding it as the last line before the **Error handler: Catch** action.
 - b) In the **List variable** field, select **INumbersForPi**.
 - c) In the **Item to be added** field, select **nPromptAnswer**.

12. Click **Save**.

13. Use the **VBScript > Open** action to provide your Visual Basic source code.
 - a) Double-click or drag the **VBScript Open** action, adding it as the last line before the **Error handler: Catch** action.
 - b) In the **VBScript** options, select **Manual Input**.
 - c) Copy the following code and paste it into the **Enter script here** field:

```
Dim Arg, var1, var2
Set Arg = WScript.Arguments
Function MultiplyPi (Arg)
    var1 = Arg(0)
    var2 = 3.14159
    MultiplyPi = cdbl(var1)*var2
End Function
```

14. Click **Save**.
15. Use the **VBScript > Run function** action to execute the script.
 - a) Double-click or drag the **VBScript Run function** action, adding it as the last line before the **Error handler: Catch** action.
 - b) In the **Enter the name of the function to be executed (optional)** type `MultiplyPi`.
 - c) In the **Parameters (optional)** field, select **INumbersForPi** variable.
 - d) In the **Assign the output to variable (optional)** field, select **prompt-assignment**.

16. Click **Save**.

17. Use the **VBScript > Close** action to end the session.
 - a) Double-click or drag the **VBScript Close** action, adding it as the last line before the **Error handler: Catch** action.

18. Click **Save**.

19. Print the answer generated in the VBScript on the screen.
 - a) Double-click or drag the **Message box** action, adding it as the last line before the **Error handler: Catch** action.
 - b) In the **Enter the message to display** field, type `Pi times your number is:` , then press F2 to open the list of your variables. Select **prompt-assignment**.
 - c) Click **Yes, insert**.

20. Click **Save**.

21. Notify the user if an error occurred and end the bot gracefully.
 - a) Click the **Error handler: Catch AllErrors** action once so that it is highlighted in your bot.

- b) Double-click or drag the **Message box** action to insert it as the last bot action.
- c) In the **Enter the message to display** field, type Bot failed. Please be sure to enter only numbers..

22. Click **Save**.
23. Click the **List** tab to view your code as text only.

Your code should look like this:

```
Start
Error handler: Try
  Prompt: For value during bot execution and assign the value
  $prompt-assignment$
  String: To number Convert string $prompt-assignment$ to a number
  and assign it to number variable $nPromptAnswer$
  List: Add item $nPromptAnswer$ to $lNumbersForPi$
  VBScript: Open VBScript manual script of 7 lines
  VBScript: Run function "MultiplyPi"
  VBScript: Close VBScript "Default"
  Message box "Pi times your number is: $prompt-assignment$"
Error handler: Catch AllErrors
  Message box "Bot failed. Please be sure to enter only numbers."
End
```

24. Run your bot.
25. When the bot runs successfully, a message box displays the calculated number. View the message and click **Close**. You can test the resiliency of your bot by running the bot again and entering a letter instead of a number.

[VBScript package](#) on page 3023

The VBScript package contains actions that enable VBScript functions in a task.

Build a Bot Insight dashboard bot

In this example, you build a bot that retrieves data from a website to create visualizations in Bot Insight.

Configure an empty string variable named sNu11.

[Create a variable](#) on page 2246

1. Create a new bot:
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Bot**.
 - c) In the **Create Task Bot** window, enter the bot name.
 - d) Accept the default folder location: \Bots\
To change the default bot storage location, click **Choose** and follow the prompts.
 - e) Click **Create and edit**.
2. Open a browser window to the web page from which you want to extract the table.
 - a) Double-click or drag the **Browser > Launch website** action.

- b) In the URL field, enter `https://www.statista.com/statistics/183483/ranking-of-languages-spoken-at-home-in-the-us-in-2008/`.
- c) Select the Internet Explorer browser.

Note: Use Microsoft Internet Explorer because it reliably launches the website in a new window, even if another window is already open. Other browsers might launch the website in a new tab if there is an open window.

- d) Click **Save**.
 - e) Click **Run**.
The bot opens the window.
3. Select the table for extraction.
- a) Double-click or drag the **Recorder > Capture** action.
 - b) Click the **Window** tab and select the **Languages spoken in the United States 2018 | Statista** window from the drop-down list.
If the window title does not appear in the list, click **Refresh**.
 - c) Click **Capture object**.
The **Languages spoken in the United States 2018 | Statista** window is activated.
 - d) Hover over the table until an orange box that surrounds the entire table appears.
 - e) Click the table.
 - f) Return to the Control Room.
 - g) In the Object properties table, verify the Control Type is TABLE.
If it is not, click **Recapture object**.
 - h) From the Action drop-down list, select **Get table**.
 - i) In the **Assign output to variable** field, create the `tLanguages` table variable.
4. Specify the file in which to save the data.
- a) Double-click or drag the **Data Table > Write to file** action.
 - b) From the **Data table name** list, select **tLanguages**.
 - c) Provide a file path to create a CSV file.
For example, `C:\Users\\Desktop\LanguagesTable.csv`.
 - d) Select the **Create folders/files if it doesn't exist** option.
 - e) Select to overwrite the existing file.
5. Specify the file that holds the extracted data.
- a) Double-click or drag the **CSV/TXT > Open** action.
 - b) Provide the file path to the file specified in step 4.
 - c) Select the **Contains header** option to exclude the first row.
6. Iterate though each row of the file.
- a) Double-click or drag the **Loop** action.
 - b) Select the **For each row in CSV/TXT** iterator.

- c) In the **Assign the current row to this variable** field, create the variable `rCurrentRow`.
7. Specify the data to populate the Bot Insight dashboard.
 - a) Double-click or drag the **Analyze > Open** action.
 - b) Double-click or drag the **String > Assign** action.
 - c) Enter `$rCurrentRow[0]$` as the source string.
Press F2 to open the variables menu.
 - d) In the **Select destination string variable** field, create the variable `sLanguage`.
 - e) Double-click or drag the **String > Replace** action.
The extracted data uses commas to separate digits. You must remove the commas before you can convert the string to a number data type to use in Bot Insight.
 - f) Enter `$rCurrentRow[1]$` as the source string.
Press F2 to open the variables menu.
 - g) Enter `,` in the **Find string** field.
 - h) Select the **Not a regular expression** option.
 - i) In the **Replace with** field, enter `$sNull$`.
 - j) In the **Assign the output row to variable** field, create the variable `sPopulation`.
 - k) Double-click or drag the **String > To number** action.
 - l) Enter the `$sPopulation$` variable.
 - m) In the **Assign the output row to variable** field, create the variable `nPopulation`.
 - n) Double-click or drag the **Analyze > Close** action.
 - o) Select the following variables:
 - **sLanguage**
 - **nPopulation**
8. Click **Save** and then **Run**.
9. Click **Analyze**.
The Bot Insight window appears.

Related reference

[Analyze package](#) on page 2310

Use the actions in the **Analyze** package to specify the actions and variables to use in the Bot Insight dashboard and widgets. The **Analyze** package enables you to perform transactional analytics for the data that is logged by the variables when the bot runs.

[Browser package](#) on page 2348

The **Browser** package contains actions that enable you to download files, find broken links, and launch a website. This package supports Google Chrome, Chromium-based Microsoft Edge, and Internet Explorer browsers.

[Recorder package](#) on page 2798

Recorder package captures a series of tasks in a process and then automates them. You can automate your business applications (for example, desktop, Web, SAP, and Java applications) using the Recorder to capture actions performed on application objects such as a text box, button, table, radio button, combo box, and list view.

[Data Table package](#) on page 2365

The Data Table package contains actions that enable you to perform various operations on the values of table variables. Use these actions to join or merge content, search for specific values, insert rows and columns, remove duplicate rows, and write values to a file.

[CSV/TXT package](#) on page 2362

The **CSV/TXT** package contains actions that enable you to open a CSV or text file, read data from that file, and assign the data to a Table variable. This package supports files encoded in ANSI, Unicode, UTF-8, or Windows-1251, and can process up to one million records.

[Loop package](#) on page 2679

Use the Loop package to run a sequence of actions repeatedly for a specific number of times or until a specific condition is met.

Example of using multiple analyze actions in a task

Build a bot that uses multiple **Open** and **Close** Analyze actions in a task to analyze and compare the sales data for each quarter of XYZ Company, and create visualizations in Bot Insight.

Before you start building the bot, create the following data set on your desktop in the .csv file format.

PRODUCT	COUNT	QUANTIT	SALES_C	QUANTIT	SALES_C	QUANTIT	SALES_C	QUANTIT	SALES_C	QTR4

1. Create a bot.
 - a) Log in to the Control Room as a Bot Creator.
 - b) On the left pane, click **Automation**.
A list of available bots and forms is displayed.
 - c) Click **Create new > Bot**.
 - d) Click **Create and edit**.

2. Open the XYZ_sales_data.csv file that you created.
 - a) Double-click or drag the **CSV/TXT > Open** action.
 - b) In the **Session name** field, enter `Session 1`.
 - c) Provide the file path to XYZ_company_sales_data.csv.
 - d) Select the **Contains header** option to exclude the first row.

3. Create a **Record** variable as Row by using the **Create variable** icon.
The **Record** variable holds all the values for one row. With each iteration of the loop, the bot retrieves the values of the next row and stores them in the **Record** variable, overwriting the values from the previous row.

4. To retrieve the values in the cells from each row in the XYZ_company_sales_data.csv file, use a **Loop** action.
 - a) Select **For each row in CSV/TXT iterator**.
 - b) In the **Session name** field, enter `Session 1`.
 - c) In the **Assign the current row to this variable** field, select the Row variable that you created.

5. Create the following variables for four quarters by using the **Create variable** icon at the top of the **Variables** menu.
 - PRODUCTCODE
 - PRODUCTLINE
 - COUNTRY
 - QUANTITYORDERED_QTR1
 - SALES_QTR1

- QUANTITYORDERED_QTR2
- SALES_QTR2
- QUANTITYORDERED_QTR3
- SALES_QTR3
- QUANTITYORDERED_QTR4
- SALES_QTR4

6. Specify the data to populate on the Bot Insight business dashboard.

- a) Double-click or drag the **Analyze > Open** action.

Note: Ensure that you insert the **Analyze Open** and **Close** actions inside the **Loop** action to analyze and capture the data from each row in the Bot Insight dashboard.

- b) Double-click or drag the **String > Assign** action.

Press F2 to open the variables menu.

- c) Choose the Row variable from the drop-down list.

- d) Enter PRODUCTCODE and click **Yes, insert**.

- e) In the **Select destination string variable** field, choose the PRODUCTCODE variable.

To assign string variables for PRODUCTLINE and COUNTRY, repeat [Step 6b](#) through [Step 6e](#).

- f) Double-click or drag the **Number > Assign** action.

Press F2 to open the variables menu.

- g) Choose the row variable from the drop-down list.

- h) Enter QUANTITYORDERED_QTR1 and click **Yes, insert**.

- i) In the **Select destination string variable** field, choose the QUANTITYORDERED_QTR1 variable.

To assign number variables for SALES_QTR1, QUANTITYORDERED_QTR2, SALES_QTR2, QUANTITYORDERED_QTR3, SALES_QTR3, QUANTITYORDERED_QTR4, and SALES_QTR4, repeat [Step 6f](#) through [Step 6i](#).

- j) Double-click or drag the **Analyze > Close** action.

- k) Enter the **Transaction** name as `Quarters 1 and 2`.

- l) Select the following transactional variables in the **Close** action:

- PRODUCTCODE
- PRODUCTLINE
- COUNTRY
- QUANTITYORDERED_QTR1
- SALES_QTR1
- QUANTITYORDERED_QTR2
- SALES_QTR2

- m) Double-click or drag the **Analyze > Open** action.

- n) Double-click or drag the **Analyze > Close** action.

- o) Enter the **Transaction** name as `Quarters 3 and 4`.

- p) Select the following transactional variables in the **Close** action:

- PRODUCTCODE
- PRODUCTLINE
- COUNTRY
- QUANTITYORDERED_QTR3
- SALES_QTR3
- QUANTITYORDERED_QTR4
- SALES_QTR4

7. Click **Save** and then **Run**.

8. Click **Analyze Task Bot**.

The Bot Insight business dashboard appears.

9. Select the **Preview** option.

The sales data is displayed as follows:

Task Name:XYZ company sales data analysis
Transaction Name: Quarter 1 and 2 Total Records: 13

Example of updating default package version across bots

This example shows how to perform a bulk update of multiple bots in the Control Room repository and use the default version of the Excel advanced and Message Box packages.

To update bots to the default package version, ensure you have the View packages permission and the permission to edit bots .

This example shows how you can update all the bots in a public repository that use the Excel advanced and Message Box packages to their default versions with one action.

1. To update all the bots in the public repository that use Excel advanced and Message Box packages to default version, perform these steps:

- a) Navigate to **Administration > Bot update**.
- b) Click the **Update Bots** drop-down and click **Package Version**.
- c) On the **Update - Package Version > Settings** page, search and select the Excel advanced and Message Box packages.
- d) Click the right arrow (→) to add the Excel advanced and Message Box packages to the selection.
- e) In the selection list, select the Excel advanced and Message Box packages and click **Next**.
- f) From the list of available bots, select the required bots for which you want to update the package version.
- g) Click the right arrow (→) to add your selection, select the bots from the selection list, and click **Next**.
- h) Review the selected bots and dependencies that you selected for the update and click **Update-Package Version**.

The bots are checked out to set the package default versions for the Excel advanced and Message Box packages.

2. On the **Bot update list** page, click the three dots icon next to the required update and click **View update bot details** to view a detailed report.
3. Navigate to **Administration > Audit log**.
4. On the **Audit log** page, search by event type and select the **Update default package** value. You can view information about status, name, start and end time, duration required for the update, the number of completed, failed, skipped, and total items with last modified time, and user details (such as username) who initiated the package update.
 - a) Click the three dots icon next to the required event and click **View event details**.

Event details:

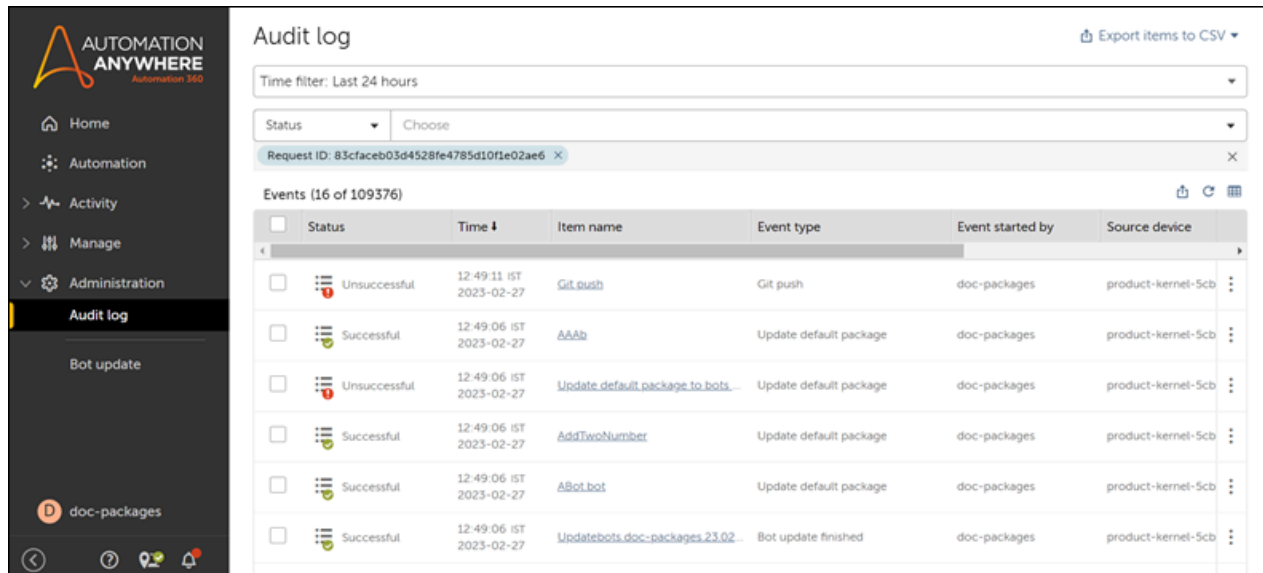

- **Status:** Successful
- **Item name:** AAAb
- **Event started by:** doc-packages
- **Time:** 12:49:06IST2023-02-27
- **Object type:** Event
- **Event type:** Update default package
- **Source device:** product-kernel-5cbc499957-1n4s8
- **Source:** Control Room
- **Request ID:** 83cfaceb03d4528fe4785d10f1e02ae6

Update default package details:

- **Request name:** Updatebots.doc-packages.23.02.27.12.18.02
- **Bot path:** Bots\AAAb
- **What changed?:** Package version
- **Package name:** MessageBox
- **Old package version:** 2.1.0-20210118-185321
- **Target package version:** 6.14.0-20221221-171419, 3.5.0-20221223-065722
- **Old bot version:** 1
- **New bot version:** 2

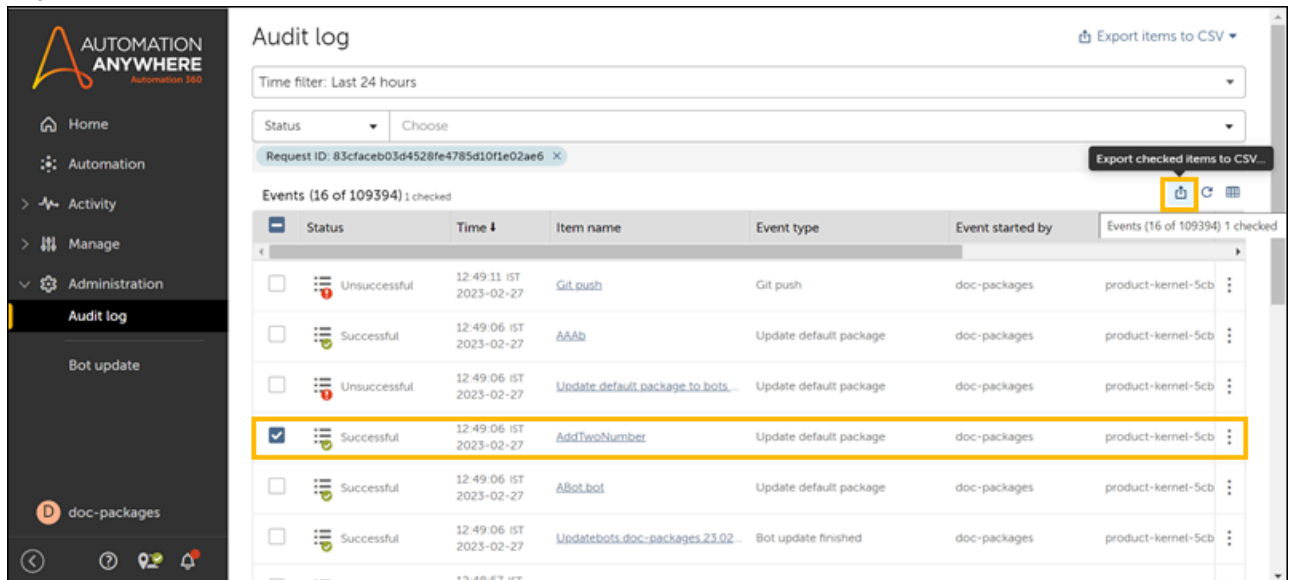

- b) Copy the **Request ID** , for example, 83cfaceb03d4528fe4785d10f1e02ae6 from the **Update default package** page.
- c) On the **Audit log** page, search by filter **Request ID** and enter the value 83cfaceb03d4528fe4785d10f1e02ae6.

The **Audit log** page displays all the bots that are either successfully updated or those that failed the update process as shown in the following image:

- d) Click any bot, for example, **AddTwoNumber**, to view the [Update default package details](#).

5. Select the required event from the **Audit log** page, for example, **AddTwoNumber**, and click **Export checked items to CSV** to download the audit data to a CSV file.

Example of using remote function call in SAP

This example describes how to build a bot that will create a document in SAP using the remote function call method.

Download the SAP Java connector package and DLL from the SAP website.

1. Open a new bot:
 - a) On the left panel, click **Automation**.
 - b) Click **Create new > Bot**.
 - c) In the **Create Task Bot** window, enter a bot name.
 - d) Click **Create and edit**.

2. Establish a connection with the SAP application using the **Connect** action.
 - a) In the **SAP BAPI Session** field, enter `Default`.
 - b) Select the **Desktop** option, then browse and select the SAP Java connector package available on your device.
Example: `F:\SAP \SAP JCo 3.1.3\Microsoft Windows and Windows Server \64-bit\sapjco3.jar`
 - c) Select the **Desktop** option, then browse and select the SAP Java connector DLL available on your device.
Example: `F:\SAP \SAP JCo 3.1.3\Microsoft Windows and Windows Server \64-bit\sapjco3.dll`
 - d) Select the **Group/Server** option as the connection type.
 - e) Select **Insecure string** and enter `AWINAAW012.bcone.com` to specify the hostname for the SAP message server.
 - f) Enter `AWINAAW012.bcone.com` in the **Gateway host** field to connect to the server.
 - g) Enter the following values:

Field	Value
Logon group	Public
System number	01
SAP instance system ID	AAI
Client number	800
Logon language code	EN
Router string	/H/115.112.148.66/S/3299

- h) Select **Insecure string** and enter `ISR3` to specify the username you want to use to connect to the SAP server.
 - i) Select **Insecure string** and enter **Automation@123** to specify the password you want to use to connect to the SAP server.

3. Use the **Create function** action to create a function for the SAP BAPI function.

- a) Create an alias for an SAP BAPI function and save it with an alias name.
- b) In the **Session name** field, enter `Default`.
- c) In the **Function alias name** field, enter `BAPI_Post`.
- d) In the **BAPI name field**, enter `BAPI_ACC_DOCUMENT_POST`.

Note: The SAP BAPI function name and other parameters are specific to the customer environment while creating the Automation 360 bot.

4. To create `BAPI_ACC_DOCUMENT_POST` in SAP, you must first create a structure and tables. Select **Get structure** to obtain data from a structure using the function alias.
 - a) In the **BAPI function alias** field, enter `BAPI_POST` (the alias you provided for SAP BAPI function using the **Create function** action).
 - b) In the **Structure name** field, enter `DOCUMENTHEADER` (the name of the structure from which you want to get data).
 - c) In the **SAP BAPI session** field, enter `Default` (the session name you used to connect to the SAP application in the **Connect** action).
 - d) Select the **Alias** option to save the data retrieved from the structure and enter `Doc` in the **Create structure alias** field.
5. Select the **Get table** action to get tabular data from a table using the function alias.
 - a) In the **BAPI function alias** field, enter `BAPI_Post` (the alias you provided for the SAP BAPI function using the **Create function** action).
 - b) In the **Table name** field, enter `ACCOUNTGL` (the name of the table from which you want to obtain data).
 - c) In the **SAP BAPI session** field, enter `Default` (the session name you used to connect to the SAP application in the **Connect** action).
 - d) Select the **Alias** option to save the data retrieved from the table and enter `GL` in the **Create table alias** field.
6. Repeat [step 5](#). In step 5(b), enter the value `CURRENCYAMOUNT` in the **Table name field** and in step 5(d) enter the value `Currency` in the **Create table alias** field.
7. Select the **Set field value** action to set data into the empty structure and table created previously.
 - a) In the **BAPI function alias** field, enter `BAPI_Post`.
 - b) From the **Source** field, select **Structure**.
 - c) Enter `DOC` in the **Structure alias** field.
 - d) In the **Field name** field, enter `USERNAME` (the name of the field in which you want to set data).
 - e) In the **Field value** field, enter `sy-uname` (the value that you want to set).
 - f) In the **SAP BAPI session** field, enter `Default`.
8. Repeat [step 7](#) seven times and input the same values as you previously entered in steps 7(a), 7(b), 7(c), and 7(f). Enter the following values for steps 7(d) and 7(e).

Field name	Field value
BUS_ACT	RFBU
HEADER_TXT	TEST BOC BAPI POSTING
COMP_CODE	1000
DOC_DATE	20210127
PSTNG_DATE	20210127
DOC_TYPE	SA
FIS_PERIOD	00

9. Select the **Get structure** action.
 - a) In the **BAPI function alias** field, enter BAPI_POST.
 - b) In the **Structure name** field, enter DOCUMENTHEADER.
 - c) In the **SAP BAPI session** field, enter Default.
 - d) Select the **Variable** option to store the data retrieved from the structure in a table variable. Create table variable Sap-Bapi-Table.

10. Double-click or drag the Data table > **Write to file** action.
 - a) Select the Table variable **Sap-Bapi-Table** that contains the data to write from the Data table name list.
 - b) Specify the location of the file in which to write the data in the **Enter file name** field. For example, D:/user defined/My Desktop/SAP Test/DOCUMENTHEADER.csv.
 - c) Select the **Create folders/files if it doesn't exist** check box.
 - d) Select the **Override existing file** option when writing data in an existing file.
 - e) Select the **new line** option from the **Row delimiter** field.
 - f) Select the **comma** option from the **Column delimiter** field.
 - g) Select the **ANSI** option from the **Encoding list**.

11. Double-click or drag the **Set field value** action to set data into table.
 - a) In the **BAPI function alias** field, enter BAPI_POST.
 - b) From the **Source** field, select **Table**.
 - c) Enter GL in the **Table alias** field.
 - d) In the **Field name** field, enter ITEMNO_ACC (the name of the field in which you want to set data).
 - e) In the **Field value** field, enter 2 (the value that you want to set).
 - f) In the **SAP BAPI session** field, enter **Default** (the session name you used to connect to the SAP application in the **Connect** action).

12. Repeat [step 11](#), seven times to set data into a table.

While setting values in the table, retain the same value as you previously entered in steps 11(a), 11(b), 11(c), and 11(f). Change the following values for steps 11(d) and 11(e):

Field value	Field name
GL_ACCOUNT	0000078310
PSTNG_DATE	20210127
ITEM_TEXT	TEST POSTING DEBIT ITEM
QUANTITY	1000
BASE_UOM	EA
COMP_CODE	1000
DOC_TYPE	SA

13. Select the **Set value** field action.
- In the **BAPI function alias** field, enter BAPI_POST.
 - From the **Source** field, select **Table**.
 - Enter GL in the **Table alias** field.
 - Select the **Create new row** check box to enter data in the next row.
 - In the **Field name** field, enter ITEMNO_ACC (the name of the field in which you want to set data).
 - In the **Field value** field, enter 1 (the value that you want to set).
 - In the **SAP BAPI session** field, enter **Default** (the session name you used to connect to the SAP application in the **Connect** action).
14. Select the **Get table** action.
- In the **BAPI function alias** field, enter BAPI_POST.
 - In the **Table name** field, enter ACCOUNTGL.
 - In the **SAP BAPI session** field, enter Default.
 - Select the **Variable** option to store the data retrieved from the table in a table variable. Create table variable Sap-Bapi-Table.
15. Double-click or drag the Data table > **Write to file** option.
- Select the Table variable **Sap-Bapi-Table** that contains the data to write from the **Data table name** list.
 - Specify the location of the file in which to write the data in the **Enter file name** field. For example, D:/user defined /My Desktop/SAP Test/ACCOUNTGL.csv.
 - Select the **Create folders/files if it doesn't exist** check box.
 - Select the **Override existing file** option when writing data in an existing file.
 - Select the **new line** option from the **Row delimiter** field.
 - Select the **comma** option from the **Column delimiter** field.
 - Select the **ANSI** option from the **Encoding list**.
16. Double-click or drag the **Set field value** action to set data into a table.
- In the **BAPI function alias** field, enter BAPI_POST.

- b) From the **Source** field, select **Table**.
- c) Enter CURRENCY in the **Table alias** field.
- d) In the **Field name** field, enter ITEMNO_ACC (the name of the field in which you want to set data).
- e) In the **Field value** field, enter 2 (the value that you want to set).
- f) In the **SAP BAPI session** field, enter Default (the session name you used to connect to the SAP application in the **Connect** action).

17. Repeat [step 16](#), seven times to set data into a table.

While setting values in the table, retain the same value as you previously entered in steps 16(a), 16(b), 16(c), and 16(f). Change the following values for steps 16(d) and 16(e):

Field name	Field value
CURRENCY	USD
AMT_DOCCUR	-2000
ITEMNO_ACC	1
CURRENCY	USD (repeated) line 43
AMT_DOCCUR	2000

- 18. Repeat [step 14](#) and enter CURRENCYAMOUNT in the **Table name** field.
- 19. Repeat [step 15](#) and specify the location of the file, for example D:/user defined /My Desktop/SAP Test/CURRENCYAMOUNT.csv.
- 20. Select the **Run function** action to run the SAP BAPI function.
 - a) In the **BAPI function alias** field, enter BAPI_POST.
 - b) Select the **End sequence** option to mark the end of a process and the **Commit transaction** option to commit the changes made during the process.
 - c) In the **SAP BAPI session** field, enter Default.
- 21. Select the **Get table** action.
 - a) In the **BAPI function alias** field, enter BAPI_POST.
 - b) In the **Table name** field, enter RETURN.
 - c) In the **SAP BAPI session** field, enter Default.
 - d) Select the **Variable** option to store the data retrieved from the table in a table variable. Create table variable Sap-Bapi-Table.
- 22. Repeat [step 15](#) and specify the location of the file, for example D:/user defined /My Desktop/SAP Test/Return.csv.
- 23. Select the **Get field value** action to obtain data of a specified field from a function.
 - a) In the **BAPI function alias** field, enter BAPI_POST.
 - b) Select the **Function** tab from **Source** field.
 - c) In the **Field name** field, enter OBJ_KEY.
 - d) In the **SAP BAPI session** field, enter Default.

- e) Select Prompt-Assignment in the **Save the output to a variable** field.
24. Double-click or drag the **Message box** action.
 - a) Enter **Automation Anywhere Enterprise Client** in the **Enter the message box window title** field.
 - b) Enter **\$Prompt-Assignment\$**.
 - c) Enter 30 in the **Scroll bar after lines** field to show a scroll bar.
 25. Repeat [step 23](#) and [step 24](#) (In step 23(c), enter the value OBJ_SYS).
 26. Repeat [step 23](#) and [step 24](#) (In step 23(c), enter the value OBJ_TYPE).
 27. Click **Save** and **Run**.

Example of using JSON package actions in a bot

Build a bot that runs a JSON script with multiple records. In this example, we use a JSON file that contains a list of feeds from a blog, and the bot extracts the required information from the JSON file and prints it to a message box.

To run JSON script from Automation 360, you must already have the JSON data stored either as a variable or a file (.json, .txt format) on your desktop. The following screenshot displays the structure of a JSON object as a sample.

```
{
  "feeds": [
    {
      "id": 1090,
      "title": "Amsterdam Beaches",
      "description": "It's true that few people think of the Netherlands when planning a beach holiday. But whether you're just visiting or lucky enough to call this iconic city home, there are plenty of great beaches to enjoy in Amsterdam",
      "location": "Kloveniersburgwal 1, 1012 CW Amsterdam, Netherlands",
      "lng": 0,
      "lat": 0,
      "userId": 3043,
      "name": "Ritu singh",
      "isdeleted": false,
      "profilePicture": "/Images/userimageicon.png",
      "videoUrl": null,
      "images": null,
      "mediatype": 0,
      "imagePaths": null,
      "feedsComment": null,
      "commentCount": 3,
      "multiMedia": [
        {
          "id": 2157,
          "name": "beach of amsterdam.PNG",
          "description": null,
          "url": "feedsmedia/3043/c5522956-4ab5-408e-b540-16a8c90af9b0.PNG",
```

```
        "mediatype": 1,  
        "likeCount": 0,  
        "place": null,  
        "createAt": "0001-01-01T00:00:00"  
    },  
    ],  
    "likeDislike": {  
        "likes": 2,  
        "dislikes": 1,  
        "userAction": 2  
    },  
    "createdAt": "2019-12-26T07:08:38.4659686",  
    "code": 0,  
    "msg": null  
},  
],  
"totalFeed": 125  
}
```

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create New > Bot**.
 - c) Provide a name for the bot: `JsonBot`.
 - d) Click **Create and Edit**.

2. Start a JSON session by using the **JSON > Start session** action.
 - a) From the **Actions** pane, double-click or drag the **JSON > Start session** action.
 - b) In the **Data Source** field, choose **File** and select the **Desktop file** file type. Click **Browse** to find your JSON file, for example, `D:\userdefined\My Downloads\Sample Json with 200 Records.json`.
 - c) To create a JSON session, from **Json object session**, select **Local session** and enter **Default** as the session name.

3. Create a variable: `SampleString`
 - **Type:** `String`
 - **Name:** `SampleString`

4. Retrieve the value of the total number of feeds from the JSON script by using the **JSON > Get node value** action.
 - a) From the **Actions** pane, double-click or drag the **JSON > Get node value** action.
 - b) In the **JSON node key or path** field, enter `totalFeed`.
 - c) In the **Session name** field, enter `Default`.
 - d) In the **Save the outcome to a variable** field, select `SampleString`.
 - e) To print the value of `totalFeed`, double-click or drag the **Message box** action.
 - f) To open the list of your variables, in the **Enter the message to display** field, press `F2`, and then select `SampleString`.

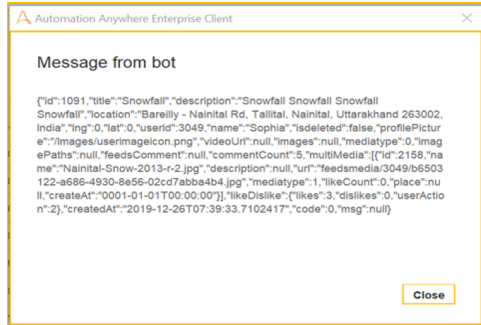

- g) Click **Yes, insert**.

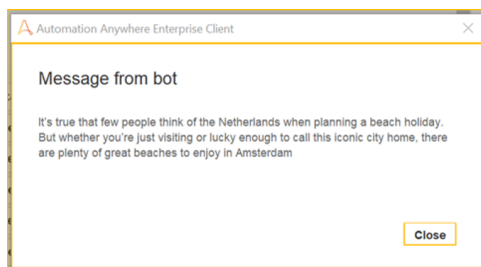

5. To retrieve any specific value from 125 feeds, perform the following steps.
- From the **Actions** pane, double-click or drag the **JSON > Get node value** action.
 - In the **JSON node key or path** field, enter `feeds[52].title`.
 - In the **Session name** field, enter `Default`.
 - In the **Save the outcome to a variable** field, select `SampleString`.
 - To print the value of `feeds[52].title`, double-click or drag the **Message box** action.
 - To open the list of your variables, in the **Enter the message to display** field, press F2, and then select `SampleString`.
 - Click **Yes, insert**.

6. Create a variable: `StringList`
- Type:** `List`
 - Subtype:** `String`
 - Name:** `StringList`
7. To retrieve the list of child nodes from a node path, use the **JSON > Get node list** action.
- From the **Actions** pane, double-click or drag the **JSON > Get node list** action.
 - In the **JSON node key or path** field, enter `feeds`.
 - In the **Session name** field, enter `Default`.
 - In the **Save the outcome to a variable** field, select `StringList`.
 - To print all the child nodes under the `feed 51` object, double-click or drag the **Message box** action.
 - To open the list of your variables, in the **Enter the message to display** field, press F2, and then select `StringList[51]`.
 - Click **Yes, insert**.

8. To close a JSON session, use **End session**. In the **Session name** field, enter `Default`.
9. Click **Save** and then click **Run**.
10. Start a new JSON session.
 - a) From the **Actions** pane, double-click or drag the **JSON > Start session** action. In the **Data Source** field, select **Text** and enter `StringList [52]`.
 - b) From **Json object session**, select **Local session** and enter `Default 1` as the session name.
11. To retrieve the value from a specific node, use **JSON > Get node value**.
 - a) From the **Actions** pane, double-click or drag the **JSON > Get node value** action.
 - b) In the **JSON node key or path** field, enter `description`.
 - c) In the **Session name** field, enter `Default 1`.
 - d) In the **Save the outcome to a variable** field, select `SampleString`.
 - e) To print the value of the `description` node, double-click or drag the **Message box** action.
 - f) To open the list of your variables, in the **Enter the message to display** field, press F2, and then select `SampleString`.
 - g) Click **Yes, insert**.

12. To close the JSON session, use **End session**. In the **Session name** field, enter `Default 1`.
13. Click **Save** and the click **Run**.
You can further perform operations to extract the required information from the JSON feed and use the extracted values in your bot. To extract the name value from feed 50 through 60, perform the following steps.
14. Create a variable: `ListItem`
 - **Type:** `String`
 - **Name:** `ListItem`

15. To process each item in the list, use the **Loop** action.
- Double-click or drag the **Loop** action.
 - Select the **For each item in the list** iterator.
 - In the **List** field, select `StringList`.
 - Choose the **Range** option and for the following fields, enter the values provided:
 - From Index:** 50
 - To index:** 60
 - In the **Assign the current value to variable** field, select `ListItem`.
16. Start a new JSON session.
- From the **Actions** pane, double-click or drag the **JSON > Start session** action.
 - In the **Data Source** field, select **Text** and enter `ListItem`.
 - To create a JSON session, from **Json object session**, select **Local session** and enter `Default 2` as the session name.
17. To retrieve the value from a specific node, use the **JSON > Get node value** action .
- From the **Actions** pane, double-click or drag the **JSON > Get node value** action.
 - In the **JSON node key or path** field, enter `name`.
 - In the **Session name** field, enter `Default 2`.
 - In the **Save the outcome to a variable** field, select `SampleString`.
 - To print the value of the `name` node, double-click or drag the **Message box** action.
 - To open the list of your variables, in the **Enter the message to display** field, press `F2` , and then select `SampleString`.
 - Click **Yes, insert**.
18. Click **Save** and then click **Run**.
The name values retrieved from the feeds 50 through 60 are as follows:

Feeds (object)	Name
50	Ashish
51	Sophia
52	Ritu
53	Shivam
54	Navya
55	Faiz
56	Martin
57	Shweta
58	Jagjit
59	Mark

Feeds (object)	Name
60	Sophia

Example using Email actions in a bot

In this example, we use email actions to perform email-related operations using Outlook Client.

Create a bot to perform the following tasks:

- Retrieve the total number of attachments from emails and print the result in the message box.
- Send a response to the sender and all the recipients of an email with the different subject.
- Delete and remove read emails from the Inbox.

1. Create a bot.

- a)** On the left panel, click **Automation**.
A list of available bots and forms is displayed.
- b)** Click **Create New > Bot**.
- c)** Provide a name for the bot: `Email_Operation_Bot`.
- d)** Click **Create and Edit**.

2. Use the Connect action to establish a connection with an email server.

- a)** Double-click or drag the **Email > Connect** action.
- b)** Enter `EmailSession` in the **Session name** field.
- c)** Select **Outlook** to establish a connection with Microsoft Outlook.
- d)** Enter `test@automationanywhere.com` in the **Outlook mailbox (optional)** field.

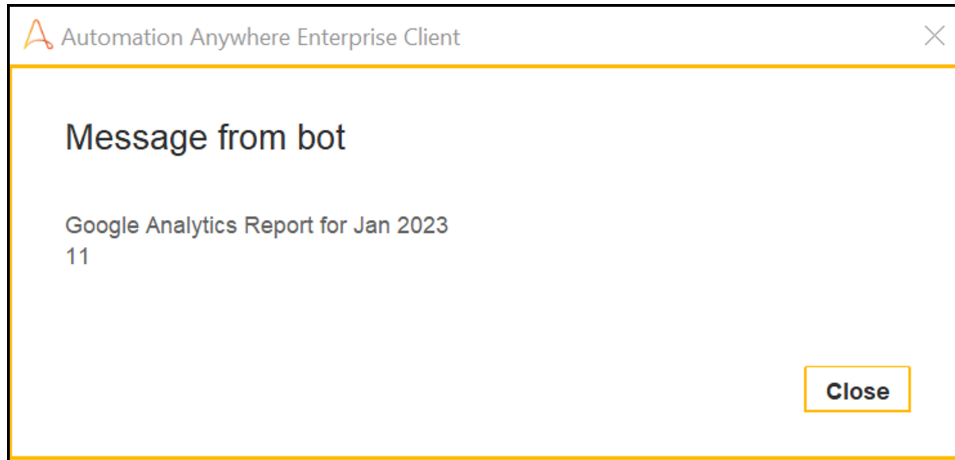

3. To process each item in the email, use the **Loop** action.

- a)** Double-click or drag the **Loop** action.
- b)** Select **For each mail in mail box** from the iterator list.
- c)** In the **Session name** field, enter `EmailSession`.
- d)** Select **All** from the **Type of emails to get** field to retrieve emails from the email server.
- e)** In the **From a specific folder (optional)** field, enter `Inbox/Analytics` folder.
- f)** Choose **HTML** option for message format.
- g)** Select **True** from the **Use local timezone** list.
- h)** In the **Assign the current value to variable (optional)** field, create `EmailDetails` as a Dictionary variable.

4. Retrieve the total number of attachments from each mail and print.

- a)** double-click or drag the **Message box** action
- b)** In the **Enter the message to display** field, enter: `$(EmailDetails{emailSubject})$$(EmailDetails{emailNoOfAttachments})$`

5. Double-click or drag the **Email > Disconnect** action. In the **Session name** field, enter `EmailSession`.
6. Click **Save** and then **Run**.
The attachment details are retrieved from the emails as follows:

emailSubject	emailNoOfattachments
Google Analytics Report for Dec 2022	12
Google Analytics Report for Nov 2022	11
Google Analytics Report for Oct 2022	9
Google Analytics Report for Aug 2022	10
Google Analytics Report for July 2022	13
Google Analytics Report for May 2022	11
Google Analytics Report for March 2022	5

7. Start a new Email session.
 - a) Double-click or drag the **Email > Connect** action.
 - b) Enter `EmailSession1` in the **Session name** field.
 - c) Select **Outlook** to establish a connection with Microsoft Outlook.
 - d) Enter `test@automationanywhere.com` in the **Outlook mailbox (optional)** field.
8. To process each item in the email, use the **Loop** action.
 - a) Double-click or drag the **Loop** action.
 - b) Select **For each mail in mail box** from the iterator list.
 - c) In the **Session name** field, enter `EmailSession1`.
 - d) Select **All** from the **Type of emails to get** field to retrieve emails from the email server.
 - e) In the **From a specific folder (optional)** field, enter `Inbox/Daily stand up meeting`.
 - f) Choose **HTML** option for message format.
 - g) Select **True** from the **Use local timezone** list.

9. Use the **Reply All** action to send a response to an email.
 - a) Enter the following email IDs. `peter_wilson@example.com`, `john.smith@example.com`, `nancy.mark@example.com`

Note: Use comma to separate the emails IDs.

 - b) In the Subject (optional) field, enter `Documentation deliverables for upcoming releases`.
 - c) Add the file attachment to the email message `release plan.xlsx`.
 - d) Select **Plain text** for the email body.
 - e) In the **Message** field, enter the following message as follows:

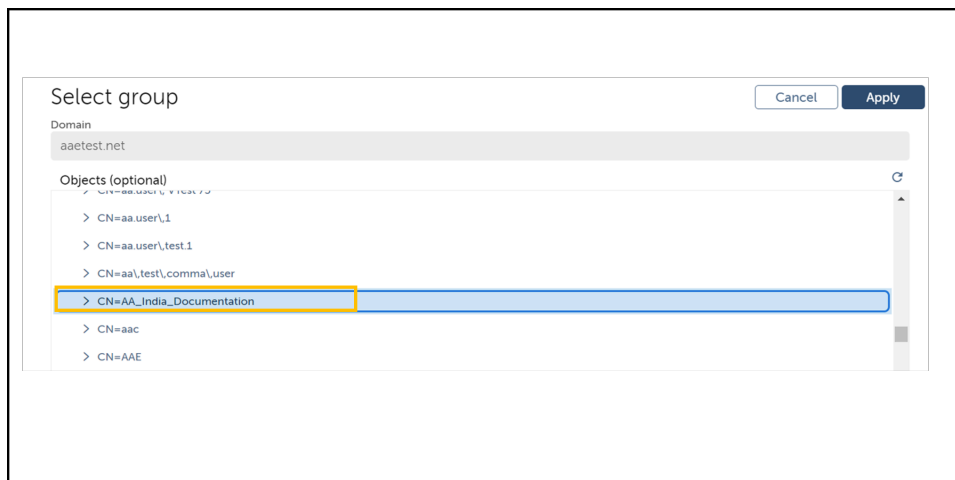

```
Hi All,  
See the attached document outlining the release plan.
```
 - f) Select the **Outlook** option from the **Send email via** list.
10. Double-click or drag the **Email > Disconnect** action. In the **Session name** field, enter `EmailSession1`.
11. Click **Save** and then **Run**
The response will be sent to the sender and all the recipients of an email.
12. Start a new Email session.
 - a) Double-click or drag the **Email > Connect** action.
 - b) Enter `EmailSession2` in the **Session name** field.
 - c) Select **Outlook** to establish a connection with Microsoft Outlook.
 - d) Enter `test@automationanywhere.com` in the **Outlook mailbox (optional)** field.
13. Use the **Delete All** action to delete all the email from the inbox.
 - a) Enter `EmailSession2` in the **Session name** field.
 - b) In the **From a specific folder (optional)** field, enter `Inbox/Backup mails`.
 - c) Select **All** from the **Type of emails to get field** to retrieve emails from the email server.
14. Double-click or drag the **Email > Disconnect** action. In the **Session name** field, enter `EmailSession2`.
15. Click **Save** and then **Run**.
The emails will be deleted from the specified folder.

Example using user account actions from Active Directory package

This example shows how to use actions to automate user account management tasks, such as: Create, Delete, Get property, Remove, Rename, and Set property.

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.

- b) Click **Create New > Bot**.
 - c) Enter a name for the bot: `Active_Directory_User Operation`.
 - d) Click **Create and Edit**.
2. Use the **Connect** action to establish a connection with an Active Directory server.
 - a) Double-click or drag the **Active Directory > Connect** action.
 - b) Enter `Default` in the **Session name** field.
 - c) Enter the LDAP URL in the **Parent path** field: `LDAP://ec2-192.168.2.60.us-east-1.compute.amazonaws.com/CN=Users,DC=aaetest,DC=net`
 - d) In the **Login username** and **Login password** fields, enter your user name and password. For example, select **Insecure string** tab and enter the following values:
 - Login username: `ksmith.doe`
 - Login password: `aa_testqwerty@123`
3. Use the **Create group** action to create a new group.
 - a) Double-click or drag the **Active Directory > Create group** action.
 - b) Enter `Default` in the **Session name** field.
 - c) Enter `AA_India_Documentation` in the **Group name** field.
 - d) Select the group scope as **Global**.
 - e) Select the group type as **Distribution**.

4. Use the **Create user** action to configure and activate a new user.
 - a) Double-click or drag the **Create user** action.
 - b) Enter `Default` in the **Session name** field.
 - c) Enter `Maverick John` in the **User name** field.
 - d) Enter `maverick.john` in the **Logon name** field.
 - e) Enter `Maverick` in the **First name** field.

- f) Select the check box **Active user** to activate the user.
5. Use the **Add user to group** action to add an existing user to a user-created group.
- a) Double-click or drag the **Add user to group** action.
 - b) Select the **Add users from server** option. To add an existing user from the server, enter these details : **Host**, **Domain**, **Username**, and **Password** in the **Connect to server** window and then click **Connect**.
 - c) Enter **AA_India_Documentation** in the **Group name** field.
 - d) Enter **Default** in the **Session name** field.

6. Use the **Set user property** action to assign a value to a user property, view the current details, and update it.
- a) Double-click or drag the **Set user property** action.
 - b) Enter **Default** in the **Session name** field.
 - c) Select the **User name** option and enter **Maverick John**.
 - d) Enter **displayName** in the **Property** field.
 - e) Enter **Mark** in the **Value** field.
7. Use the **Get user property** action to retrieve a specific property value for a user and assigns the results to a variable.
- a) Double-click or drag the **Get user property** action.
 - b) Enter **Default** in the **Session name** field.
 - c) Select the **User name** option and enter **Maverick John**.
 - d) Enter **displayName** in the **Property** field.
 - e) Select **SampleString** variable to assign value.

8. Use **Message box** action to print the values.
 - a) Double-click or drag the **Message box** action.
 - b) In the **Enter the message to display** field, select `$SampleString$`.

9. Use the **Rename user** action to rename the user logon name or the user account name.
 - a) Double-click or drag the **Rename user** action.
 - b) Enter `Default` in the **Session name** field.
 - c) Select the **User name** option and enter `Maverick John`.
 - d) Enter `Maverick John Ray` in the **New name** field.
 - e) Select the **Rename user name** option to update.

10. Use **Update user details** action to update the details of a user.
 - a) Double-click or drag the **Update user details** action.
 - b) Enter `Default` in the **Session name** field.
 - c) Select the **User name** option and enter `Maverick John`.
 - d) Enter `Maverick John Ray` in the **First name** field.

11. Use the **Disable user account** action to disable a user account.
 - a) Double-click or drag the **Disable user account** action.
 - b) Enter `Default` in the **Session name** field.
 - c) Select the **User name** option and enter `Maverick John Ray`.

12. Use the **Delete user** action to delete an existing user.
 - a) Double-click or drag the **Delete user** action.
 - b) Enter `Default` in the **Session name** field.
 - c) Select the **User name** option and enter `Maverick John Ray`.

13. Use the **Disconnect** action to close the connection with the LDAP server. In the **Session name** field, enter `Default`.
14. Click **Save** and then **Run**.

Example of using Custom column option in Data Table package

In this example, you will build a bot to read a CSV file, assign it to a data table variable, and then modify the table by adding a new column. Use the Custom column option in the Data Table package to insert columns at a specified index.

Before you start building the bot, create a file in .CSV format using the data in the following table and save it as `Data_table_input.csv`.

Name	Company	Availability
Rene	AA	FALSE
Leote	DG	FALSE
Shane	CV	FALSE

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create New > Bot**.
 - c) In the **Create Task Bot** window, enter a name for the bot: `Datatable_test`.
 - d) Accept the default folder location: `\Bots\`. To change the default bot storage location, click **Choose** and follow the prompts.
 - e) Click **Create and Edit**.
2. Open and read data from the CSV file.
 - a) Double-click or drag the **CSV/TXT > Open** action.
 - b) In the **Session name** field, enter `Session 1`.
 - c) In the **File path** field, click **Browse** to select your file.

CSV/TXT: Open

Opens a CSV/TXT file

Required bot agent version: 20.11 or above

Session name

🗨 Session 1
(x)

File path

Control Room file

Desktop file

Variable

🗨 C:\Temp\Data table_input.csv
(x)

Browse...

Required extensions: ".csv", ".txt", ".tsv"

- d) Select the **Contains header** check box.
- e) In the **Delimiter** tab, select the **Comma** check box.
- f) Double-click or drag the **CSV/TXT > Read** action.

- g) In the **Session name** field, enter `Session 1`.
 - h) In the **Assign value to the variable** field, create a table variable `TableFromCSV` to save the output.
 - i) Double-click or drag the **CSV/TXT > Close** action.
- 3. Insert a new column of data type `String` to the existing table.
 - a) Double-click or drag the **Data Table > Insert column** action.
 - b) In the **Destination table** field, select the variable `TableFromCSV`.
 - c) From the **Insert column at index** field, select **last index**.
 - d) From the **Insert column** option, select **Custom column**.
 - e) In the **Column name** field, enter **Address**.
 - f) In the **Column type** field, select the data type as **String**.
 - g) In the **Default value** field, enter `Bangalore`.
- 4. Write the new data to the CSV file.
 - a) Double-click or drag the **Data Table > Write to file** action.
 - b) In the **Data table name** field, select `TableFromCSV` variable.
 - c) In the **Enter file name** field, select the CSV file that you have saved on your desktop.
 - d) From the **When writing** field, select the **Overwrite existing file** option.
- 5. Open the CSV file to view the updated data.
 - a) Double-click or drag the **Excel advanced > Open** action.
 - b) In the **File** tab, click **Browse** to select your file.
 - c) Select the **Sheet contains a header** check box.
 - d) Select the **Read-write mode** option to enable reading and editing of the file.
 - e) Double-click or drag the **Delay > Delay** action.
 - f) Enter a delay time of 5 seconds.
- 6. Close the CSV file.
 - a) Double-click or drag the **Excel advanced > Close** action.
 - b) Select the **Save changes when closing file** option.
 - c) In the **Session name** field, select the name of the session that you used to open the CSV file.
- 7. Insert a new column of data type `DateTime` to the existing table.
 - a) Double-click or drag the **Data Table > Insert column** action.
 - b) In the **Destination table** field, select the variable `TableFromCSV`.
 - c) From the **Insert column at index** field, select **specific index** and specify the index in the text field.
 - d) From the **Insert column** option, select **Custom column**.

- e) In the **Column name** field, enter **Date of joining**.
8. Open the CSV file to view the updated data.
 - a) Double-click or drag the **Excel advanced > Open** action.
 - b) In the **File** tab, click **Browse** to select your file.
 - c) Select the **Sheet contains a header** check box.
 - d) Select the **Read-write mode** option to enable reading and editing of the file.
 - e) Double-click or drag the **Delay > Delay** action.
 - f) Enter a delay time of 5 seconds.
 9. Close the CSV file.
 - a) Double-click or drag the **Excel advanced > Close** action.
 - b) Select the **Save changes when closing file** option.
 - c) In the **Session name** field, select the name of the session that you used to open the CSV file.

Example of using a file variable

Learn to use file variables in bots. There can be instances where a bot needs to access a file multiple times based on the task it performs. You can store file references in file variables and use the file variables in bots instead of adding direct file paths.

In this example, the sample bot does the following:

- Uses a file variable to access a CSV file.
- Opens and reads data from the file using the file variable.
- Retrieves and displays the address of an employee as a message.

If you do not already have a sample CSV file with addresses, you can copy the following data to a text file and save it as a CSV file on your computer:

```
Roy, Doe, 120 Jefferson St., Riverside, IT_PROG
Shaun, McGinnis, 220 Hobo Av., Rocky Point, FI_ACCOUNT
John, Mark, 124 Jefferson St., Riverside, SA_HEAD
Sophie, Tyler, 7300 Terrace "At the Plaza" Rd., Wells, IT_PROG
Stephen, Mathew, 22 Theressia St., Troy, IT_PROG
Anne, Ross, 9th St., Lexington, IT_PROG
```

1. Create a bot.
 - a) On the left panel, click **Automation**.
A list of available bots and forms is displayed.
 - b) Click **Create New > Task Bot**.
 - c) Enter `Employee Data` as the name for the bot.
 - d) Click **Create and Edit**.
2. Create a variable named `varFile`.

- a) Click **Create variable** in the **Variables** panel.
 - b) In **Type**, select **File** as the variable type.
 - c) In **Name**, enter `varFile`.
 - d) Select **Desktop folder or file**.
 - e) In **Specific path**, click **Browse** and select the sample CSV file you have on your computer.
 - f) Click **Create**.
3. To open the CSV file using the file variable, find the **CSV/TXT** package from the **Actions** panel, and add the **Open** action to the Bot editor.
- a) In **File path**, click **Variable** and enter `$varFile$`.
 - b) Ensure that **Comma** is selected as delimiter if you are using the sample data provided in the tutorial. If your CSV file uses another delimiter, specify the delimiter.
 - c) Click **Save**.
4. To read the CSV file, find the **CSV/TXT** package from the **Actions** panel, and add the **Read** action to the Bot editor.
- a) In **Assign value to the variable**, click **(x)** to create a variable named `TableFromCSV`. The values read from the CSV file will be stored in the variable.
 - b) Click **Save**.
5. To display the address from the fourth row as a message, add the **Message Box** action to the Bot editor.
- a) In **Enter message to display**, click **(x)**.
 - b) Select the `TableFromCSV` variable.
 - c) To select the fourth row, enter 3 in **Table row index**.
 - d) To select the third column, click **Index** in **Table column**, and then enter 2. Ensure that the value entered in the **Enter message to display text** field is `$TableFromCSV[3][2]$`.
 - e) Click **Yes, insert**.
 - f) Click **Save**.
6. Run the bot.
The bot displays the address: 7300 Terrace "At the Plaza" Rd.

Example of using Custom selection option in Log variables to file action

In this example, you will use the Custom selection option to log user-defined variables to an existing log file and then modify the values of the variables and log the appended data into a file.

1. Create a bot.
 - a) On the left panel, click **Automation**.

A list of available bots and forms is displayed.

- b) Click **Create New > Task Bot**.
- c) Enter a name for the bot: `Log user defined variables`
- d) Click **Create and Edit**.

2. Create the following user-defined variables using the **Create variable (+)** icon at the top of the **Variables** menu.

Data type	Variable name	Variable value
String	Day_1	monday
String	Day_2	Tuesday
String	Day_3	Wednesday
Number	Temperature_Mon	9.3555555555555589
Number	Temperature_Tues	10.822222222222222
Number	Temperature_Wed	17.800000000000004
Datetime	Time_Mon	5/7/2023 01:15 AM
Datetime	Time_Tues	5/8/2023 01:00 AM
Datetime	Time_Wed	5/9/2023 01:00 AM
Boolean	Chances_of_rain_Mon	True
Boolean	Chances_of_rain_Tues	False
Boolean	Chances_of_rain_Wed	True

3. Double-click or drag the **Log to file > Log variables to file** action.
- a) In the Output file path field, specify the file location. For example, `D:\userdefined path\weather_forecast-data.txt`.
 - b) In the **When logging** field, select **Overwrite existing log file** option.
 - c) In the Variables to log field, select the Custom selection option and select all variables as follows:

Variables to log

By type **Custom selection**

Variables selected below, will be considered. Any variable added later will not be used

- Select all variables
- Chances_of_rain_Mon
- Chances_of_rain_Tues
- Chances_of_rain_Wed
- Day_1
- Day_2
- Day_3
- Temperature_Mon
- Temperature_Tues
- Temperature_Wed
- Time_Mon
- Time_Tues

4. Click **Save** and then **Run**.
The data is logged as follows:

```
Task bot name : \Bots\Log user defined variables
chances_of_rain_mon (Boolean) = true
chances_of_rain_tues (Boolean) = false
chances_of_rain_wed (Boolean) = true
day_1 (String) = monday
day_2 (String) = Tuesday
day_3 (String) = Wednesday
temperature_mon (Number) = 9.35555556
temperature_tues (Number) = 10.82222222
temperature_wed (Number) = 17.8
time_mon (Datetime) = 2023-05-07T01:15:00+05:30[Asia/Calcutta]
time_tues (Datetime) = 2023-05-08T01:00:00+05:30[Asia/Calcutta]
time_wed (Datetime) = 2023-05-09T01:00:00+05:30[Asia/Calcutta]
```

5. Double-click or drag the **String > Uppercase** action.
- a) In the **Source string** field, select Day_1 to insert the variable.
 - b) In the **Assign the output to variable** field, select the Day_1 variable from the drop-down.
6. Double-click or drag the **Number > Increment** action.
- a) In the **Enter number** field, select Temperature_Tues to insert the variable.
 - b) Enter 15 in the **Enter increment value** field.
 - c) In the **Assign the output to variable** field, select Temperature_Tues variable from the drop-down.
7. Double-click or drag the **Boolean > Invert** action.
- a) From the **Select the boolean variable to be inserted** field, select the True option.
 - b) In the **Assign the output to** field, select the Chances_of_rain_Wed variable from the drop-down.
8. Double-click or drag the **Log to file > Log variables to file** action.

- a) In the Output file path field, specify the file location. For example, D:\userdefined path\weather_forecast-data.txt.
- b) In the **When logging** field, select **Append to existing log file** option.
- c) Select the **Append timestamp** check box.
- d) In the **Variables to log** field, select the **Custom selection** option and select all variables as previously shown in Step 3c.

9. Click **Save** and then **Run**.

The updated data is logged with the timestamp details in the file as follows.

```
Task bot name : \Bots\Log user defined variables
chances_of_rain_mon (Boolean) = true
chances_of_rain_tues (Boolean) = false
chances_of_rain_wed (Boolean) = true
day_1 (String) = monday
day_2 (String) = Tuesday
day_3 (String) = Wednesday
temperature_mon (Number) = 9.35555556
temperature_tues (Number) = 10.82222222
temperature_wed (Number) = 17.8
time_mon (Datetime) = 2023-05-07T01:15:00+05:30[Asia/Calcutta]
time_tues (Datetime) = 2023-05-08T01:00:00+05:30[Asia/Calcutta]
time_wed (Datetime) = 2023-05-09T01:00:00+05:30[Asia/Calcutta]
-----
Logged date : 30-05-2023 14:37:35
Task bot name : \Bots\Log user defined variables
chances_of_rain_mon (Boolean) = true
chances_of_rain_tues (Boolean) = false
chances_of_rain_wed (Boolean) = false
day_1 (String) = MONDAY
day_2 (String) = Tuesday
day_3 (String) = Wednesday
samplenumber (Number) = 0
samplestring (String) =
temperature_mon (Number) = 9.35555556
temperature_tues (Number) = 25.82222222
temperature_wed (Number) = 17.8
time_mon (Datetime) = 2023-05-07T01:15:00+05:30[Asia/Calcutta]
time_tues (Datetime) = 2023-05-08T01:00:00+05:30[Asia/Calcutta]
time_wed (Datetime) = 2023-05-09T01:00:00+05:30[Asia/Calcutta]

```

Create dictionary type variables

Use Automation 360 to create dictionary type variables using different dictionary subtypes and key value type parameters.

- Ensure you have access to the Control Room.
 - You must have credentials with **AAE_Basic** permissions.
 - Your workstation must be a registered device in the Control Room.
1. Log in to the Control Room.
 2. On the left pane, click **Automation**.
A list of available and forms is displayed.
 3. Click the **Create a bot** icon.
 4. In the **Name** field, enter DictionaryMapping, and click **Create & Edit**.
 5. From the Bot editor, click **Variables** > **Create variable** (+ icon) at the top of the **Variables** menu to create four new custom dictionary variables:

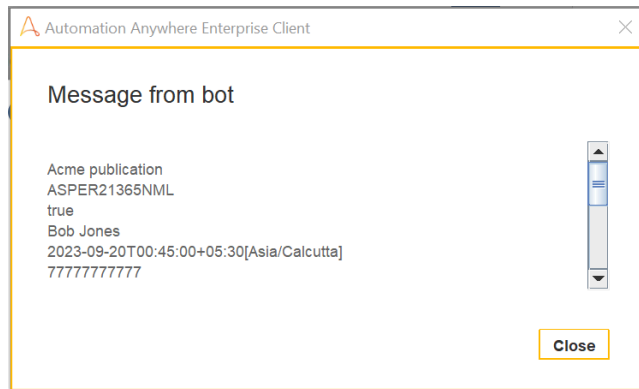

Variable type	Subtype	Variable name	Default value
Dictionary	String	Dictionary1	Key: Company name Value: Acme publication
Dictionary	String	Dictionary2	Key: Company Registration number Value: ASPER21365NML
Dictionary	Number	Dictionary3	Key: Total employees Value: 3000
Dictionary	Any	Dictionary4	<ul style="list-style-type: none"> • Type: String <ul style="list-style-type: none"> • Key: Employee name • Value: Bob Jones • Type: Datetime <ul style="list-style-type: none"> • Key: Date of Joining • Value: 9/20/2023 • Type: Boolean <ul style="list-style-type: none"> • Key: Employment type- Contractor • Value: True • Type: Number <ul style="list-style-type: none"> • Key: Phone number • Value: 7777777777

6. In the **Actions** pane, find **Message box**. In **Enter the message to display**, enter **F2**, and select the following variables:

- \$Dictionary1{"Company name"}\$
- \$Dictionary2{"Company Registration number"}\$
- \$Dictionary4{"Employment type - Contractor"}\$

- `$Dictionary4{"Employee name"}$`
- `$Dictionary4{"Date of Joining"}$`
- `$Dictionary4{"Phone number"}$`

7. Save and run the **DictionaryMapping** Task Bot.
The output is displayed as:

This section contains code examples and explanations about how to code some basic bot capabilities.

Attended and unattended automation

Automation 360 provides attended and unattended automation for users to create bots that can manage routine tasks efficiently. While users focus on critical inputs that require manual overview or approval, bots handle tasks such as gathering information across databases, validating data, or responding to chats.

Overview

Collaboration between humans and software bots is called attended automation. As attended automation requires user supervision, it is best suited for use with smaller and more fragmented tasks. However, some tasks within a business process do not change a lot over time and might not require extensive user intervention, such as collecting data or retrieving information from multiple databases. When such tasks that require little or no user judgment are configured to trigger other bots, it is called unattended automation. Unattended automation is useful to perform privileged operations, requiring elevated permissions and credentials.

Automation 360 offers a combination of attended and unattended automation for a complete automation solution with the following benefits:

- Automated integration between multiple applications or databases, reducing errors as very little user intervention is necessary.
- Access bots in real-time through an easy to use interface.
- Users can set up or change triggers to start bots based on real-time.

Watch the following video to understand attended automation:

Use Automation Co-Pilot for Business Users through your desktop to manage routine tasks such as validating data, retrieving approvals, and managing escalations through bots.

Related information

[Using bots to solve problems](#)

Automation Co-Pilot for Business Users

Automation Co-Pilot for Business Users provides a simple, front-end interface for users to execute and interact with bots and applications.

Note: Roles, permissions, and licenses may continue to reference Automation Anywhere Robotic Interface (AARI)] within the product.

Use Automation Co-Pilot for Business Users to create, run, and access end-to-end process automations across enterprises by connecting bots in the front and back offices:

- Create automations using attended and unattended bots with Automation Co-Pilot on the web that provides you a unified experience to view and organize your documents and tasks, perform actions, and gives you a process-centric approach to deliver automation.
- Access and run automations as an attended Bot Runner without logging into the Control Room with Automation Co-Pilot on the desktop. Manage routine tasks such as validating data and retrieving approvals with interactive forms, and managing escalations via bots by adding triggers.
- Access automated processes and bots from any platform with an embedded interface using Embedded Automation that can be integrated with your web application or delivered through a browser extension such as Microsoft Teams, SAP, ServiceNow, Workday, and Genesys to name a few.
- Execute bots from various third-party applications that are integrated with Automation 360 using their built-in connectors such as Salesforce, Google Workspace, Genesys, MuleSoft, ServiceNow, Workday, or SAP; and via Automation Anywhere pre-built Integration Platform as a Service (IPaaS) such as Apigee, SnapLogic, and Workato.

Why use Automation Co-Pilot

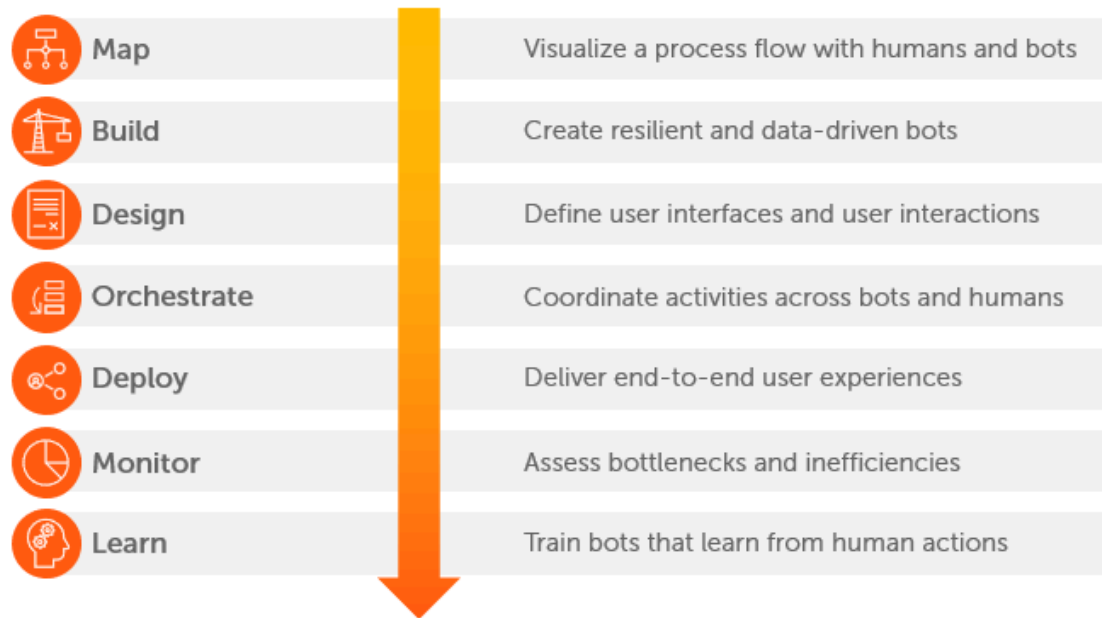

Automation Co-Pilot helps you to achieve the following goals:

- Simplify everyday tasks, such as reporting and keeping track of urgent requests.
- Collaborate easily with your team's applications and bots, thereby improving average handle time and resolution rate, which helps improve customer satisfaction.
- Speed up even the most complex requests by automating escalations and approvals.
- Accelerate return-on-investment owing to minimal investment on infrastructure, training, and set-up costs for your enterprise.

What you can do with Automation Co-Pilot

Automation Co-Pilot enables real-time communication between users and bots. By using Automation Co-Pilot to automate repetitive and time-consuming tasks, you can improve customer experience, increase employee productivity, and cut operational costs for your organization.

The following image illustrates how Automation Co-Pilot enhances automation.

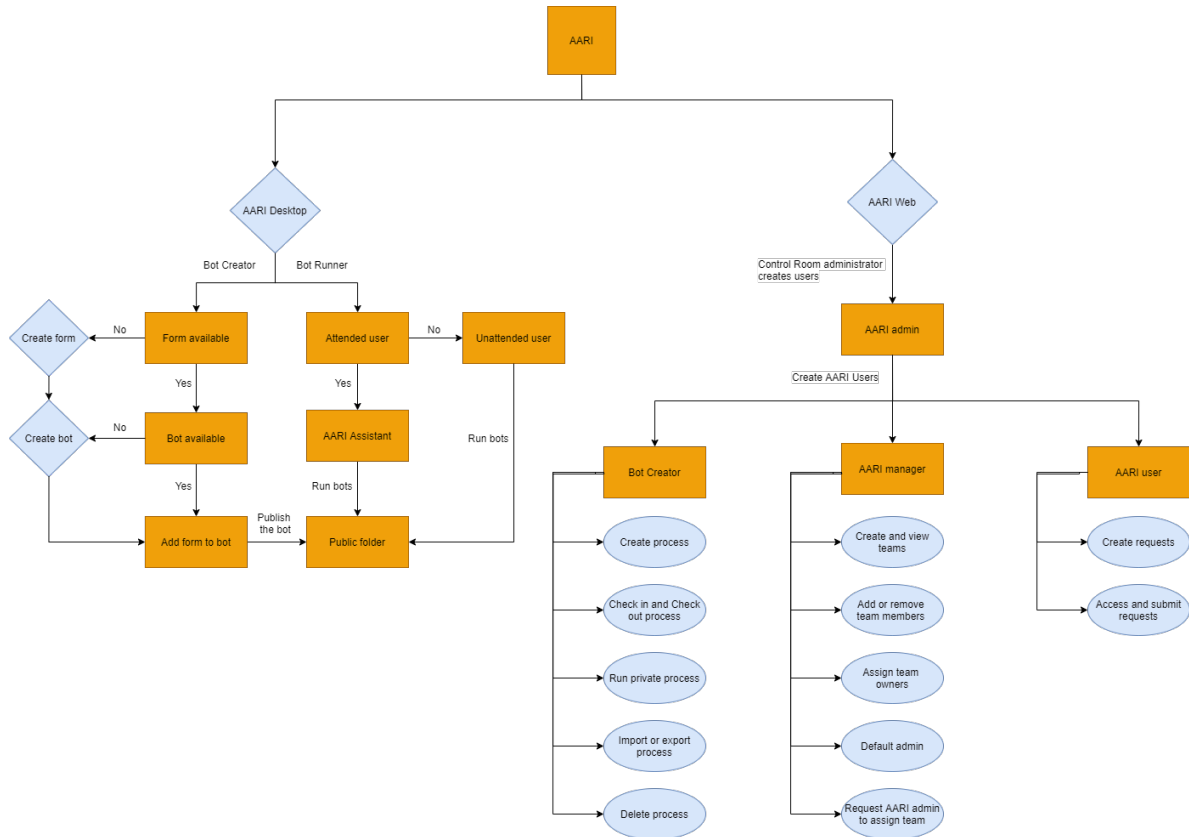

Different ways to use Automation Co-Pilot for Business Users

Automation Co-Pilot provides various interfaces that you can use to connect to business workflows at multiple touchpoints. Access Automation Co-Pilot in the following ways:

- **Web browser**
Access Automation Co-Pilot through a URL to manage front and back office functions, gathering input and approval from a single interface.
- **Desktop**
Retrieve and update data with custom forms. You can view and interact with all data from a single screen instead of switching between multiple systems.
- **Embed Automations**
Access automated processes and bots from any platform with an embedded interface. You can deliver automation everywhere you want, either integrated with your web application or delivered through a browser extension.
- **Applications**
Execute bots from common enterprise applications such as Salesforce and Google Workspace through Automation Anywhere pre-built integrations.
 - [RPA Bots for Salesforce](#)

- [RPA Bots for Google Workspace](#)

The following image illustrates the difference in the process flow between Automation Co-Pilot on desktop and on the web:

Embed automations in your application using Automation Co-Pilot for Business Users

Access automated processes and bots from any platform with an embedded interface. Automation Co-Pilot for Business Users delivers automation everywhere you want, either integrated with your web application or delivered through a browser extension.

Benefits

Bring the power of the Automation Anywhere platform directly into any cloud environment or web application, packaged in an intuitive widget interface. Automation Co-Pilot is the interface for embedded automation that empower end users with essential access to data across platforms, delivered directly to their core interactive space. This data access could be forms, applications, business history, and more. Whenever users need business data, Automation Co-Pilot ensures that it is readily available.

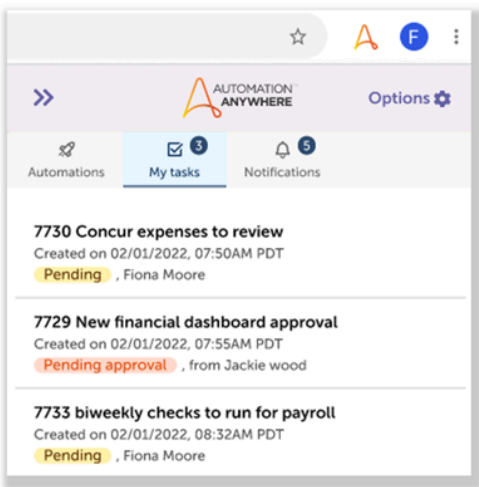

iFrame Widget
for web apps supporting customization

Embed automation in any web application

Attended, unattended and process automations

Lightweight and responsive interface

Seamless authentication with OAuth 2.0 or SAML SSO

Chrome Extension Widget
for web apps not supporting customization

With automation a click away, there is little need to keep open an additional application in your workspace. Automation can simply be embedded in the familiar space you spend the majority of time. With accessible automation, users can quickly reach out, deliver information, and keep the customer experience positive and progressive, while reducing wait times.

Capabilities of Automation Co-Pilot

There are many cases where users can leverage this ever-present access to launch automation and processes in their familiar environment. The following are a few cases where Automation Co-Pilot improves workflow with streamlining and precision:

Fetch case data from user input or from hosting data input	Access, complete, and submit forms with business data onscreen in your web application. This further empowers running attended bots that rely on source context and visual cues while executing.
Launch automation with hosting data input	While updating an account, business users can run a bot that takes a sales order number, fetches additional details as needed, and then pushes all details into the system to immediately begin billing for the sale.
Orchestrate case resolution and business workflow	Automated processes can guide agents through a complex task involving management approval, prompting and alerting team members during process phases to expedite approval, and finally enter customer and business data into a final document rendered for official record.
Automate mundane local tasks	Bots can upload sales leads or contact info from a desktop spreadsheet to web applications with one easy click.

Solutions of Automation Co-Pilot

There are two main solutions to provide your environment with Automation Co-Pilot and display an iFrame widget. The two solutions are Automation Co-Pilot using embedded widget and Automation Co-Pilot using Chrome extension.

Integrate a widget with your web application	This refers to configurations that embed our widget in web applications. End users you can access automated processes and bots without leaving the environment. The widget is composed from an HTML inline frame, or simply an iFrame widget, that can be configured and accessed in supported web browsers.
Configure an extension on Google Chrome browser	This refers to configurations that embed our interface as a side panel of the web browser. The interface is rendered by an extension for Google Chrome. End users can access automated processes and bots without leaving the web application in the browser. Extensions offers further adaptability through web page customization, such as mapping an automation to web elements, like a button. With an OAuth

2.0 connection, existing access to automation in the Automation Workspace are now shared with Automation Co-Pilot (extensions) to offer you a seamless user experience.

The AARI Admin has the key role of organizing access points for business users using Automation Co-Pilot.

Getting started

Setup of Automation Co-Pilot begins with an admin selecting configurations from Automation Co-Pilot to the desired application.

For Automation Co-Pilot using embedded widget, the iFrame widget embeds seamlessly into adjacent content of your web application. The admin must first set up and configure the iFrame widget details and then assign automation to teams by adding specific members of a team and defining the team owners and admins. After setup is completed business users can deploy automation in their web application using the iFrame widget.

Automation Co-Pilot using Chrome extension has a similar setup process, differing in the way the interface is accessed, via an extension for the Google Chrome browser. Because of this difference, a developer has to enable web components for the extension.

Similar to Integrations, the AARI Admin completes the setup and configuration of the iFrame widget. Next, a bot creator develops a web component using a **Page Editor**, assisted by a generated iFrame widget embed code. Newly created web components become visible within Automation Co-Pilot using Chrome extension for administrators to assign to teams. Assigned users will then navigate to their web application and access the components, while logged in to their Automation Workspace.

Automation Co-Pilot for Business Users using embedded widget and Chrome extension

Compare the two Automation Co-Pilot delivery methods of embedding automation to decide on the right component for your business needs.

Automation Co-Pilot is a platform for automation to assist business users with common workflows. Users can continue to automate using Automation Co-Pilot in their favorite web applications and CRM platforms, such as the ServiceNow service portal. When you use Automation Co-Pilot using embedded widget to set up your iFrame widget, you can now access Automation Co-Pilot through an embedded widget in your web application and deploy automation, all without the need to leave your environment.

Comparing components

As you explore Automation Co-Pilot using embedded widget and Automation Co-Pilot using Chrome extension, they might seem very similar. They are both solutions that provide your environment with an iFrame widget interface powered by AARI. The iFrame widget hosts automation from AARI on the web, offering the same power of automating with Automation 360.

Either Automation Co-Pilot using embedded widget or using Chrome extension can deliver a method of embedding automation. However, depending on where you aim to embed, one component might better suit your needs over the other.

Simply put, the decision to embed a widget in your environment relies on choosing one of the following methods:

- Embedded widget: Add an iFrame widget to the source code of your web application.
- Google Chrome extension: Develop custom bricks that are coded into your browser through an extension.

Consider technical specifications and styles of these components.

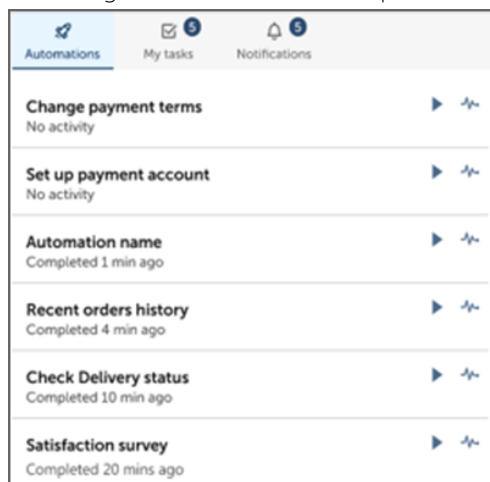

Automation Co-Pilot using embedded widget

Automation Co-Pilot using embedded widget embeds in web applications as an iFrame widget offering end-users access to automated processes and bots without leaving their environment.

Consider the following prerequisites for using Automation Co-Pilot using embedded widget:

- Automation 360 v.26 or later.
- Google Chrome, Microsoft Edge Chromium, or Apple Safari web browsers. See [Browser requirements for Automation Workspace](#) on page 1154.
- AARI licenses and fluency.
- Automation Co-Pilot on the web interface.
- Web application that supports the iFrame widget.

For further details on how to start using Automation Co-Pilot using embedded widget, click the image to navigate to the overview topic:

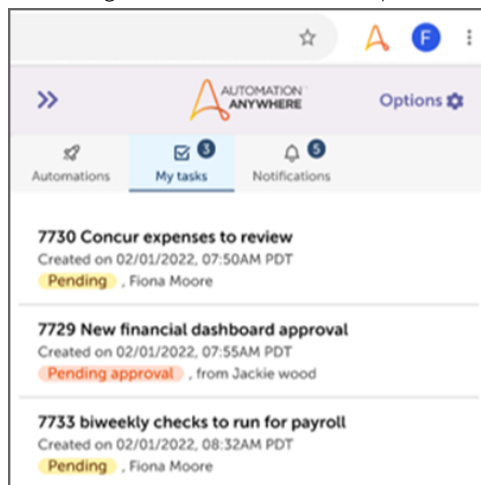

Automation Co-Pilot using Chrome extension

Automation Co-Pilot using Chrome extension relies on a Chrome extension of your web browser to embed automation. The widget appears outside the application as an Automation Anywhere stylized panel, as in the following image.

Consider the following prerequisites for using Automation Co-Pilot using Chrome extension:

- Automation 360 v.26 or later.
- Google Chrome web browser.
- AARI licenses and fluency.
- OAuth 2.0 Control Room configuration for server validation.

For further details on how to start using Automation Co-Pilot using Chrome extension, click the image to navigate to the overview topic:

Automation Co-Pilot using embedded widget overview

You can use a widget that embeds automation built on the Automation 360 platform that can be applied natively on any supported web application.

Capabilities

iFrame widget

A widget that is composed from an HTML inline frame, or simply iFrame widget, can be used as a "window" to access another website located in your current web application environment. In addition, the iFrame widget provides reliable and secure methods of quick integrations performance without the need for heavy development work, when involved with custom integrations.

For example, your current web application environment is domain 1, which can access a widget that shows a website from domain 2. These two domains exist in one shared

environment, without you navigating to a separate page or window.

iFrame widget experience on supported web applications

The Automation 360 platform can support embedding an iFrame widget on any web application that supports the iFrame technology to access external contents. Many software-as-a-service (SaaS) web applications support the iFrame widget to allow for customization in a secure environment.

Business users can add contextual workflow automations from inside their most used and preferred enterprise applications. This approach means that users need to add only minimal code to their most used web applications, which when applied can produce a rich, friendly, and more secure interactive user experience.

Actions that can be performed with iFrame widget

Business users can use iFrame widget to perform the following:

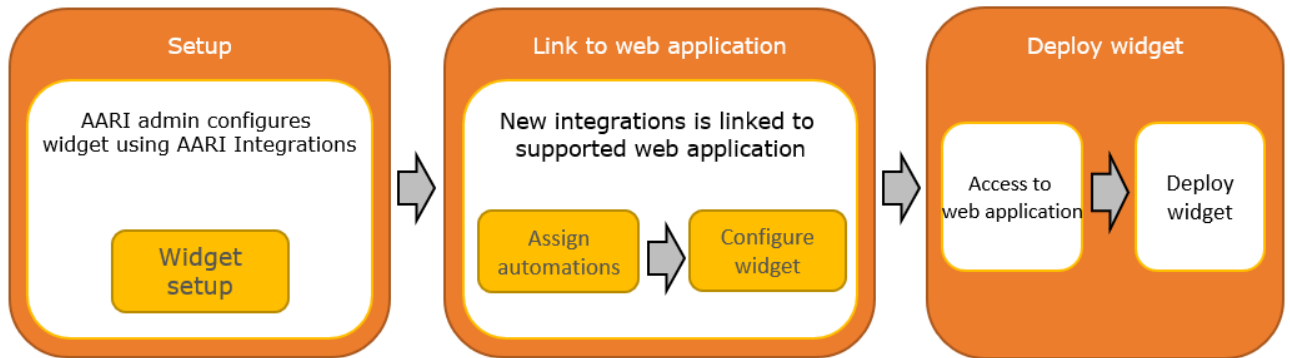

- Invoke local automations on their desktop.
- Invoke multi-step process workflows from Automation Co-Pilot requests.
- Monitor request progress to completion.
- Receive notification of pending tasks.
- Respond directly to pending tasks from iFrame widget.
- View the history of currently running or previously completed automations.

Requisites

- Ensure that you have the proper role and permissions. [Create users for Automation Co-Pilot on page 3291](#)
 - AARI license.
 - Proper roles for AARI Admin and AARI User.
- Automation 360 v.26 or later.
- Google Chrome, Microsoft Edge Chromium, or Apple Safari web browsers. See [Browser requirements for Automation Workspace](#) on page 1154.

- Automation Co-Pilot web interface.
- Web application that supports iFrame technology.

Process flow

1. Set up your iFrame widget for a web application.
2. Assign automations to a team for them to access data from the iFrame widget.
3. Configure widget settings in a web application to properly access iFrame widget.
4. Deploy the iFrame widget.

Workflow map: Click the following schematic image to view the Automation Co-Pilot using embedded widget workflow in an interactive visual

format:

1. [AARI Integrations](#)

Setup iFrame widget using Automation Co-Pilot

You can setup your iFrame widget for your supported web applications. This includes embedding a widget and configuring the iFrame widget code.

Ensure you have completed the following:

- Provided a system-created **AAE_Robotic_Interface Admin** role for the AARI Admin.
- Have access to the Automation Co-Pilot for Business Users on the web interface.

- Complete any necessary password changes to access the Automation Co-Pilot for Business Users on the web interface.

For this task, you can create new integrations and configure your iFrame widget details including access to the embed code for you to copy and use in a web application.

Important: You can only setup integrations and iFrame widget details for web applications that supports the iFrame widget. If the web application does not support the iFrame widget, refer to [Automation Co-Pilot for Business Users using embedded widget and Chrome extension](#) on page 3149.

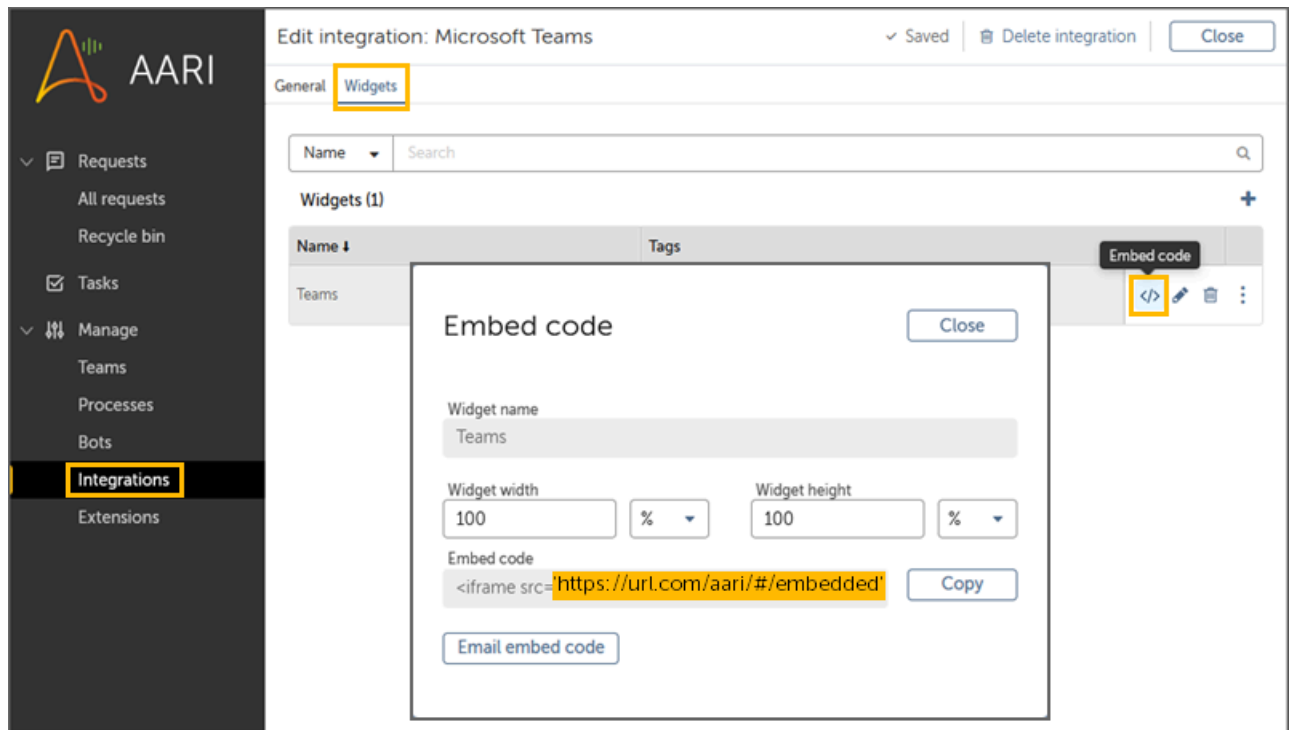

1. Log in to Automation Co-Pilot for Business Users on the web interface.
2. Navigate to **Manage > Integrations**.
The **Integrations Setup** page appears for you to setup your connection. If this is your first time accessing this page, you will see the **No Integrations** label.
3. Click **Add Integrations** to add a new integration.
4. Specify a name for the integration in the **Name** field.
You can name it **Integrations** or the name of your favorite web application to help you define the web application that you plan to embed the iFrame widget.
5. Optional: Specify a description for your integration in the **Description** field.
6. Click **Create & edit**.
Your integrations is now created and forwards you to an **Edit integration** page that you can edit your integration.
7. Navigate to the **Widgets** tab in the same page.
You can add iFrame widgets to your integration in this tab.
8. Click the plus (+) icon.
The **Add Widget** page prompts you to add a new iFrame widget to your integration.
9. Specify a name for the iFrame widget in the **Widget name** field.
10. Specify your tags in the **Filtered automations** field.
You can select existing tags from the drop-down to add to the widget. When you add tags, they display in the embedded **widget** tab on your desktop application, in the **tags** column next to the widgets. Tags allow you to filter out automations and display only a subset of automations from the entire list. This will give you the ability to call and access only the tagged automations in your embedded widget. To add a tag, see: [Configure a process](#) on page 3278.

The screenshot shows the 'Add Widget' dialog box. At the top, there are 'Close' and 'Save' buttons. The 'Widget name' field contains the text 'Case' and has a note below it stating 'Maximum 255 Characters'. Underneath is the 'Filter automations' section, which includes a dropdown menu with 'Support' and 'Account' selected, and a 'Select tags' button. Below the dropdown is a list of checkboxes for 'Support', 'Workspace', 'Account', and 'Salesforce', with 'Support' and 'Account' checked.

11. Click **Save**.
You have now successfully defined a new iFrame widget for your integration.
You can now generate an iFrame code.
12. Click the three dots (ellipses) next to the name of your iFrame widget.
 - **Embed code** option allows you to generate code for the iFrame widget.
 - **Edit** option enables you to edit the iFrame widget details.
 - **Delete** option will delete the iFrame widget.
13. Click **Embed code** option.
The **Embed code** window appears and prompts you configure the code details.
14. Specify the size of the iFrame widget width and height in the **Widget width** and **Widget height** fields, respectively.

Note: The default size of the iFrame widget width and height are **100 %**. You can change % (default) to **px** for pixels depending on your preference.

15. Click **Copy** in the **Embed code** section to copy the code.

16. Optional: Click **Email embed code** if you would like to open your local mail client to email the embed code to another individual.
You now have access to the iFrame widget code.
17. Click **Close**.
You have now successfully copied your iFrame widget code that can be used in a supported web application.
For your next steps, you can assign automations to your team, see [Assign automations to teams](#) on page 3156.

Assign automations to teams

You can configure teams to access automations and tasks for it to be accessed via Automation Co-Pilot Desktop Assistant, Automation Co-Pilot for Business Users on the web interface, and the iFrame widget embedded in other business applications.

Ensure you have completed the following:

- Provided a system-created **AAE_Robotic_Interface Admin** role for the AARI Admin.
- Have access to Automation Co-Pilot for Business Users on the web interface.

1. Log in to Automation Co-Pilot for Business Users on the web interface.
2. [Assign members to a team](#) on page 3156.
3. [Assign teams to a process](#) on page 3157.
4. [Assign teams to a bot](#) on page 3157.

You have now assigned automations for your team. Members of your team can now automate using the iFrame widget.

For your next steps, you can configure the widget in a web application to access to automations in the iFrame widget, see [Configure an iFrame widget in a web application](#) on page 3158.

Assign members to a team

You can follow this task to create a new team and assign members to your team.

1. Navigate to **Manage > Teams**.
The **Team Setup** page appears for you to create new or edit existing teams.
2. Click **Create new team**.
The **Create a team** window appears with details for you to edit.
3. Specify the name of the team in the **Team Name** field.
4. Specify a description for your integration in the **Description** field.
5. Select the **AARI Manager** option in the **Team admin** field.
The Automation Co-Pilot manager will be the team admin that manages the user and their access.
6. Click **Create & edit**.
You will now be forwarded to the **Edit team** page where you can edit the team attributes.
7. Select the **Shared** or **Private** option in the **Request Visibility** section.
 - **Shared** option allows for all requests to be access by all member, owners, and team admins in the team.
 - **Private** option allows for the requests to be to be available to only the member who created the request, owner, and team admin in the team.
8. Navigate to the **Users** tab.
9. Click the plus (+) icon to add a users to your team.
10. Select a user or users to be added.
11. Click **Add & save**.
You have now added one or more users to your team.
12. Click **Close**.

You have successfully added users to your team. You can now add automations to the team that allows for members of your team to view and run the automations you assigned.

Related tasks

[Create a team and assign roles to team members](#) on page 3267

An AARI Manager is a team admin who can create new teams, add members to their team, and assign new team roles. AARI Admin can also configure a team but does not have a team role.

Assign teams to a process

You can follow this task to assign teams to a process.

1. Navigate to **Manage > Processes**.
The **Process Setup** page appears for you manage your process.
2. Select your existing process from the list of available processes.
For example, you select the **Ordered Items** process.
The **Edit process** page appears with details of your process.
3. Navigate to the **Teams** tab.
4. Click the plus (+) icon to assign the teams to your process.
5. Select your team or teams.
6. Click **Add & save**.
7. You can repeat these steps and add teams to another process of your choice.
8. Click **Close**.
You have successfully added teams your process.
You can now assign teams to your bot.

Related tasks

[Assign a team to a process](#) on page 3269

An AARI Admin can configure processes in the web interface and assign teams to a process for request creation. They access the web interface to view and manage processes in the **Process Setup** page.

Assign teams to a bot

You can follow this task to assign teams to a process.

1. Navigate to **Manage > Bots**.
The **Bot Setup** page appears for you manage your bots.
2. Click **Add bot**.
The **Add bot** page appears for you to add available bots.
3. Select a bot or bots.
For example, you select the **Enterprise Account** bot.
4. Click **Add** to add bot.
The bot that you selected will now be added to the bot list.
5. Select the bot that was added.
The **Edit bot** page appears with details of your bot.
6. Navigate to the **Teams** tab.
7. Click the plus (+) icon to assign the teams to your bot.
8. Select the team that you have created.

9. Click **Add & save**.
10. Click **Close**.
You have now successfully added teams your bot.

Configure an iFrame widget in a web application

You must configure iFrame widget settings in a supported web application to properly enable the iFrame widget.

Ensure you have completed the following:

- Provided a system-created **AAE_Robotic_Interface User** role for the AARI User.
- Have access to Automation Co-Pilot for Business Users on the web interface.
- Have access to the web application of your choice that supports the iFrame technology. For this task, it would be the ServiceNow Service Portal and ServiceNow App Engine Studio.

1. Log in to the ServiceNow Service Portal.
2. Navigate to the **Widget Editor** page.
This page has a few options for you to configure your widget, as well as a reference for you to view any recently updated widgets.
3. Click the **Create a new widget** option for creating new widgets.
The **Add a Widget** window appears with details for you to specify your widget.
4. Specify the name of the widget in the **Widget Name** field.
The ID of the widget will be automatically generated when you enter the name.
For example, you can name your widget **AA Bots** for reference that this is an Automation Anywhere bots widget.
5. Click **Submit**.
A new window with an HTML template or editor prompts you to enter the iFrame widget details, if applicable.

```
HTML Template
1 <div>
2 <iframe src='https://embed.aaiengineering.com/aari/#/embedded' name="aari-embedded-app" width="370px" height="650px"></iframe>
3 </div>
```

6. Paste your iFrame widget code to the **HTML** template.
This is the iFrame widget code that you had generated in the Automation Co-Pilot (web).
7. Click **Save** or press **Ctrl + S** to save the current session.
You have now added the iFrame widget code and saved your session. This is the code to embed your iFrame widget.
8. Access to the main page of the ServiceNow App Engine Studio.
9. Navigate to **All > Service Portal Configuration**
10. Click **Designer**.
11. Select an existing page to edit.
You are now directed to a designer page.
12. Optional: Rearrange or remove your existing widgets on the page, to give space for the iFrame widget.
13. Drag the widget you had created (ex: **AA Bots**) from the **Widgets** tab and place it on the page.

You have now successfully added the iFrame widget and should now be visible on the page.

Important: The iFrame widget is visible but with no styling applied.

14. Navigate back to the ServiceNow Service Portal

15. Click **Widget Editor**.

16. Click on your widget (ex: **AA Bots**) from the **Recently Updated** list.

You are now navigated to the window with an HTML template. The page should also include a CSS template.

17. Specify the widget (ex: **AA Bots**) details in the **CSS** template.

This can be the border size, style, and color of the widget.

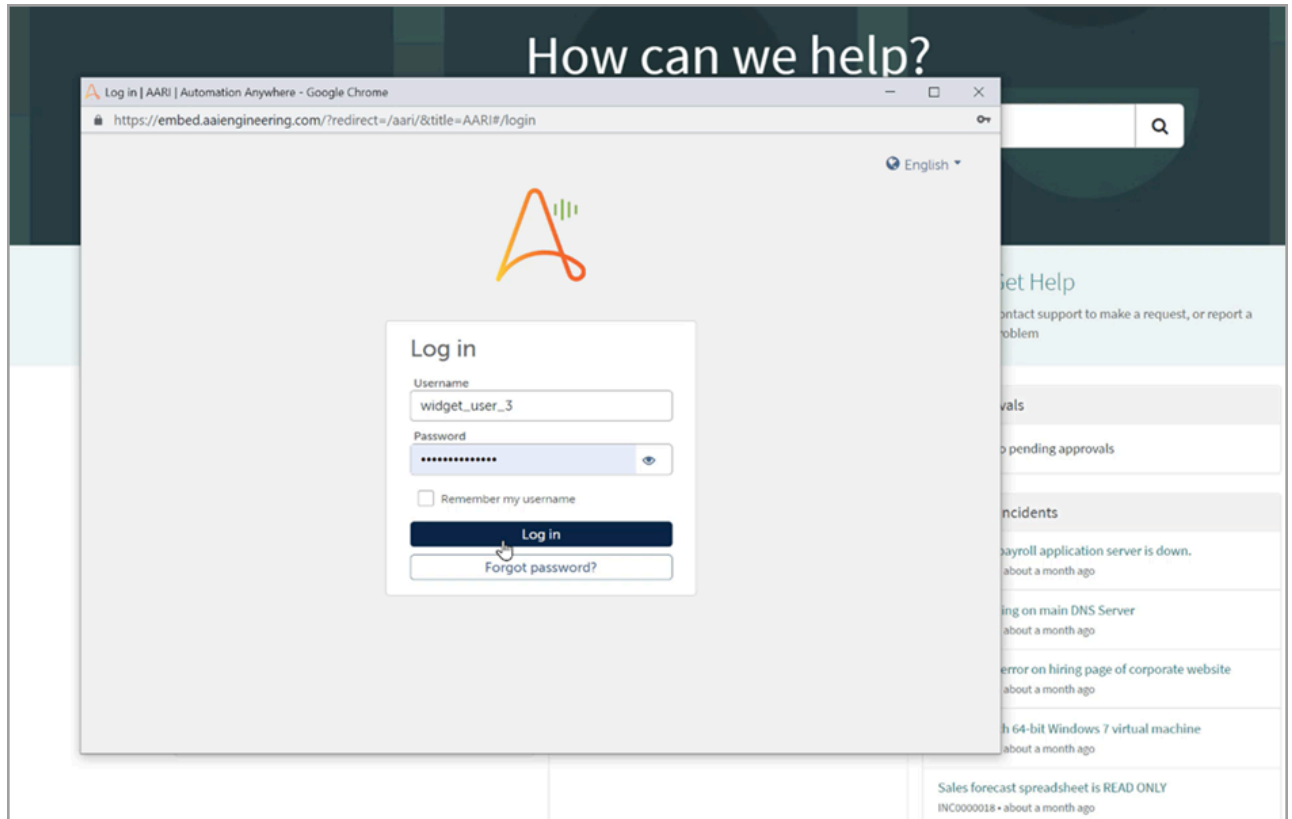

```
CSS - SCSS
1  iframe{
2    border-width: 1px;
3    border-style: solid;
4    border-color: #dee5e7;
5    border-radius: 0.4rem;
6  }
```

18. Navigate back to the designer page.

The iFrame widget structure has now been updated.

19. Refresh the page.

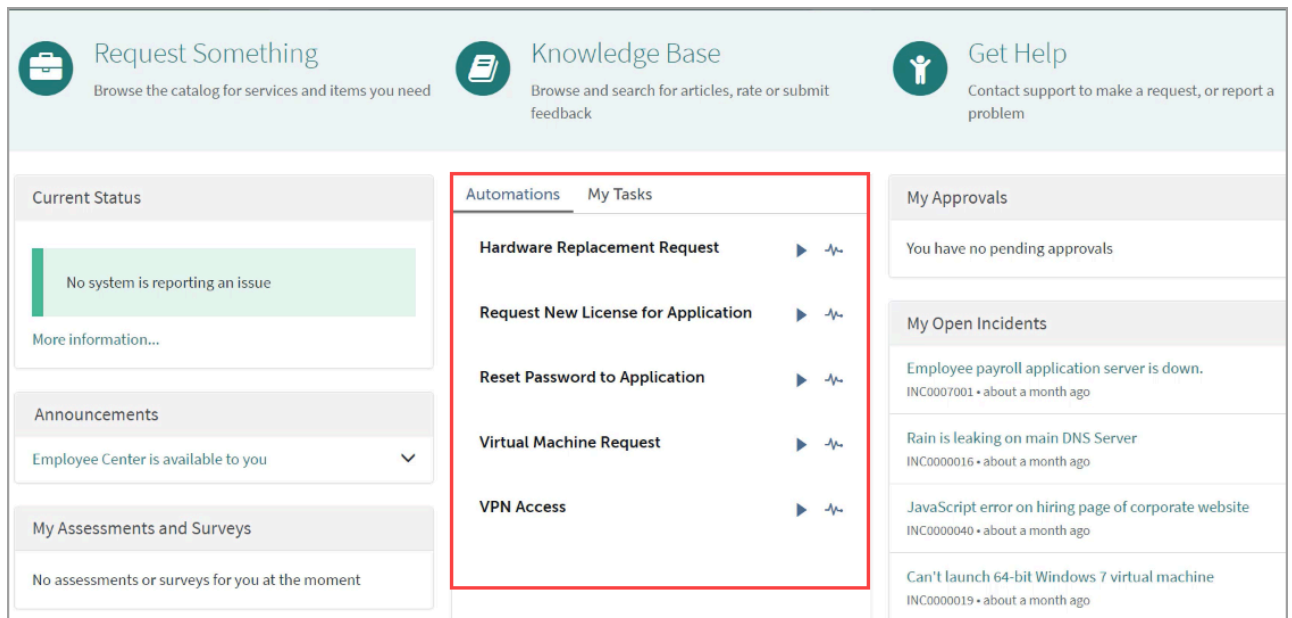

You will notice a small-sized window that appears and is connected to the Automation Co-Pilot (web) interface with a login page.

20. Log in with your user credentials to the iFrame widget in order to access your Automation Co-Pilot data.

The iFrame widget will refresh and a list of automations and tasks from Automation Co-Pilot is now available. You can interact directly with your data.

21. View the iFrame widget.

You have now successfully embedded the iFrame widget with Automation Co-Pilot data to your web application.

For your next steps, you can deploy your automations using the iFrame widget, see [Deploy automations in web application](#) on page 3161.

Deploy automations in web application

You can now automate your tasks using the iFrame widget.

Ensure you have completed the following:

- Provided a system-created **AAE_Robotic_Interface User** role for the AARI User.
- Have access to Automation Co-Pilot for Business Users on the web interface.
- Have access to the web application of your choice that supports the iFrame technology. For this task, it would be the ServiceNow Service Portal.

1. Log in to the ServiceNow Service Portal.

2. Navigate to the page(s) on which you had embedded the iFrame widget.

This can be the **Designer** portal in the ServiceNow Service Portal where you manage your data and relevant information.

3. Log in with your user credentials to the iFrame widget in order to access your Automation Co-Pilot automations.

Note: When using Automation Co-Pilot (extensions), users should open their Google Chrome extension to login.

This is the user that is assigned to a team.

The iFrame widget will refresh with a list of available automations.

4. Optional: Fill your initial forms using URL parameters.

You can modify your URL with specific query parameters, to provide more control over your specific data.

Note: Embedded Automation supports these parameters: Check Box, Date, Dropdown, Number, Radio Button, Time, Text Area, and Text Box. For more details, see [Construct URL parameters for supported elements](#) on page 3303.

5. Run your automations or complete pending tasks.

You can deploy automations using the iFrame widget in the ServiceNow Service Portal.

Note: You can run your bots with the Picture-in-Picture feature. You can enable this feature when you configured your bot in Automation Co-Pilot to run in a virtual window. See [Configure a bot](#) on page 3277.

The screenshot displays the Automation Anywhere user interface. At the top, there are three main navigation links: 'Request Something' (Browse the catalog for services and items you need), 'Knowledge Base' (Browse and search for articles, rate or submit feedback), and 'Get Help' (Contact support to make a request, or report a problem). Below these, the main content area is divided into several sections. On the left, there's a 'Current Status' section with a green bar indicating 'No system is reporting an issue'. Below that are 'Announcements' (Employee Center is available to you) and 'My Assessments and Surveys' (No assessments or surveys for you at the moment). The central focus is a 'Virtual Machine Request' form, outlined in red, with a 'Create new request' header. The form includes 'VM Details' with dropdown menus for Provider (Azure), vCPU (8), Memory (8GB), Hard Disk (200GB), Operating System (Windows Server 2019), and Expiration (15 Days). There is also a 'Business Reason' text input field. At the bottom of the form are 'Cancel' and 'Submit' buttons. On the right side, there are sections for 'My Approvals' (You have no pending approvals), 'My Open Incidents' (listing various system issues like 'Employee payroll application server is down'), and 'Assessment : ATF Assessor'.

You can construct URL parameters for the following supported elements: **Date, Number, Text Box,** and **Time.**

Automation Co-Pilot for Business Users supported features

There are more ways you can use Automation Co-Pilot.

Overview

Automation Co-Pilot using embedded widget enabled you to setup your embedded iFrame widget and run your automations, while maintaining the consistent Automation Co-Pilot experience, in your favorite web applications such as ServiceNow, Salesforce, and Genesys.

There are now more opportunities for you to get the most out of the Automation Co-Pilot experience, with additional enhancements and features.

Automation Co-Pilot in Microsoft Teams

Automation Co-Pilot allows you to bring the Automation Anywhere platform experience of running bots directly to Microsoft Teams. This allows for your business users to automate tasks

without leaving their favorite collaboration applications. This can be expanded to even more automation opportunities and improve the existing routine tasks and processes.

Enhancements

- Automation Co-Pilot can be accessed by users at anytime from their Teams apps menu in the sidebar tab. The Automation Co-Pilot app can be pinned by users to show up next to their **Activity** and **Calendar** tabs.
- When Automation Co-Pilot is deployed in Teams, this will become a web application that is available for users, as a tab application experience.
- The automation experience will always be in Teams, without needing to navigate to or use multiple applications.
- All details and statuses of your bots, tasks, and automations are in Teams.
- The automation experience in Teams provides access to all Automation Co-Pilot functionalities, such as running your automations, complete tasks from your workflows, and being alerted by proactive notifications on your important events.

Benefits

- Anyone who uses Teams can use Automation Co-Pilot.
- For any employee who uses Teams for everyday tasks, they would require access to services, such as human resources, IT, or even customer support. With a simple bot run:
 - You can create a new IT ticket to contact your IT admins quicker, without the need to access Okta or other applications.
 - You can contact HR directly and the bot establishes connection to your HR helpdesk.
 - You might need to create a support ticket to resolve a customer issue, now you can do that directly in Teams.

See the following video for an overview of Automation Co-Pilot in Microsoft Teams:

For reference of setup process, see [Integrate Automation Co-Pilot with Microsoft Teams](#) on page 3204.

Smart embedded forms and dynamic data mapping

As a developer, you can design smart forms to embed in a widget of a host web application and run a script to populate data dynamically. This saves you time to avoid repetitive data re-entry while you run your automations.

To learn more, see [Smart embedded forms and dynamic data mapping](#) on page 3166 and [Map host data to process](#) on page 3169.

Enhanced automation activities

In the embedded widget, you will find that when you run your automations (attended bots), the interface has been improved to show you better automation activities. You must have the **Manage my activity** permission as a prerequisite to use the bot controls.

Enhancements

- When you run your attended automations, its progress and execution status, as well as controls to pause, start (resume), and stop, are located in a progress page inside the Embedded Automation application.
- You can easily switch between the **Automation** tab to execute additional automations and navigate back to the progress view, to monitor the running automations
- You can view more details of your bots such as the error message, when your bots had failed, to give you a better insight into your bot status.

Benefits

- This gives you an ease of mind when you run your automations, as all the relevant controls and details of your bots are located in one place.
- The user interface make it simpler for you to run your automations.
